St. Vincent's Hospital, Stephen's Green, Dublin, was established in 1834. The hospital has 924 beds, and in connection with it there is a largely equipped dispensary, a convalescent home, and a nurse's institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospitals. The resident officers consist of a house surgeon, a house physician, and four resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases. Two gold medals and other valuable prices and certificates of merit are awarded at the end of each session. A prospectus can be had from Dr. Tobin, Stephens Green.

Dr. Stevens' Hospital, situated at Kingsbridge, is one of the oldest and largest of the clinical hospitals in Dublin, and contains over 200 beds. Recently, a very fine Nurses' Home has been added to the institution, with accommodation for over seventy nurses. And a new and thoroughly equipped dispensary and out-patient department has been completed and opened to patients. Licensing bodies recognise six months' residence in the dispensary, equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while the special ward for venereal diseases affords exceptional opportunities for the study of this most important subject.

Jervis Street Hospital, Dublin.—Jervis Street Hospital is the oldest established in Dublin. The new hospital was completed in 1866, since which time it has been opened for the reception of patients. In addition to large medical and surgical dispensaries, the out-patient department includes special departments for the treatment of diseases of the skin, eye, ear, and throat. The department of surgery employs two resident surgeons who are appointed annually. Clinical clerks and surgeons' dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve interns are appointed annually, and are provided with apartments, &c., free of expense. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons. Gold and silver medals are given after examinations held at the close of the summer session.

SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in-Hospitals. Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the Royal Eye and Ear Hospital), Dorset Hospital, the Brompton Hospital, the Orthopedic Hospital, and the Children's Hospitals in Harcourt Street and in Temple Street.

The Rotunda Hospital.—This, the largest and best-known lying-in hospital of the United Kingdom, is yearly becoming more appreciated as a school of midwifery, and as affording peculiar advantages both to the student and the practitioner for acquiring a thorough knowledge of gynecology. It contains two distinct departments—viz., the lying-in hospital, into which about 1,800 patients are admitted annually, and the hospital for the treatment of diseases peculiar to women, into which some 300 patients are now admitted during the course of the year. The present medical director is Dr. Barnet, formerly the pupil of Professor Syme, and a keen student of midwifery. He is a member of the gynaecological department at the Adelaide Hospital. There is a large external maternity in connection with the hospital, more than 2,000 women being attended during the past year. The hospital is devoted, and both students and midwives are granted a diploma on passing an examination. Students have access to a fully equipped Pathological Laboratory under Dr. Neville's direction. Two clinical clerks, at a salary of £30 per annum each, are appointed every six months from among the students who have attended the full course of instruction in the hospital. A considerable number of female pupils are also yearly trained as nurses and midwives.

Coombe Lying-in Hospital.—This hospital, which has been rebuilt and considerably enlarged, and contains 700 beds, was founded in 1826 by Mrs. Boyle, and was incorporated by Royal Charter in 1857. This hospital is situated in the centre of a district densely populated by the poorest of the community, and thus affords the best opportunities for practical instruction. There are about 800 labour cases within its walls, while those attending as externs amount to more than 2,000 in number. Moreover, the gynecological hospital for the reception of cases of the diseases peculiar to women gives admission to nearly 500 patients annually. A new wing for gynecological cases has been added. The fee for attendance is £8 8s. for six months as extern, and £18 18s. as intern pupil. During that period, the pupil attends on given days and nights in each week, and takes charge in his turn of any case that may be admitted to the labour wards, or may call for his assistance outside. A clinical clerkship is obtainable half-yearly by all pupils who obtain their diploma from the hospital, and special certificates are given. Lectures are delivered in the hospital, and clinical instruction is given daily at the bedside. Nurses who take the usual hospital course of six months are given diplomas in midwifery, and obtain their diplomas on the termination of the course.

National Maternity Hospital.—This institution, under the mastership of Dr. Barry and Dr. A. Horne, is situated in Holles Street.

Sir Patrick Dun's Maternity.—This is a branch of Sir P. Dun's Hospital, and is under the management of the King's Professor of Midwifery in Dublin University. The institution is at present in process of being re-organised.

Cork Street Fever Hospital is the only special fever hospital in Dublin. It is supported mainly by an annual Government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer session to those who desire a special course in fevers. All particulars may be obtained on application to the Registrar and Resident Medical Officer.

*The National Children's Hospital for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, is capable of containing 50 beds for the reception of cases of most of the other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Mr. Ormsby, F.R.C.S.I.

The Incorporated Orthopedic Hospital of Ireland.—This hospital was founded in 1876, and contains 65 beds. It is available for every class of deformity amenable to treatment. Particulars may be obtained on application to Mr. R. L. Swan, F.R.C.S.I., 32 Stephens Green.

The Royal Victoria Eye and Ear Hospital consists—until the new combined hospital shall be opened, which is about to be built on a new site near the Town Hall—of two institutions, viz., the former, given special instruction in ophthalmology, separately. They are:—(i) St. Mark's Ophthalmic Hospital and Dispensary in Limerick Place. This hospital was founded by Sir William and Lady Cole and contains 50 beds. Clinical lectures are delivered every morning, and operations are performed daily as occasion requires. Instruction in aural surgery is also given. (ii) National Eye and Ear Infirmary, 11 Temple Street.—This hospital contains 30 beds. Clinical instruction in diseases of the eye, including the use of the ophthalmoscope, is given daily. Operations at 12 o'clock. Instruction in surgical pathology is given daily. Afternoon classes for practical instruction in the use of the ophthalmoscope, &c., and for the demonstration
of cases, are formed from time to time by the assistant surgeons.

The Incorporated Dental Hospital, Lincoln Place.—This handsome hospital, recently erected, is the only special Dental Hospital in Dublin. It is one of the leading dental hospitals of Dublin, and has a large clientele and extensive practice among the Dublin poor. The fees are £1 15s. for the first year’s study, and £2 12s. for second, and proportionately smaller fees for shorter periods.

The City Hospital for Diseases of the Skin.—Senior students are admitted free to the practice of this hospital, which has a large out-patient attendance (nearly 7,000 for year ending August, 1902). Classes of instruction in the use of the Finsen light and X-ray treatment as applied to dermatology, with demonstrations on cases already undergoing treatment, will be held at regular intervals during the winter and summer sessions.

Belfast Hospitals.

Hospital for Sick Children, Queen Street.—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879. The hospital consists of a medical ward with eighty beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and from certain diseases, are admitted as in-patients. A very large extem is conducted in the out-patient department between the hours of 9 and 10 a.m., where children from birth to 14 years are attended to. The convalescent home, which is situated at Newtownards, contains fourteen cots, and its situation and equipment render it an admirable adjunct to the after-treatment of the cases admitted to the hospital. During the winter session every day, consultation of lecturers is given, and the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Friday of each week at 9 a.m.

Mater Infirmorum Hospital.—Established 1883. 160 beds.

The Belfast Maternity Hospital (Incorporated).—Established 1894. 16 beds. The practice of the Maternity Hospital, the certificate of which is recognized by the Royal University, &c., &c., is open to students. The fee for the session is £2 2s. Resident nurses are also received for training for a period of six months, and a diploma given which is recognized by public authorities for such an appointment as Matron. During the year 1902, 312 patients were treated in the hospital, and 251 patients at their own homes. Besides this, 538 patients were dealt with in the special department. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff, or on before November 1st and May 1st.

Ophthalmic Institution and Eye and Ear Hospital, Great Victoria Street, Belfast.—Established 1844. New hospital erected, 1857. New extem department and operation theatre added, 1902. This hospital is situated on the main road between Queen’s College and the Royal Victoria Hospital. It contains about thirty beds for intern patients, and a large external department. The latter is open on Monday, Wednesday, and Friday at noon for eye cases, and on Monday and Thursday at noon for ear and throat cases. Special instruction is given during the winter and summer sessions, but students can enter at any time, and can always obtain plenty of practice in ophthalmoscopic work. Full particulars may be had from Dr. Cecil Shaw, 16 College Square East, Belfast.

Royal Victoria Hospital.—Established 1814; incorporated by Royal Charter, 1875 and 1898. 209 beds; Convalescent Hospital, 30 beds; Children’s Hospital, 40 beds; Consumptive Department, 10 beds.

Ulster Eye, Ear, and Throat Hospital.—Established 1871. New hospital opened 1874. 30 beds.

Ulster Hospital for Children and Women, Mountspotting, Belfast.—The leading hospital in the large part of the city situated on the County Down side of the river. It is placed in a working-class district, and has a great field for its charitable operations. There are in the hospital about twenty-two beds for children and eight for women. There is an extem department for children open every week-day, except Saturday, from 9 till 10, and for women at 11.30, and a special department for diseases of the eye, ear, and throat on Tuesdays and Fridays from 9 till 10. During the summer and winter sessions, clinical instruction is given to students daily, operations being chiefly performed on Wednesday and Saturday. There is a resident midwife for external work, and every facility is afforded students for attending their cases in the district.

Cork Hospitals.

County and City of Cork Hospital for Women and Children.—Established 1874. 90 beds.

County and City of Cork Lying-In Hospital.—Established 1798. 17 beds.

Eye, Ear, and Throat Hospital, Western Road.—Incorporated 1898. 35 beds.

Fever Hospital, and House of Recovery.—Established 1801. 110 beds.

Maternity.—Established 1872.

Mercy Hospital.—Established 1857. 80 beds.

North Charitable Infirmary.—Established 1774. 110 beds.

Cork South Infirmary and County Hospital.—Founded 1773. The hospital contains 100 beds, available for clinical instruction, 40 medical and 60 surgical. There are special wards devoted to the treatment of diseases peculiar to women and children, and a large medical and surgical extem department. Clinical instruction is given daily during the session from 9.30 to 11.30, both in the medical and surgical wards, and clinical lectures are regularly delivered.

The operation and sterilising rooms are thoroughly up to date. The X-ray department is fully equipped with the newest apparatus necessary for such work. Students are regularly instructed in the methods of using the rays by practical demonstration on the cases requiring their use.

The hospital has been largely availed of by students o’ the Cork School of Medicine.

Galway Hospitals.

County Hospital.—Established 1876. 60 beds.

Irish Public Services.

The Poor-law Medical Service.

Since the early part of 1890, a vital change has taken place in the Irish Poor-law Medical Service—the service which has, heretofore, absorbed most of the Irish rising medical generation. By the Irish Local Government Act the administration of the system, the appointment and payment and allocation of duties of medical officers was transferred from the old Boards of Guardians, composed in due proportion of members elected by the local voters and members who acted ex-officio in virtue of property qualifications, to new boards composed wholly of the elected representatives. This change has had the most disastrous effect upon the service. The ex-officio guardians, i.e., the local gentry, were thereby eliminated, and the sole control of the service has been transferred to the elected Guardians, who have, we regret to say, failed to give even a shadow of the attention to it that everything—before the welfare of the poor, and before the just rights of the medical officer. Questions of religion and politics are so rampant on Irish elected Boards that the medical officer is at the helm, in these matters with the majority of the Board who governs him has not a pleasant life. The Irish Medical Association, whose work it is to safeguard the interests and improve the condition of the Poor-law Medical
IRISH LEAGUE. We need not— we trust— point out to any member of the medical profession that to endeavour to obtain a post on such a qualification is to commit an act which is unworthy of his profession.

Duties.—The duty of the dispensary doctor is two-fold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensary doctors in the district, and they relieve one another at stated intervals, for which he will hardly receive more than £200 a year. As often as may be necessary to terminate the case. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in many districts he has to make up all the medicines for the poor.

The pressure of these duties is in a great degree dependent on the goodwill of the guardians. If the medical man be a favourite with his masters they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour in which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance. If they are in a hurry, however, and have some interest to differ from the guardians in religion or politics, his position may become impossible. He may be peremptorily summoned in any weather, at any hour, and to a distance he may probably know to be altogether trivial, or to a person whom he may know to be perfectly well able to pay.

Workhouse Hospitals.—The number of unions in Ireland in 159, to each of which is attached a medical officer, who is appointed and controlled by the board of guardians in the same manner as the dispensary surgeon. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or long journeys across the country are involved.

THE IRISH LUNATIC SERVICE.

This service, at present, affords a comfortable livelihood for 22 Resident Medical Superintendents and 32 Assistants. The Superintendents receive salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the Assistants receive salaries as ranging about £200 a year. There are also Visiting Physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The Superintendents and Assistants must devote their whole time to their duties.

Heretofore the appointments of Medical Superintendents have been in the patronage of the Lord Lieutenant, but, under the new Local Government Act, they are in the hands of the County Councils, with the proviso that no one shall be appointed who is not a fully registered practitioner with five years' service as Assistant. The Assistance has been, heretofore, appointed by the Board of Governors, and will, in future, be appointed by the Committee of the County Council to which the management of the asylum is entrusted. In addition to these officers, there are, in certain larger institutions, Clinical Resident Officers, who receive about £50 a year and full allowances. These appointments afford an excellent introduction to the higher places in the service, but poor enough to both warehouse and dispensary lies with the guardians, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter largely into the election of Poor-law medical officers. Family interests also possess great weight. In Ireland, moreover, an attempt has been made to insist upon the candidate being a member of the United Irish League.
not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of the Royal Irish Constabulary, who usually acts upon the advice of the local District Inspector. It is to the convenience of the men, and, of course, the emoluments depend on the number of Constabulary stations and the number of men in each.

The Cost Guard Service.—The duty of the Medical Officer is to attend the men when on half pay and to examine candidates either for admission or for supernumeration. The fees vary from 5s. to 2s. 6d. per visit. The appointments rest with the Admiralty, but are usually secured for the local Poor-law Medical Officer. In this case, also, emoluments depend on the number of stations and men.

Factory Surgeonies are in the gift of the Chief Inspector of Factories in Whitehall. There is a set scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to, and, in some districts, at all events, the emolument is a matter of arrangement. The amount depends upon the size of the factory, the position being, in Dublin or Belfast, or in other large manufacturing centres, a lucrative one, but in other places scarcely worth taking. The attendance on the military depots is not worth mentioning.

The names of the Professors, Lecturers, and Hospital Staffs of the following Schools and Hospitals are not included in this place, being found in the advertisement of each institution, as indicated below.

Scotland.

Scotland still maintains her educational system at the high level to which it long ago attained, and, with a considerably less numerous population inhabiting her whole area than that of London alone, supports four venerable and historic Universities, each with an honoured past and a magnificent record. The Universities of Edinburgh, Glasgow, Aberdeen, and St. Andrews have sent forth many illustrious graduates in all the different branches of higher learning; few schools can show more gratifying results, and, now that the Carnegie Bequest is in full working order, a University education is within the reach of every Scotch lad, save the very poorest. In Edinburgh and Glasgow those who do not aspire to the honour of a University degree can obtain college diplomas and excellent medical teaching from extra-mural schools of almost equal renown.

The inhabitants of Scotland have always evinced a deeply-rooted dislike for constraint; the regulations of their Universities exemplify this. The student in Scotland is his own master; he lives where he likes, dines where he chooses, and can clothe himself in any kind of garment he chooses. In but one of the Universities have students to don gowns. No doubt the great freedom granted to students occasionally leads to unsatisfactory results, but the advantages which accrue from the system may be held to more than counterbalance the drawbacks. The student is only required by the authorities to attend with due regularity without compulsory classes, to give evidence of diligence in his work, and to conduct himself with proper decorum—while within the University precincts. Several halls of residence for students have lately been established, but even here the students are their own masters. Absence of residential colleges implies the absence of college fees, and of the invariable large extras incurred by college life.

The co-existence of teaching and degree-granting Universities and extra-mural medical schools in Scotland forms one of the most important factors in the system of medical education in the country. That obtainable at the Universities is the best of its kind, comprising courses on all branches of special medicine and surgery; at the extra-mural schools the special subjects are perhaps even better treated, as they are taught by specialists themselves. In the way of expense, there is little between the University course and the obligatory curriculum for the Licence of the Colleges. The minimum cost for five years' attendance for the licence may be put down at £120, which includes class and examination fees; and at the Universities at £146, a difference of about £25 a year only.

Perhaps the one blot upon the Scottish system of medical education at Universities arises from the plan adopted at their professional examinations of dividing the examiners' duties to the professors themselves, along with only one coadjutor for each subject. As University students are now allowed to attend one-half of the total number of courses required for graduation outside the University walls, it happens now and again that those that have done so in a subject, upon which they are examined by the professor teaching it, are placed at a disadvantage in not being thoroughly conversant with subjects specially lectured on by examiners during the preceding session. The examining board for the diploma of the Scottish colleges, indeed, is largely made up of the extra-mural lecturers, but the number assigned to each subject is large enough to avoid the examination of a candidate by his own teacher in the majority of instances.

Apart from the educational attractions offered to students of medicine by the Scottish schools, a very important fact aids in explaining the reason why so many students from all parts of the Empire enrol their names in their books; the cost of maintenance is less than in England or Ireland. As a general rule the higher the latitude the cheaper is the living in Edinburgh and Glasgow are more economical than London and Dublin; Aberdeen still less expensive.

THE CARNEGIE TRUST.

Through the munificence of Mr. Andrew Carnegie, L.L.D., payment is now made ‘‘of the whole or part of the ordinary class fees exigible by the Universities from students of Scottish birth or extraction, and of sixteen years of age or upwards, or scholars who have given two years’ attendance, after the age of fourteen years, at State-aided schools in Scotland, or at such other schools and institutions in Scotland as are under the inspection of the Scottish Education Department.’’

The Trust provides for the payment of the class fees of the above students proceeding to graduation in medicine or science. Application for payment of class fees under the conditions of the Trust should be made to the Secretary, Mr. W. S. McCormick, Merchants' Hall, Hanover Street, Edinburgh.

Scholarships, Fellowships, and Grants in aid of original research are now awarded annually by the Trust. For particulars, conditions, &c., apply to the Secretary.

UNIVERSITY OF EDINBURGH.

Four degrees in medicine are granted: Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of
Medicine and Bachelor of Surgery who has not been engaged in medical and surgical study for five years, after passing a preliminary examination in general knowledge in accordance with the medical ordnances. At the University of a Dutch or German University is held to supersede such preliminary examination. The subjects included in this general examination are English grammar and composition, English history and geography, Latin, arithmetic and the elements of mathematics, and, in addition, all the optional subjects, Greek, French, or German.

The annus medicus of each year is held to be constituted by at least two courses of not less than one hundred lectures each, and two courses of not less than fifty lectures each, exclusive of the clinical courses, in which lectures are given twice a week during prescribed periods. Two years of the five years must be spent at the University, the remaining three years at any University of the United Kingdom, or other Universities or Medical Schools recognised by the University Court.

During the first four years the student must attend elementary botany, elementary zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence during courses of not less than 2½ months each; public health, not less than thirty lectures; practical anatomy, during two courses of not less than fifty lectures each; chemistry, anatomy, physiology, pathology, surgery; materia medica and therapeutics, medicine, and midwifery and the diseases of women and children during courses of not less than five months each. Eight of these subjects must be taken at a University or college affiliated to a University entitled to grant the degree of M.D. He must attend a course of twenty-five lectures on practical pharmacy in a University or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. He must attend one course of ninety-six lectures in the course of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society.

During the fifth or final year he must be engaged in clinical study for at least one year in attendance on a hospital, or in scientific work bearing directly on his profession, or in the military or naval medical service, or for two years in practice other than purely surgical. The candidate or candidates admitted shall submit to the Faculty of Medicine a certificate issued by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor in Surgery, which he may have made a subject of study after having received those degrees. The candidate will also be examined in clinical medicine and must show practical acquaintance with advanced methods of diagnosis; he may take, at option, gynaecology, mental diseases, or diseases of children for one of his three cases. The degree of M.D. is conferred on holders of the degrees of M.B. and Ch.B., or M.D. and Ch.B., and on submission of a thesis approved by the Medical Faculty, provided that the candidate shall have passed the medical preliminary examination in the subjects of Greek and logic, or moral philosophy. The candidate elect to do so, he may, however, take the M.D. degree under the new regulations, i.e., substituting an examination in clinical medicine for that in Greek and logic. This course is usually pursued by those who did not pass in these subjects with the rest of their preliminary examinations.

The regulations for the degree of Ch.M. are very similar, the candidate being examined in surgical anatomy, operations on the dead body, clinical surgery, and some of the special branches.

Candidates settled abroad, who cannot appear personally to receive the degree, may, after satisfying the Senate to that effect, have the degree conferred on them in absentia.

Fees:—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas, and the proportion of this sum to be paid by a candidate at each division of the examination is registered from time to time in the University Court. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas (old regulations, £5 5s.).

The total expenses of the curriculum, including examination and matriculation fee, is £146.

Bursaries and scholarships open for Session 1903-1904: Among the bursaries and scholarships open during the ensuing year are the New Zealand Fellowship of £100 in Anatomy, and Physiology, and Pathology. Allan Fellowship of £48 13s. in Clinical
Medicine and Surgery. Heriot bursaries, applications to Treasurer, 20, York Place, before September 15th. Stark scholarship in Clinical Medicine, value £112. Mackay Smith scholarship in Chemistry, value £25. Tutorships for students in a second and third year of medicine, whose pecuniary circumstances need assistance. Applications to Dean by October 1st. Four Buchanan bursaries. Two Sibbald bursaries of £30 a year for three years, particulars from Messrs. Mackenzie, Innes, and Co., 23 Queen Street, Edinburgh, before September 15th. Two Thomson bursaries of £25 for one year, one conferred at each preliminary examination in October and March. Three Grierson bursaries (£100) (offices of Crawford and Leadbe, Victorian Offices, Edinburgh, before September 15th. Two John Aitken Carlyle bursaries of £28 for one year for proficiency in class examinations in anatomy and physiology. Four Mackenzie bursaries of £20, in practical anatomy. Renton bursary of £40 for one year, for students attending classes of natural philosophy, mathematics, chemistry, or political economy, who also can show they are in need of pecuniary aid. Two Crichton bursaries of £50, for four years, one competed for at each preliminary examination. Buchanan scholarship of £40 tos., for proficiency in midwifery and gynaecology, as shown by class work and oral examination in rooms. The scholarships are:—The James Scott, £42 10s. annually, in midwifery; the Ettyles, £31 5s. annually to the most distinguished graduate; two Hope prizes, £50 annually in two Crimond bursaries, £20 annually. Research in anatomy and physiology. One Vans Dunlop scholarship in preliminary subjects, value £100. Mouat scholarship in practice of physic, about £55. Houldsworth scholarship in Pharmacology, £40.

General Education. The University of Edinburgh also possesses a Faculty of Science which may confer two degrees, Bachelor of Science (B.Sc.), and Doctor of Science (D.Sc.). These degrees are given in pure science subjects, and candidates for the degree of B.Sc. in pure science must attend at least seven courses of instruction in the subjects selected by them during the course of not less than three academic years. These courses must be prescribed for the first science examination, and four on those for the final examination. Four of these courses must be taken in the University of Edinburgh. The subjects for the first science examination are:—1. Mathematics; 2. Natural philosophy; 3. Chemistry. For the second examination they may be selected from the following: Mathematics, physics, physics, anatomy, physiology, zoology, botany. Graduates as B.Sc. may, after five years, proceed to the degree of D.Sc., undergoing an examination in the subjects chosen, and presenting a thesis founded on original work.

Graduation in Public Health: Similar degrees are conferred in Public Health. Candidates must be graduates in medicine of a University recognised by the University Court, and must matriculate for the course in which they proceed for examination. Before proceeding to the first examination they must produce evidence that (1) they have worked at least twenty hours a week during a period of not less than eight months, after taking their medical degree, in a recognised Public Health laboratory. Five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh, and (2) they have attended a course of lectures on physics in addition to that qualifying for graduation in medicine, and one of at least three months' duration, on geology, such as the Board of Supervision approves.

Candidates for the second examination of B.Sc. in Public Health are not admitted until at least eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two separate courses of Public Health, of at least forty lectures each, one dealing with medicine, the other with engineering, each in its relation to public health, in such manner as the Senate shall determine. They must also have studied practical sanitary work under a Medical Officer of Health for six months, and have attended a two months' instruction in a sanitary hospital, and a one months' instruction in measurement and drawing.

Full details of the subjects included in the different courses are given in the official programme of the Faculty of Science, which may be obtained from the University (price 2d.).

In a similar manner to that described under degrees in pure science, a B.Sc. may after five years proceed to take the degree of D.Sc. in Public Health.

Fees for Science Degrees: B.Sc., first examination, £3 3s.; B.Sc., second examination, £3 3s.; D.Sc., £10 10s.; total, £16 16s.

University Hall, Edinburgh.—In an educational number it is worth while to call attention to the advantages now offered to students coming to Edinburgh to study, in the shape of social residences akin to, though very much less pretentious than, the English University colleges. During the past six years several buildings have been acquired in Edinburgh for this purpose, in which students can live in a self-governing community. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges vary from 7 to 14s. per week. The residents elect a treasurer from among their number who acts as intermediary between them and the housekeeper or servants. It is a satisfactory arrangement for the betterment of the health of the students. These students now live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents. These are considered and noted on at a house meeting. In all disputed points Professor Geddes is the referee, while Dr. Ricardo Stephens is the rent treasurer, who will supply any further information required. The Hall is an admirable place for parents to send their sons to, and in applications for the B.Sc. students may be expelled by a meeting of the residents similar to that held for elective purposes.

Medical School for Women.—The medical teaching of women in Edinburgh is carried on by the Scottish Association for the Medical Education of Women (the Secretary, Minto House, Chambers Street). The classes are conducted by the lecturers of the Medical School of the Royal Colleges, and qualify both for the Edinburgh University degree, and for the Board of Education Triple Board. The classes are for women only. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes or without special courses. Women students are eligible for the benefits of the Carnegie Bequest.

UNIVERSITY OF GLASGOW,

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but eight of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations, laid down in Ordinance No 14, Glasgow No. 1, of the Commissioners under the Universities (Scotland) Act, 1889, four degrees, open both to men and to women are conferred—M.B. and Ch.B. (always combined) and D.M. and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Elementary mathematics, and (4) Greek, French, or German, with possible option to students whose native tongue is not English in the case of the fourth subject, and on passing, all students must register in the books of the General Medical Council. By a regulation recently enacted, it is no longer compulsory to pass in all the four preliminary subjects at once, and they may now be passed at two stages. For M.B. and Ch.B. a curriculum of five years is required. The curriculum closely resembles that at
Edinburgh. The "University Calendar" should be consulted for details.

The fees for M.B. and Ch.B. are £23 2s., and the present fee for hospital attendance is £21. The fee for M.D. is £10 10s., and for Ch.M. is £10 10s.

Bursaries and prizes to the annual amount of about £600 are appropriated to medical students, including an Annual Competency prize for women, £25 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and scholarships and Fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course.

Queen Margaret College for Women.—Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1875) and still in existence, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B. and Ch.B. is given by University professors and lecturers, with excellent facilities for hospital and dispensary work in the Royal Infirmary and other hospitals. A Hall of Residence for the students was founded six years ago. Fees for the classes at Queen Margaret College may be paid by the Carnegie Trustees.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, Agriculture, and in Education. It is, moreover, a teaching body equipped with twelve distinct chairs in the various branches of medicine and surgery, besides a Lectureship in Tropical Medicine. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of the study is nearly the same as in the University of Edinburgh; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, the candidate for the degree of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Class fees, £3 3s. each. Total cost, exclusive of the fees for degrees, is about £100. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice is only £6. The professional examination for the Bursary, held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions.

Bursaries.—Bursaries, scholarships, and Fellowships to the number of fifty, and of the annual value of over £1,150, may be held by students of medicine. See "University Calendar."

THE DEGREE OF M.D.—The degree of Doctor of Medicine may be conferred on the completion of the degrees of M.B. and C.M. (Old Regulations), is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years in attendance in a hospital, or in medical and surgical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates for the degree of M.D. (New Regulations) are required to pass an examination in clinical medicine in addition to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine in any University in the United Kingdom. Regulations may be seen in the "Calendar," or obtained on application to the Secretary of the Medical Faculty.

Aberdeen Royal Infirmary.—This is a well-equipped institution, containing 240 beds, and affords excellent opportunities for clinical study to students at the Aberdeen University. The city, moreover, offers inducement in the way of cheaper living and a comparatively quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

ST. ANDREWS UNIVERSITY.

United College St. Andrews and University College, Dundee.

This University (session opens October 9th) grants the degrees of M.B., Ch.B., M.D., and Ch.M. The degrees of the University are open to either sex. For the degree of M.B., Ch.B., two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The preliminary examination and the professional examination are of the same character as in the other Scottish Universities. A Diploma in Public Health is also granted by the University of St. Andrews to graduates in medicine in any University in the United Kingdom. Twelve months must elapse between the date of graduating in medicine and entering for the examinations for the diploma. The course of study required consists of (1) six months' clinical work in the hospitals, with a special study of anatomy, and the pathology of diseases transmissible from animals to man in a laboratory of the University of St. Andrews; (2) six months' work with a medical officer of health; (3) three months' clinical instruction in infectious diseases. Subjects for first examination:—Chemistry, physics, bacteriology, and meteorology. Second examination:—Sanitation, sanitary law, vital statistics, medicine in relation to public health.

University College, Dundee.—The University of Dundee, was affiliated and made to form part of the University of St. Andrews on January 15th, 1897, and the whole medical curriculum may be taken in the College. The United College, St. Andrews, offers two classes for the first two years of professional study.

Bursaries and Scholarships.

United College, St. Andrews.—Malcolm bursary £25 a year. Two Berry bursaries of £40, tenable for three years, open to men for arts, science, or medicine. Fourteen Taylor-Thompson bursaries, £50 to £50, tenable for one year, partly for two, open to women only proceeding to graduate in medicine.

University College, Dundee.—Eleven entrance bursaries of £15, open to women for arts, science, or medicine, tenable for one year. Four £20 and three £15 second year bursaries for men or women in arts, science, or medicine, tenable for one year. Four £20 and two £15 third year bursaries for men or women in arts, science, or medicine, tenable for one year. Two Educational Trust bursaries of £25, tenable for three years. Applicants must have attended a public or State-aided school in Dundee for at least one year before examination. Bute bursary, annual income from £75.

Preliminary Examinations.—The dates of the next two examinations are September 26th, 1903, and March 26th, 1904. Schedules (obtainable from the Secretary of the University) to be returned filled up, and fees paid by 1st September, 1903, and by 1st March 27th, 1904.

Fees for Degrees.—Total fees for M.B., Ch.B., are the same as at other Scottish Universities, i.e., 22 guineas (payable in instalments). Fee for the degree of M.D.
and also for that of Ch.M., is 10 guineas each in case.
For the Diploma of Public Health examinations the fee is £5 3s. for each of the two examinations.

Class Fees.—The fee payable in each of the following separate classes is 3 guineas, viz., (a) Chemistry, Physics, Zoology, Botany, Physiology, Practical physiology, Anatomy, Practical anatomy, Materia medica, Practical pharmacy, Pathology, Practical pathology and Bacteriology, Medical jurisprudence, Public Health, Medicine, Surgery, Operative surgery and Midwifery.

In Clinical Medicine, Clinical Surgery, Ophthalmology, Diseases of Throat and Ear, and Mental Diseases the class fees are 2 guineas each, and in Peers 1 guinea.
For the Chemistry required for the D.P.H. the fee is 7 guineas. A special class is also held for the D.P.H., for which the fee is 3 guineas.

Dundee Royal Asylum.—The appointments include a qualified resident assistant and two resident clinical clerks. Clinical instruction is given.
Further information will be found in the Calendar of the University, published by Messrs. Blackwood and Sons, at the Medical Faculty, Professor Weymouth Reid, F.R.S.

Dundee Royal Infirmary.—The Infirmary contains 300 beds, with a special ward for the treatment of chronic cases. No resident specimens are admitted annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. Out-patients are seen daily at 9 a.m.

The instruction provided is on one course of examinations by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. The Tuition Fee for the Infirmary, £2 2s. each session, or £3 3s. a year. Further information on application to the Medical Superintendent.

THE COLLEGES.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after a series of examinations, the student may obtain the diploma of the co-operating bodies.

The holders thereof are enabled to register three days' residence under the Medical Acts, viz., Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow. The diplomas are also recognised by the Army, Navy, and other public bodies.

The three co-operating bodies grant their single qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery, as the case may be.

REGULATIONS OF THE CONJOINT BOARD OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND THE FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The candidate must produce certificates of having attended the following separate and distinct course of lectures, the certificate distinguishing the session in which he has severally attended. Anatomy, one course, six months. Practical anatomy, twelve months. Chemistry, one course, six months. Practical or analytical chemistry, one course, three months. Materia medica, one course, three months. Physiology, one course, six months. Practice of medicine, one course, six months. Clinical medicine, nine months. Principles and practice of surgery, one course, six months. Clinical surgery, nine months. Obstetrics, one course, three months. Medical jurisprudence, one course, three months. Pathological anatomy, one course, three months. The candidates must also produce the following certificates:—(a) Of having attended not less than six cases under the supervision of the practitioner who signs the certificate, who must be a registered medical practitioner. (b) Of having attended for three months' instruction in practical pharmacy. The certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of a laboratory, dispensary, or a registered practitioner who dispenses medicine to his patients, or a teacher to a class of practical pharmacy. (c) Of having attended for twenty-four months the medical and surgical practice of a public general hospital, containing on an average at least eighty patients, and possessing distinct staffs of physicians and of surgeons. (d) Of having attended, for six months, the practice of a public dispensary specially recognised by any of the co-operating colleges, of having been engaged for six months as visit-assistant to a registered medical practitioner. (e) Of having been instructed in vaccination.

First Examination, Fee £5.—The first examination shall embrace chemistry, comprising the following particulars:—Chemical physics, heat, light, and electricity; the principal non-metallic and metallic elements, and their more common combinations, also the leading alcohols, organic acids, ethers, carbohydrates, and alkaloids; the candidates will also be examined practically in testing; physics and elementary biology. The first examination shall take place not sooner than the end of the first year, including a winter term. Candidates who desire to enter for the first professional examination must apply to the Inspector of Certificates on or before the Friday preceding the day of examination, and must produce certificates of attendance on one course of studies in chemistry, one course of anatomy, and six months' practical anatomy.

Second Examination, Fee £5.—The second examination shall embrace anatomy and physiology, and shall not take place before the termination of the summer session of the second year of study. Candidates must produce to the Inspector certificates of attendance on the prescribed courses of anatomy, practical anatomy, and physiology.

Third Examination, Fee £5.—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

Final Examination, Fee £15.—The final examination shall embrace the principles and practice of medicine (including therapeutics and medical anatomy, clinical medicine): the principles and practice of surgery (including surgical anatomy and surgical pathology); chemical surgery; midwifery and gynaecology; medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education:—(1) English language, including grammar and composition; (2) Latin, including grammar, translation from scripture, and translation of easy passage not taken from such authors; (3) elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions; (b) algebra, including simple equations; (c) geometry, including the first two books of Euclid; (d) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (e) one of the following optional subjects:—(a) Greek; (b) French; (c) German; (d) Italian; (e) any other language; (f) logic; (g) botany; (h) zoology; (i) elementary chemistry.

Qualification in Public Health: The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

For the pursuit of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson, 48 George Square, Edinburgh; and for those of the Royal College of Physicians, to Dr. R. W. Philip, 45 Charlotte Square, Edinburgh.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candi-
date must have been a member of the college for at least three years previously, and have attained the age of twenty-seven years.

The Membership is conferred only on a licentiate of a college of physicians or graduate in medicine. The candidate for membership, provided he shall have attained the age of twenty-four years and shall have passed an examination (1) On the principles and practice of medicine, including therapeutics; (2) On one of the following subjects, to be selected by the candidate, for a high standard of proficiency is expected: (a) one or more departments of medicine specially professed; (b) psychological medicine; (c) pathology; (d) medical jurisprudence; (e) public health; (f) midwifery; (g) ophthalmology. The examination is of a searching character extending over three days, the first of which is devoted to the examination of patients, vis a vis clinical and practical examination on methods of diagnosis — microscopy of blood, clinical bacteriology, quantitative analysis, etc., and written commentary on a case examined. The second day is taken up by written papers, and the third by practical examination on special subject and oral examination.

The fee for membership is 35 guineas, for fellowship 38 guineas, with a stamp duty of 25s — £10 13s. 4d. all in.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations for this licence are held on the first Wednesday of each month, save those of September and October, on medicine, materia medica, midwifery, and medical jurisprudence. The fee is £15 15s. and intending candidates communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing) only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the University of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: (a) on principles and practice of surgery, clinical and operative surgery, general anatomy, and one optional subject; (b) and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by the candidate, who are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (a) Surgery, special branches; (b) advanced anatomy and physiology; (c) surgical pathology and morbid anatomy; (d) midwifery and gynaecological medicine and surgery; (e) medical jurisprudence and hygiene; (f) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £10 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may, subject to special circumstances, be elected without examination. Women are not admitted to the Fellowship.

LICENCE.—The examination embraces the principles and practice of surgery (including operative surgery and surgery of the ear, throat, and teeth), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee, £15 15s.

Wood Bursary.—The examination for the Wood bursary, of £60 per annum, tenable for three years, will take place on October 21st and 22nd, at the college. The subjects will be found in our advertising columns.

DENTAL DIPLOMA.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established school of dentistry recognized by the College as qualifying for the diploma in surgery. The fee is £10 10s.

Edinburgh Royal Infirmary.—Clinical instruction is afforded at this institution, which contains 780 beds in the building, and 10 beds in a convalescent home under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. It is given in diseases of women, physical diagnosis, diseases of the eye, ear, throat and teeth, and anaesthetics. Separate wards are devoted to venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate tickets amounting to £2 12s. entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointments.

The appointments are as follows —

1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months.

2. Non-resident physicians and surgeons (in the special subjects and for outpatient work) are appointed for six months. These appointments may be renewed.

3. Clerks and dressers are appointed by the surgeons and physicians. These are open to all students and junior physicians holding hospital tickets.

4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1805, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled "The School of Medicine of the Royal Colleges, Edinburgh." The present number of lecturers is about sixty, of whom the greater number deliver qualifying courses of instruction of the same duration and scope as those delivered at the University, while a large number of non-qualifying courses on special subjects of interest to medical science, but which are not required for graduation, are delivered both in the winter and summer sessions at this school. Students attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other qualifications, such as the triple qualification of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow; that of the Royal College of Physicians of London, and the Royal College of Surgeons of England, and the degrees of the other universities. The number of students attending the school averages 1,300 annually.

The minimum cost of the education in the School of Medicine for the triple qualification of the physicians and surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £15, which is payable by yearly instalments during the course of study.

The Winter Session opens October 1st.

GLASGOW EXTRA-MURAL SCHOOL.

St. Mungo’s College and Glasgow Royal Infirmary.—This college was incorporated in 1870, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purpose of the medical school in the grounds of the hospital, and the
laboratories, museums, and lecture rooms are of the most approved description. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the universities and the major medical and surgical colleges in accordance with their regulations.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has 612 beds available for clinical instruction, including an ophthalmic department, and it has special wards for diseases peculiar to women, for veneral diseases, erysipelas, burns, and diseases of the throat. At the dispensary, sportsman and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases—about 78,000 per annum—which in a great industrial centre daily require attendance. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

Appointments.—All appointments are open. There are five physicians' and seven surgeons' assistants, who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons, and there is an assistant to the laboratory, who boards but does not reside in the hospital. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and surgery, and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are valuable to students. In the pathological department assistants are also appointed by the pathologist.

Fees.—The fees for Lectures, including Hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, are £1 1s.

Anderson's College Medical School, Glasgow.—New and excellently equipped buildings were opened in October, 1877, in Dumbarton Road, immediately to the west of the entrance to the Western Infirmary, and within four minutes' walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, practical surgery, and anatomy. There are also provided a library and reading room, and a students' recreation room. The buildings are constructed upon the most approved modern principles. The dissecting room is open in winter from 10 a.m. to 6 p.m., and in summer from 6 a.m. to 6 p.m. These students are assisted in their dissections by the professor and demonstrators, by whom daily examinations and demonstrations on the parts dissected are conducted. The supply of subjects is ample, and students are consequently provided with parts as soon as they may be ready for them. The dissecting room is provided with a complete series of dissecting specimens mounted in plaster of Paris illustrating the anatomy of the human body. There is also a large Bone Room, furnished with complete sets of painted and unpainted bones.

Class Fees.—For each course of lectures (anatomy, ophthalmic medicine and surgery, and surgical, diseases of throat and nose, and mental diseases excepted), first session, £2 2s.; second session (in Anderson's College), £1 1s.; afterwards free. For practical classes (except anatomy), vis., chemistry, botany, zoology, physiology, pharmacy, operative surgery, first session, £2 2s.; second session, £2 2s.

Anatomy Class Fees.—Winter: First session (including practical anatomy), £4 4s.; second session (including practical anatomy), £4 4s.; third session, £4 4s. To complete the necessary courses of practical anatomy, the fee will be £1 1s. Summer: Lectures and practical anatomy, £2 12s. 6d.

Western Infirmary.—Fees: For hospital attendance, first year, £1 10s.; afterwards free. For each clinical class, in winter, £3 3s.; in summer, £2 2s. After three such annual payments of £5 5s. the fee for each clinical class will be £1 1s. Pathology, each course, £3 8s. Vaccination fee, £1 8s.

Royal Infirmary.—Fees: Outpatient practice and clinical instruction, first year, £1 10s.; second year, £1 10s.; afterwards free. Six months, £6 6s.; three months, £4 4s.; pathology, both courses, £6 6s.; vaccination fee, £1 8s.

Dental Curriculum.—Students studying with a view to the dental diploma can obtain instruction in the following subjects: Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, 5, St. Vincent Street, Glasgow.

POST-GRADUATE COURSES IN SCOTLAND.

In Edinburgh a number of post-graduate courses continue more or less throughout the year.

In Glasgow, special courses in ear diseases are held in November and May at Anderson's College, and post-graduate courses in pathology and bacteriology at the University in autumn.

THE OPENING OF THE MEDICAL SCHOOLS.

Charing Cross Hospital Medical School—Thursday, Oct. 1st. Introductory Address by Sir Charles Wyndham.

Dental Hospital of London—Thursday, Oct. 1st.

Guy's Hospital Medical School—Thursday, Oct. 1st.

King's College, London, Medical Faculty—Thursday, Oct. 1st.

London Hospital Medical School—Thursday, Oct. 1st.

Middlesex Hospital Medical College—Thursday, Oct. 1st. Introductory Address by Mr. William Hem, M.R.C.S., p.m.

Royal Free Hospital School of Medicine for Women—Friday, Oct. 4th, and Introductory Address by Miss Pome, M.D., 4 p.m.

St. Bartholomew's Hospital and College—Thursday, Oct. 1st.

St. George's Hospital Medical School—Thursday, Oct. 1st. Introductory Address by Dr. W. R. Dakin, F.R.C.P., at 4 p.m.

St. Mary's Hospital Medical School—Thursday, Oct. 1st.

St. Thomas's Hospital Medical College—Thursday, Oct. 1st.

University College Medical School, London—Monday, Oct. 5th.

Westminster Hospital Medical School—Thursday, Oct. 1st.

PRONUNCIATION.

University of Birmingham—Monday, Oct. 5th.

Cardiff University School of Medicine—Tuesday, Oct. 6th.

Durham University School of Medicine—Thursday, Oct. 1st.

Liverpool University Medical School—Thursday, Oct. 1st. Introductory Address by Sir Dyce Duckworth.

Owens College, Manchester—Thursday, Oct. 1st.

University College, Sheffield—Thursday, Oct. 1st. Introductory Address by Dr. Michael Foster, M.C.B., on Oct. 15th.

The Yorkshire College—Thursday, Oct. 1st.

IRELAND.

Adelaide Medical and Surgical Hospitals, Dublin.

Catholic University Medical School, Dublin—Nov. and Dec.

City of Dublin Hospital—Thursday, Oct. 1st.

St. Vincent's Hospital—Thursday, Oct. 1st.

Queen's College, Belfast—Tuesday, Oct. 26th.

Queen's College, Cork—Monday, Oct. 26th.

Richmond, Whitworth, and Hardwicke Hospitals—Thursday, Oct. 1st.

Royal Colleges of Surgeons in Ireland Schools of Surgery—Thursday, Oct. 1st.

Trinity College School of Physics, Dublin, Dissecting Rooms, &c.—First week in October: Lectures begin first week in November.

SCOTLAND.

Aberdeen University—Tuesday, Oct. 13th.

Dundee University College—Thursday, Oct. 15th.

Edinburgh University—Tuesday, Oct. 13th.

Edinburgh School of Medicine, Rooms and Laboratories—Thursday, Oct. 1st.

Glasgow, Anderson's College Medical School—Thursday, Oct. 15th.

Glasgow, Queen Margaret College of Medicine for Women—Thursday, Oct. 15th.

Glasgow University—Thursday, Oct. 13th.

Glasgow, St. Mungo's College—Thursday, Oct. 15th.

Glasgow Royal Infirmary—Thursday, Oct. 15th.

Royal Colleges, Edinburgh—Tuesday, Oct. 13th.

St. Andrews University—Wednesday, Oct. 15th.

END OF THE EDUCATIONAL NUMBER.
Notes on Current Topics.

Post-Graduate Study.

The possession of a medical degree or diploma by no means implies that the holder thereof has attained the highest pinnacle of knowledge in the temple of Æsculapius, nor is it to be regarded as a signal for the discarding of text-books or the relinquishing of former studious habits. On the contrary, it may be said that a qualification to practise marks the date of the commencement of a higher degree of studentship, which is characterised by a more intimate acquaintance with human nature, both normal and morbid, than has been possible in the earlier days of medical instruction. With the steady advance of specialism it becomes of increasing importance that every medical practitioner who desires to keep fully abreast of the times should cultivate those opportunities which present themselves of obtaining a more thorough grasp and a greater practical knowledge of some branch of medicine or surgery to which he or she may have a natural bent. To rest on one's oars is only to court failure. In order to meet this special need there have arisen various institutions which afford all the facilities required by qualified men and women in this direction. Thus, in London there is the London Post-Graduate Association (formerly known as the Association of the Metropolitan Schools of Medicine), which admits its ticket-holders to the practice of the eleven larger hospitals and certain of the special ones; the Medical Graduates’ College and Polyclinic, which has the advantage of a central position, the West London Post-Graduate College, situated at the West London Hospital, the practice of which is entirely reserved for qualified men; and the North-East London Post-Graduate College at the Tottenham Hospital, to which ladies are also admitted. In Cambridge, Edinburgh, and Belfast facilities are also afforded for medical practitioners to attend courses of instruction in various subjects. Further particulars of these are given elsewhere.

The Evils of the Drug Habit.

The toleration shown by the body towards the very agent which is slowly, yet surely, working for its ultimate destruction is a remarkable fact. In some instances it almost appears in the light of a protective mechanism, while in others it is nothing more than a gradual adaptation of the physical organism to altered conditions of metabolism. The cry for a “pick-me-up,” the demand for a stimulant, in some shape or other, before or after any extra bodily or mental exertion, and the desire for some soothing agent which shall relieve, however temporarily, a distracted mind, are all indications of the unwillingness, real or imaginary, of the generality of mankind—aye, and of woman-kind also—to place reliance in their own powers of endurance. While it is true that every nation possesses its own national drug, it is equally certain that a very large number of individuals cannot refrain from consuming in private various drugs which, if not deserving the name of national at the present time, bid fair to become so unless the eyes of the public are opened to this great evil which lurks in their midst. Men of talent and brilliance whose mental products have pleased and astonished the world, and women around whose fascination and charm has revolved many a distinguished social circle, have fallen alike victims to this insidious and degrading habit. The false idea that better and more original work can be done by means of such an unnatural stimulus has been the ruin of many noble characters. Whether it be cocaine, morphia, antipyrine, phenacetin—the shameful list grows almost daily—each of which has its devotees, the fact remains that the highest mental and moral principles of the drug-habits are slowly undermined and dragged down to the dust. The responsibilities of the medical practitioner in prescribing these potent remedies are, therefore, very considerable, while those of the dispensing chemist are hardly less.

The Drop Method of Giving Ether.

The method of Witzel of administering ether drop by drop has not, in this country, received the attention and trial it deserves. It may be thus briefly described: An hour before the patient is put on the table he is given an injection of morphia, when on the table he is made to count backwards, taking a breath between every two numbers; after he has counted a few numbers, ether is dropped on an ordinary Skinner’s mask till he becomes drowsy, chloroform is then substituted, and as soon as reaction is abolished, ether is again administered. The advantages of the method are very obvious, for it does away with what is always a cumbersome and expensive apparatus, and the administration of an overdose is all but impossible. Most anaesthetists, however, and we think rightly, have an objection to a change of anaesthetic from ether to chloroform during an operation, but we hardly think the administration of chloroform, though doubtless it saves time, an essential part of Witzel’s method. Care should be used to give the ether slowly and regularly, and to avoid all hurry.

The Endowment of Science.

The theme of the Presidential Address at the recent meeting of the British Association is one which must appeal to all thinking persons whatever be their social position and professional avocation. The advance of knowledge in particular professions and callings, and the well-being and ultimate prosperity of the community, are in great measure dependent on adequate instruction in science; yet our educational authorities persist in relegating it to a secondary rank, and the Government, unmindful of its responsibilities in the matter, leave its development to private initiative. Well might Sir Norman Lockyer warn us of the inferiority which must infallibly result from this systematic neglect. The scientific standard required of medical students is, for the most part, absurdly low, yet whenever an attempt is made to
raise it we are met by the objection that in view of the lack of suitable facilities for teaching science any raising of the standard would be followed by inconvenient depletion of the ranks of the profession. Practical science, and science is nothing if not practical, is not to be learned from books. It can only be taught in properly-fitted laboratories, the cost of which is prohibitive for the majority of institutions. Public opinion is gradually awakening to a sense of the importance of the problem, but the State lags behind and cannot be persuaded to undertake a reform which has become gigantic by reason of the apathy of successive Governments.

The New Regulations in the Medical Department of the Navy.

The new regulations have now been issued for the entry of candidates for commissions in the medical department of the Royal Navy. Among the innovations we note that in future rank as staff surgeon will be granted, under conditions, at the expiration of twelve years from the date of entry, provided that the officers have passed the examination five years after their entry in the rank of surgeons. Earlier promotion to staff surgeon rank may be conceded to officers who prior to entry have had charge of a civil hospital of not less than 100 beds, and candidates about to occupy such posts may be allowed to do so without forfeiting their seniority for a period not exceeding one year. New regulations are formulated in regard to the voluntary retirement of officers at the expiration of 4, 5, 10, or 15 years' service. Officers withdrawing after four years will have to serve in the Reserve, but officers so serving who are injured or lose their lives in the discharge of their duty will be accorded the same pecuniary position as officers on the active list. These changes remove several anomalies and grievances, and will no doubt enhance the popularity of the Service.

Bubonic Plague in Marseilles.

An outbreak of bubonic plague is reported to have occurred at Marseilles among the workpeople at a cardboard factory, where a cargo of foreign rags had been transported a few days previously. As usual, the authorities are very reticent on the subject, the deaths being ascribed to pneumonia. Arrangements have, however, been made to isolate the sufferers, and a supply of Yersin's plague serum has been placed at the disposal of the local authorities by the Pasteur Institute. It is confidently asserted that the epidemic has been nipped in the bud, and in such an environment this is a consummation devoutly to be wished.

The Adelaide Coroner and the Skeletons.

The statement that Dr. Ramsay Smith, Coroner of Adelaide, had sent sundry skeletons and skulls to the University of Edinburgh and to the College of Surgeons is not confirmed; but, whether or not, we see nothing in the published reports to imply wrongful action on Dr. Smith's part. In all probability there is a personal element in the raking up of this alleged scandal, but we shall shortly be in possession of the facts elicited at the inquiry which is at present being conducted into the reputed "irregularities."

France.

PARIS, Sept. 13th, 1903.

TREATMENT OF INSOMNIA IN MENTAL DISEASE.

At the meeting of the Congress on Mental Affections M. Trenel passed in review the therapeutic and physical treatment of agitation and sleeplessness in mental diseases. Chloral was the oldest known hypnotic applied to the treatment of nervous affections, but possessed a very depressive action on the circulatory system. Although currently employed in repeated and increased doses, no accident was ever observed, although freely employed in cases of mania, hallucination, &c. Chloral was particularly indicated in delirium tremens. In the insomnia of neurasthenic persons small doses were generally sufficient, but it should be carefully prescribed on account of its depressing effect on the heart. Besides chloral, there existed a number of substances more or less allied to it. Chloralaldehyde, croton chloral, chloralose, chloralanone, chloral amylene (dormol), sulphonal, paraldehyde, Chloralose.—Richet characterised the action of chloralose in certain ways; it resembles chloral, and in others strychnine. He said this on account of the slight exaggeration of the reflexes, trembling and contractions. The sleep produced by chloralose comes on from thirty minutes to three hours after absorption. The dose employed should not exceed ten grains.

Sulphonal, trional.—These agents could provoke in certain persons symptoms of intoxication, yet cases of prolonged employment of these drugs were frequent. The dose of fifteen to thirty grains might be continued three days and then suspended for a few days. Attention should be directed to the kidneys, as those hypnotics were absolutely contraindicated in lesions of those organs. Consequently they should not be employed in aged persons.

Paraldehyde.—The sleep produced by paraldehyde is that which resembles the most normal sleep. It has the advantage, also, of not depressing the heart, nor is it accumulative. It is a good agent, inoffensive, and produces the required effect at the dose of one drachm.

Opium.—Opium or its alkaloids might be used against the state of depression and anxiety which is accompanied by a lowering of the arterial tension. It should be avoided in maniacs and delirium tremens, and reserved for melancholia.

Bromides of Potassium was recommended by the rapidity and the regularity of its sedative action; it did not produce sleep directly, but prepared the system for it. It should consequently be associated with some special hypnotic to produce the maximum effect. Bromides were particularly useful in the treatment of nervous excitement.

[FROM OUR OWN CORRESPONDENT.]

Germany.

Berlin, Sept. 16th, 1903.

In the D. Archiv f. Klin. Med., Dr. Schwenkenbecher has an account of two cases of Labour Paralysis (Neuritis Puerperalis Traumatica).

In both cases there was compression of the nerve fibres of the sciatic plexus. Operative measures, as in both cases recorded, viz., extraction by forceps, were the most frequent cause of the affection. Generally
there was disproportion between the size of the fetal head and the capacity of the pelvis. As a rule there was paralysis in the region of the peroneal nerves. The reason of this is that almost all the peroneal fibres take their origin from the lumbo-sacral trunk, whilst the sacral plexus itself is protected from pressure.

The first case was that of a woman, aged 29, who had suffered from rickets during childhood. The labour was long and examination revealed a contracted pelvis. A dead child was delivered by forceps. Even a few hours after the termination of the labour the patient could not move the right leg. Four months afterwards there was typical paralysis of the right peroneus, and at the same time excessive disturbance of sensibility. A fortnight later the patient was admitted into hospital. The right peroneal muscle showed partial, the right tibialis anticus, and extens. digit. long. complete, reaction of degeneration.

In case 2, that of a woman, aged 23, rheumatic-like pains came on in the pelvis three days after delivery by forceps, the pain radiating into the right leg. There was also disturbance of motility, so that ten days after the confinement the leg could no longer walk. There was then no pain, but burning and numbness in the right knee and foot, and a feeling of great weakness in the right hip. On examination, the right tibialis anticus, the extens. digitorum, and the gluteus maximus showed signs of degeneration. Patellar reflex more active on the left than on the right, the right plantar reflex distinctly stronger than the left.

The prognosis was, that if the condition persisted a year and a half after it had come on. In the second there was improvement. Of thirty-five cases reported in literature the later result was given: four were quite well, twenty-six were not quite well, and one completely paralysed. Upon the whole the prognosis, as in paralysis produced by pressure on the tracheal plexus, was not favourable.

**[FROM OUR OWN CORRESPONDENT.]**

**VIENNA, September 12th, 1903.**

**MYELOMA MUTILPLEX.**

At the "Gesellschaft für Innere Medizin," Jellinek demonstrated Röntgenograms and specimens taken from a patient he showed to the members three weeks prior, who was suffering from extreme anaemia, and who has since died.

In all cases of myeloma all the internal organs, as was expected, were in a healthy or rather normal condition. The bony structure seems to be the centre of disease and change, lymphoid centres being present in almost every bone, which seem to have had their first points in the corpus sterni, whence they spread. This bone seems to have been quite transformed into a neoplasm, and substituted itself for the osseous structure. One rib had a similar change in its structure, while the neighbouring tissues were not free from the influence of the retrogressive metamorphosis. In the spongiosa of the cylindrical bones small yellow centres of myeloma were present.

The most interesting changes, however, were met with in the calvarium, which gave one the impression that it was the covering of a mollusc. The tabuloc vitrea was quite undermined by the diploe, having broken up the surface at different places where these myelomatic centres were present. Here and there were osteoplastic thickenings due to pachymeningitis externa.

The myeloma here had a sort of briny reddish-yellow appearance.

It may be remembered that Jellinek showed this case to the members when alive. The patient was aged 47, and had been taken ill a year ago with pain in their origin for legs associated with rigor. On February 15th, a fall broke the right femur, and on the 20th of the same month the left was broken. All the internal organs were healthy; red corpuscles, 6,050,000; white, 30,000, and globulin, 50 per cent. It was then diagnosed by Jellinek, but Mannaberg thought it might be osteomalacia. Schlesinger also doubted the case, as no paralysis was to be observed.

**Literary Notes and Gossip.**

**DR. T. J. TONKIN continues in the September number of the Empire Review his valuable "Studies on Leprosy in Northern Nigeria."**

**Mr. R. E. MACNAUGHTN contributes an interesting essay on "The Progress of Temperance" to the current number of Macmillan's Magazine.**

In the September issue of the Popular Science Monthly, Dr. Percy G. Stiles discusses the ever-fascinating subject of "Theories of Sleep."

**Dr. Woods Hutchinson, the well-known American pathologist, contributes a suggestive essay on "Play as an Education" to the current number of the Contemporary Review.**

**The current number of Nature contains a short review of Dr. Franz Nissl's remarkable work on the Neurone theory—"Die Neuronenlehre und ihre Anhänger" (Jena: Gustav Fischer).**

**PATHOLOGISTS who are also students of art will be interested in the coloured reproduction of Jacob Jordae's "St. Martin of Tours exercising a demoniac," which appears in the current number of the Studio.**

**In the last issue of the Westminster Review, Mr. H. Rippon-Seymour deals with the recently issued report of the Royal Commission on Physical Training in Scotland; and Mr. J. H. Vines writes on "The Physique of Scottish Children."

**Mr. W. E. Adams, in his "Memoirs of a Social Atom" (London: Hutchinson and Co.), has interesting chapters on "Degeneracy" and "The Decline of Man," which may well be studied to-day, when so much is being said and written concerning physical degradation and psychological decadence.**

**Professor Hamilton and Mr. M'Lachlan Young publish in the current issue of Public Health the result of their recent investigations on "On the Relationship of Human Tuberculosis to that of Bovines," which are in direct contradiction to those alleged to have been obtained by Koch and Schütz.**

**Dr. Arthur Ransome, of Bournemouth, has just issued a new work on "The Principles of 'Open-Air' Treatment of Phthisis and of Sanatorium Construction," which is opportune in its appearance and forms a valuable accompaniment to the important series of articles we are publishing on "British Sanatoria for Consumption."**

**The British Antarctic Expedition is the subject of an important paper by Prof. R. A. Gregory in the September Leisure Hour. It is accompanied by a portrait of the heroic Lieut. Shackleton, who performed great feats of endurance until he was obliged to return home invalided through the bursting of a blood- vessel. A good chart is given of the South Polar regions of previous expeditions.**

It is remarkable to what an extent the illustrated papers seek to portray matters concerning medicine. Should it be considered evidence of a love for the philanthropic or merely an unhealthy interest in the morbid aspects of humanity. The Graphic for September 12th gives a series of photographs illustrating cancer research at the Middlesex Hospital. One of
Obituary.

WILLIAM HENRY CORFIELD, M.A., M.D.

Professor Corfield, who died suddenly in Sweden on August 26th, as already stated, was born at Shrewsbury in 1843, and received his preliminary education at Cheltenham Grammar School. In due course he proceeded to Magdalen College, Oxford, and after a brilliant university career he pursued his medical studies at University College, London, taking his M.B. degree at Oxford in 1868, and M.D. in 1872. He was elected a Fellow of the Royal College of Physicians of London in 1874, having been admitted a Member in 1869. In 1868 he was Examiner for Honours in the Natural Science School at Oxford. He early devoted himself especially to hygiene. He was appointed Professor of Hygiene in University College, his Chair being the first of the kind established in London. He also initiated the first hygienic laboratory. He promoted the foundation of the Parkes Museum, and took a prominent part in organizing the International Congress of Hygiene and Demography held in London in 1891. He was for many years Medical Officer of Health for St. George's, Hanover Square. In 1890 he was appointed Chairman of the H.M. Office of Works. He was also Sanitary Adviser to University College and Hospital. In addition to these public appointments he had a large consulting practice as a sanitary expert.

Dr. Corfield was President of the Epidemiological Society, Past-President of the Society of Medical Officers of Health, and Vice-President of the Sanitary Institute. He was an Honorary Corresponding Member of the Academy of Medicine in Berlin, of the Imperial Society of Medicine, Constantinople, and the Italian Royal Society of Hygiene; he was an Honorary Member of the French Society of Hygiene and of the Hungarian Society of Public Health, and a Fellow of the Medical Society of Sweden.

Among his contributions to medical literature may be mentioned: "A Résumé of the History of Hygiene" (1879); "Essays on Public Health and Utilisation of Sewage" (3rd edition) (1887); "Dwelling Houses; their Sanitary Construction and Arrangements" (of which a fourth edition appeared in 1898); "The Health " (1880); "The Laws of Health" (of which a ninth edition was published in 1896) "Disease and Defective House Sanitation" (1896) (which has been translated into French, Italian, and Hungarian); "The Etiology of Typhoid Fever and its Prevention" (1902); co-author of reports of British Association Sewage Committee (1870-6); "A Treatise on Hygiene and Public Health " (1892).

Dr. Corfield's health had been failing for two or three years. In Professor Corfield we have lost one of the pioneers of preventive medicine and a sanitarian of world-wide repute; the medical profession a very distinguished member, while his numerous friends mourn a genial and highly accomplished gentleman.

THOMAS RICHARD JESSOP, F.R.C.S.

We have to record the death of Mr. T. R. Jessop, which took place on September 6th. In 1856 he joined the Leeds School of Medicine, in 1860 he was appointed house surgeon to the Leeds General Infirmary, and in 1870 he was elected Surgeon to the Leeds General Infirmary. For twenty years he served on the full staff of that institution, and it was there that his great reputation was built up. He is credited with the first operation for abdominal pregnancy, due to secondary intra-peritoneal rupture of the gestation sac, in which the lives of both mother and child were saved. It was he who first, in England, successfully removed a sarcoma of the kidney in 1877, and as an operator for stone he had experience beyond that of most English surgeons. In the year 1893 he was appointed Consulting Surgeon to the Infirmary, and on the amalgamation of the school with the Yorkshire College he was the first Professor of Surgery. For eleven years he was a member of the Council of the Medical College of Surgeons of England, and he was appointed Senior Vice-President, and Bradford Lecturer. For many years Mr. Jessop had probably the largest practice of any surgeon in the North of England.

As a lecturer he was highly popular. Though no orator, his language was clear and to the point, and the surgical axioms he laid down remained deeply impressed on his listeners' minds. The students learned from him, for he took upon himself as their friend as well as teacher, for while demanding from them the best work they could produce, he ever considered their personal welfare and showed an interest in their progress. In diagnosis he was both brilliant and accurate.

Mr. Jessop was essentially a great man and a good man. Prudent, deliberate, and perspicacious, he had nevertheless a charitable heart, and succeeded in endearing himself to all with whom he came into contact.

Medical News.

Suicide of a Walsall Practitioner.

MR. ADAM GARTLEY MERSON, L.R.C.P., L.R.C.S.Ed., of Walsall, committed suicide last week by hanging himself. He had for some time been in indifferent health, and was only 52 years of age.

Sudden Death.

DR. LUIS P. WALTON, aged 56, of New York, died suddenly at the Bath Club, London, last week after taking a bath. At the autopsy the heart was found to be greatly enlarged and death was attributed to cardiac failure.

The Franchise of the Royal College of Surgeons.

The Council of the Royal College of Surgeons of England have decided not to enter an appeal against the decision of the Reviving Barrister withholding the franchise from certain members of that body who claimed that right in virtue of ancient charters.

Diseased Emigrants.

It is stated by the New York correspondent of the Liverpool Journal of Commerce that owing to the difficulties in connection with the refusal to the treaty of "Provisions and Utility of Sewage" (3rd edition) (1887) "Dwelling Houses; their Sanitary Construction and Arrangements" (of which a fourth edition appeared in 1898) "The Health " (1880) "The Laws of Health" (of which a fifth edition was published in 1896) "Disease and Defective House Sanitation" (1896) (which has been translated into French, Italian, and Hungarian) "The Etiology of Typhoid Fever and its Prevention" (1902); co-author of reports of
NOTICES TO CORRESPONDENTS.

Vacancies.

Birmingham Workhouse Infirmary.—Assistant Resident Medical Officer and Assistant Resident Surgical Officer, Salary £350 per annum, for each office, with furnished apartments, rations (which do not include alcoholic liquors, tea, laundry, and attendances). Applications to Walter Bowen, Clerk to the Guardians, Edmund Street, Birmingham.

Burton-on-Trent Infirmary.—House Surgeon. Salary £250 per annum, together with furnished rooms, board, and light fare. Applications to the Hon. Secretary, Wood Street, Burton-on-Trent, or Dr. W. A. W. George, Royal Victoria Hospital—House Surgeon. Salary £400 a year with board, lodging, and washing. Applications to Hon. Secretary, Arthur E. Ewing, Eton, St. George’s Street, Dover.

Eccles and Patricroft Hospital.—House Surgeon. Salary £70 per annum, with board and washing. Applications to Hon. Sec.

Metropolitan Asylums Board.—Visiting (daily) Medical Attendant at Rochester House, Little Ealing, W. Salary of £100 per annum. The institution accommodates 150 improvable imbecile children. Applications must be made on forms obtainable from the Clerk, Metropolitan Asylums Board, Thames Embankment, E.C.

Stround General Hospital.—House Surgeon. Salary £300 or remittance, with board, lodging, and washing. Applications to the Hon. Secretary at the Hospital, Streatham, Glo.

Three Counties Asylum, near Hitchin.—Junior Assistant Medical Officer. Salary £100 a year, with board lodging, and washing. Applications to the Medical Superintendent, Wansdworth and Clapham Union Infirmary, St. John’s Hill, near Clapham Junction, for Assistant Medical Officer. Salary £175 per annum, with board and washing. Applications to the Medical Superintendent.

Deaths.

CROCKETT-BROWN.—On Sept. 8th at Blackheath, Belgravia, Emily wife of Sir James Crockett-Brown, M.D., LL.D., F.R.S.

Dow.—On September 9th, at 2, St. John’s Wood, Caroline—all, the result of an accident, Thomas Anthony Dood, L.R.C.P., M.R.C.S.

PADWICK.—On September 4th at Holyoake, John George Fadwick, second son of the late Thomas Fadwick, Station Road, Redhill, aged 30 years.

RUBE.—On September 11th, at 15, St. Stephen’s Road, W., Georgina R., widow of Malcolm R., Deputy Inspector General of Hospitals, Bengal Medical Service, aged 68 years.

OPERATIONS.—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew’s (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas’s (2 p.m.), London (2 p.m.), King’s College (5 p.m.), St. George’s (2 p.m.), St. Mary’s (2 p.m.), National Orthopedic (10 a.m.), St. Peter’s (12 noon), Samaritan (3.30 p.m. and 3.30 p.m.), St. Ormond Street (1.30 p.m.), St. Northern Central (1.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (10 a.m.), Cancer and Throat, Great Northern Central (1.30 p.m.), London (2.30 p.m.), St. Mary’s (1.30 p.m.), St. Peter’s (12 noon), Samaritan (1.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Soho Square (2 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (10 a.m.), St. Mary’s (2 p.m.), Samaritan (3.30 p.m. and 2.30 p.m.), Throat, soho Square (2 p.m.), Guy’s (1.30 p.m.),

THE MANAGEMENT OF PREGNANCY COMPlicated BY UTERINE FIBROIDS. (a)

By AMAND ROUTH, M.D., B.S., F.R.C.P.Lond.,
Obstetric Physician to Charing Cross Hospital; Consulting Physician to the Samaritan Free Hospital for Women and Children; Examiner in Obstetric Medicine to the Society of London and University of Birmingham; Examiner in Midwifery and Diseases of Women at Royal College of Physicians of London (Conjoint Board), &c., &c.

After a short introduction the danger of the complication during both pregnancy, labour, and the puerperium is discussed, and it is shown that since anaesthetics and antiseptics have been introduced, and modern surgical methods adopted, the maternal mortality has been diminished from 50 per cent. to 3 per cent., and infantile mortality from 70 per cent. to 23 per cent.

The subject is discussed under two heads:
(1) The influence exerted by pregnancy upon the fibroids, and (ii.) by fibroids upon the pregnancy; (2) the treatment indicated.

1. (i.) The effect of pregnancy upon the fibroids.—It is doubted whether individual fibroids rapidly enlarge during pregnancy, and also whether atrophy takes place during involution as constantly as is usually stated. The tendency to softening and degeneration of the fibroids, and the danger arising from this, especially as regards readiness to become infected during the puerperium, is dwelt on, as well as the tendency of the fibroid to become more pedunculated, and, if submucous, to become entirely extruded and necrotic.

(ii.) Effect of fibroids upon the pregnancy.—It is endeavoured to be shown that sterility is not very often caused by fibroids, and, if present, that it is not the direct result of the fibroid, but rather due to changes in the endometrium and to altered relation of tube and ovary. It is further shown that abortion is not often induced by fibroids, unless they are submucous. Statistics show that abortions have about the normal percentage. Fetal malpresentations of all varieties are shown to be commonly increased, but cases of placenta praevia are not more numerous. Uterine inertia is not a usual phenomenon, but irregular action of the uterine muscle fibres leads to delayed labour, even if no obstruction be present. Post-partum haemorrhage is more frequent, both from pathological and physiological causes. Obstruction to the birth of the child is shown to frequently threaten, but to be remarkably and almost consistently absent at labour, owing to spontaneous elimination of the pelvic fibroids, often during the last few weeks of pregnancy, and even during the second stage of labour. Sepsis, with secondary infection of the fibroids, is shown to be a great danger in the puerperium.

2. Treatment.—Before uterine viability: An expectant treatment is the best, unless there are urgent present symptoms, or unless incomplete abortion or sepsis occurs. Where a pelvic fibroid is present, gentle attempts may be made to replace it. Induction of abortion should be definitely abandoned. If pressure symptoms supervene, myomectomy becomes the ideal operation for subserous fibroids, and failing that, hysterectomy may be required. The relative value of, and the indications for, the two operations are discussed. After uterine viability: As a temporary expedient, reposition of an obstructing fibroid may be tried, leaving the treatment of the fibroid to be dealt with later. The danger to the mother of delivering a child by forcps, version, or embryotomy is shown to be very great. If a cervical fibroid be present, it may be dealt with by vaginal enucleation as an alternative to hysterectomy. In all other cases of obstructing fibroid, abdominal section is required, and as a first step the child must be delivered by Caesarean section.

Subsequent alternative procedures may be then adopted, and may be enumerated as follows:—
1. Caesarean section alone.—The uterine wound may be closed and the fibroids dealt with at a later date if need be. This would very rarely be the right treatment.
2. Sterilisation of the patient by ophorectomy, with the hope that atrophy of the fibroids would follow. This would now rarely be considered a satisfactory operation, especially if the fibroids were in the lower uterine segment.
3. Myomectomy.—Sometimes this operation is indicated, but should always be preceded by Caesarean section.
4. Abdominal hysterectomy.—Different procedures and statistics are reviewed, and preference given to the supra-vaginal operation with retro-peritoneal treatment of the stump by Baer's or Czerny's methods, and to panhysterectomy which by Doyen's method is not much more difficult; and the special cases in which panhysterectomy would be indicated are where cervical fibroids are present, and in cases of sepsis.

In both operations one ovary at least, if healthy, should be left in situ. Two successful cases of supra-vaginal hysterectomy for pelvic fibroids with retro-peritoneal treatment of the stump in the author's practice are given. Lists of all operations of supra-vaginal hysterectomies and retro-
peritoneal treatment of the stump, and of pan-
hysterectomy, are given.

The treatment of cases where labour has oc-
curred in fibroid uterus is then considered, and it is
shown that if the fibroids become infected from
uterine sepsis, a prompt panhysterectomy may
become necessary to save the patient's life.

THE UTILISATION OF INFANTS' MILK DEPÔTS. (a)

By Dr. T. D. LISTER, M.D., M.R.C.P.,
Assistant Physician to the Royal Hospital for Women and Children.

The problem of infant feeding is so many-
sided that it is with great diffidence that I venture
to bring any question relative to it before you.
My only excuse must be the fact that a movement
is going on of which the ultimate extent is at
present not to be estimated, but that its develop-
ment will be rapid and widespread seems almost
certain. It is the movement in the direction of the
general establishment of milk depôts for infant feeding.

This question involves a matter of direct in-
terest to those who have to practise among the
children for whom these depôts are primarily
intended.

Those who have to treat the children of very
poor and very ignorant parents, or the children
of mothers whose employment necessitates a
considerable amount of child neglect, have to face
continually certain difficulties which infants' milk depôts are designed to overcome. For the
wealthier classes no such difficulty exists.

When the mother is able and willing to feed
her child herself these difficulties of treatment are
minimised, for natural feeding and maternal care
are the normal preventives of infantile mortality.
But it is impossible to be blind to the fact that
hand-fed infants form an increasing proportion
of the whole infant population. The chief diffi-
culties met with in feeding such children among the
poor arise from ignorance and lack of facilities
for the proper preparation of food, perhaps also
from prejudice and perversity at times. Broadly
speaking, as we all know, they are associated with
the use of copper bottles, contaminated milk
and milk substitutes.

We are, as a profession, agreed that cow's milk becomes the only practicable basis for infant
feeding, that it should be pure and fresh, and not
over-treated either chemically or by cooking,
and that the simpler the bottle and teat, the
better.

I do not know what method of meeting these
requirements on a large scale can be devised
better than this system of infants' milk depôts.
It is recognised by public health authorities that
such a system eliminates all the many dangers
arising from contamination by carelessness, either
in transit or at home, both of which, and especially
the latter, have been proved to be fertile causes of
infant mortality, and that it prevents the use of
many of the abominable milk substitutes that one
constantly sees in the infants' dietary. Moreover,
it has already been successful in those towns in
this country where it has been tried, and there is
a very large experience of its success abroad.

No system of diminished impurity of the fresh

(a) Read in the Section of Diseases of Children, British Medical
Association, Swansea, July 30th, 1903.

milk supply will get over the difficulties of home
contamination and carelessness, and the use of
milk substitutes among a certain class. The
"depôt" seems to be the practical method.
It has been pointed out in the Journal that
an extension of the system on a large scale
seems likely to occur. This is particularly
imminent in those centres of population where
there exists a crowded poor class having a high
infantile mortality. High infantile mortality is
an index to some extent of the health of the
child community, and, in my opinion, measures
to reduce it are a necessary preliminary to the
improvement of our national physique. You cannot
make strong men and women out of stunted
infants. A proper system of infants' milk depôts
will go a long way to help in the proper nourish-
ment of a certain class of infants.

This is a matter which, I think, deserves our
attention in this Section, for the future relation of
the profession to these depôts is a question of
great importance. There are certain objections
to leaving the matter entirely in the hands of
either public or private individuals other than
medical practitioners.

It has been pointed out, notably by Dr. Peyroux,
that there is a danger of the encouragement of
hand feeding, at the cost of maternal responsiblity,
under the usual conditions of management of the
depôts.

What I wish to bring before you is, that it is
our duty to lend all our influence and assistance in
counteracting this, as well as other dangers, in
the use of such depôts. To say that any system
of hand feeding of children, whether "percentage"
and other so-called scientific methods, or the
simpler methods used in milk depôts, is as good
as natural feeding is to be a contributory to child
slaughter. Prof. Rotch, who is probably the best
living authority on the cow's milk feeding of chil-
dren, himself said, in this Section last year, that
no method yet devised is equal to that of Nature.

Other objections have been raised from time to
time to the establishment of infants' milk depôts,
as, for instance, that the method of feeding is not
an ideal one. I do not think we need worry
about that when the most scientific methods are
practised by their authors not to mention
Infantile mortality and its accompanying limiting of
the infantile population, so far as they may
be diminished by careful feeding, are matters
requiring our immediate attention. The method
of milk depôts has been proved in practice to
bring the mortality of children fed in them down
to what has been estimated to be the minimum
mortality of children under one year old. It has
attained this maximum success though it has had
to contend with the danger arising from its therapeu-
tic use in infantile disease, and has not yet
been very largely used for its more legitimate
purpose as a substitute for bad hand feeding. A
more important objection is the loose way in
which milk has sometimes been distributed by
these depôts without the accurate observation
of the infants and a knowledge of their require-
ments which systematic medical advice and
supervision alone could give.

I will not enter into the political question
involved in municipal enterprise establishing
milk depôts. That is a matter which, if it be
medical at all, is one for the Section of State
Medicine. As members of a profession to whom
a certain amount of responsibility attaches in regard to this matter of infant feeding, our desire should be to remove the difficulties in the way of careful feeding among the very poor and ignorant; and if milk depôts offer, as they seem to do, the practical solution of these difficulties, we need not mind who furnishes them. We must remember that a milk supply is a matter coming under the public health authorities and that whoever furnishes milk depôts, their sanitary control must remain with these bodies. But the haphazard use of milk depôts by all and sundry members of the population should be unhesitatingly condemned by us. The infants fed in them should be under medical advice and observation. There is little doubt that the usefulness of this system has been to some extent minimised by the absence of this factor, for had they been in all cases established with the co-operation of practising members of the profession, their usefulness would have been enormously extended among the class for whom they are most urgently necessary, and many of the objections raised to them would have been eliminated.

How is this medical supervision of the infants to be secured without affecting the control of the depôt by the health authorities, and how is it to secure milk depôts where they are most wanted?

Obviously only by the co-operation of the various interests, and it is for this co-operation that I think we should work.

The plan which has been adopted in Lambeth has already led to a satisfactory development so far as that district is concerned. At a meeting of the Medical Committee of my hospital, resolutions were adopted approving of the principle of infants' milk depôts, and pledging the staff to do what they could to induce patients to use such a depôt if it were established by the Borough Council near the hospital. This attitude was approved by the Committee of Management, and communicaed to the Lambeth Borough Council in the form of a petition. Dr. Priestley, the medical officer of health, then obtained similar promises of support from St. Thomas's Hospital and the York Road Lying-in Hospital, which are both close to the Waterloo Road Children's Hospital. With these pledges of support from institutions dealing with a very large number of necessitous infants, the success of a depôt in the immediate neighbourhood is already assured.

This course may readily be followed up in some of the more crowded and poorer districts of Lambeth by pledges of support from the local medical societies, or any branch of the British Medical Association, the members promising that they will encourage their poorer patients to use a special infants' milk depôt when hand feeding is necessary.

As I have said, it does not matter to us, as a profession, where the funds come from to furnish the depôts. That is a matter for local option. There is no doubt that the action of the Local Government Board in disallowing the expenses of the Battersea milk depôts will soon lead to a clear decision as to the power of district councils in this matter; but where the district councils do not care to undertake the work I think there is no reason why, having obtained the support of the medical profession in the district, it should not afford information and facilities to charitable bodies on the one hand, or contractors on the other hand, to enable them to carry out this necessary work in the districts where it will be most useful. As a mere matter of personal opinion, I believe this to be so important a branch of preventive medicine that, properly guarded against abuse by the co-operation of medical practitioners, it should be undertaken by the municipal authorities. That such depôts would be also of great advantage to us as practitioners in securing a definite method of feeding infants under one year of age carefully and exactly, is undeniable with the class for whom we want it.

I have, therefore, brought the matter before you as a broad suggestion of the way in which this question may be approached.

All I can claim for the suggestion is that such a method of co-operation would largely remove the objections that have been raised to the establishment and use of infants' depôts by showing that the infants fed in them were under medical supervision, and that they were believed to be necessary and useful by the medical men in the districts where similar resolutions to those I have mentioned are adopted.

It is a confusion of interests which prevents this work being done, and it is a co-ordination of interests which seems to me, as far as medical interests alone are concerned, likely to help towards its accomplishment.

LECTURE ON PRIMARY MALIGNANT INTRA-THORACIC TUMOURS (a).
By T. N. KELYACK, M.D., M.R.C.P., Assistant Physician, Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood, London.

It may be suggested that the study of primary malignant disease of intra-thoracic structures is likely to prove a barren and profitless pursuit, and I cannot deny that as regards that causation pathological features and treatment, there is nothing of startling novelty to be presented. Nevertheless, I venture to think that by neglecting to turn the sod, even of such a seemingly unproductive field, we may be in danger of forgetting not only the magnitude of our ignorance, but even such factors as contain elements of usefulness.

At the present time, when the sanatorium treatment of pulmonary tuberculosis and certain other forms of chest disease is fashionable, both with the profession and the public, and when, moreover, it is particularly desirable on every ground that an accurate diagnosis should be made at the first possible stage in the development of all such morbid conditions, it seems to me very essential that no pains should be spared in correcting, modifying, amplifying and verifying our present methods. Nowadays almost every practitioner is called upon to express an opinion as to the serviceability of sanatorium treatment in the management of many cases of chronic and progressive disease of the chest, and a serious responsibility is thus being added to the already heavy burden of the medical adviser. It is partly on account of this that the search for new methods, for the sake of medical science, and in the interest of the patients themselves, and, at least in many instances, also on financial and personal grounds, great care should be exercised in the selection of cases for what must oftentimes be expensive institutional or climatic treatment.

As I shall have to show presently, the early recognition of the various forms of intra-thoracic growth
is often fraught with much difficulty and surrounded by peculiar perplexity. Certainly, mistaken diagnoses are common, or, at all events, a correct aspect of the case is often not arrived at until much useless trouble and expense have been incurred, with no comfort to the patient and but little kudos, I am afraid, for my medical adviser. It is manifest, therefore, that it is particularly desirable that we should be alive to the importance of correctly interpreting the facts which indicate the various stages of the growth at an early time. I have selected as the subject of our discussion primary malignant intra-thoracic tumours. In the time at our disposal I do not propose to detail to you the very interesting chapter on pathology which records the unfolding of knowledge in regard to this class of neoplasms. Those of you who wish to follow the matter further will find many useful references in the readily accessible writings of J. Cockle (1), Wilson Fox (2), H. A. Hare (3), F. T. Roberts (4), and J. L. Steven (5).

My main object is rather to focus our present knowledge on the subject, and by a concise presentation of now fairly established pathological data, furnish material which will, I hope, prove of directing value in actual clinical work.

In considering the practical bearings of our study it is necessary to have definite ideas respecting the pathology of the various growths of the chest, and a clear remembrance of the anatomical relationships of the mediastinum and its contents and the other intra-thoracic structures. I propose, therefore, to deal first with the chief pathological features of malignant intra-thoracic disease considered as a whole, and, secondly, the more important characteristics of (1) mediastinal; (2) pulmonary; and (3) pleural growths.

And in following such a course one is guided by utility as well as necessity, for there is often much difficulty clinically in distinguishing accurately between mediastinal and other intra-thoracic growths, and as a post-mortem it is by no means always easy to decide where a tumour originated.

ETIOLOGY.

The confusion which has persisted in regard to the nomenclature of tumour formations, and which, indeed, has even still not altogether passed, makes it almost impossible to array sufficient data for the formation of a reliable statement regarding the various factors in the etiology of intra-thoracic tumours. The following points, however, seem to be more or less definitely ascertained:—

Sex.—There is no marked sexual influence apparent, although when all recorded cases are taken the male seems somewhat more frequently affected than the female.

Age.—Sarcoma may occur at any period of life, in early childhood or advanced life. Carcinomata are practically limited to middle life and advanced years. When all forms of intra-thoracic tumours are considered together, irrespective of their actual pathological form, it would appear that the most likely period for their development lies between thirty and fifty. Inheriitance is said to have an influence in determining intra-thoracic neoplastic development, but it is not usually a conspicuous factor.

Injury, either from blows or long-continued pressure, as in certain occupations, has been alleged to be of etiological importance, but of this there is much doubt. Infection.—Some pathologists look upon certain forms of mediastinal tumour as dependent on infective agency, but while there is some evidence in favour of this view it is at present far from being substantiated.

We have to conclude that the causation of primary intra-thoracic malignant diseases till remains wrapped in mystery which surrounds the origin of most forms of progressive tumour formation; and generally no probable or likely causes can be ascertained.

SEAT OF ORIGIN.

Malignant disease may arise in connection with almost any of the thoracic contents:—(a) The glands, bronchial and mediastinal, undoubtedly form the most frequent seat for the origin of sarcomatous growths. (b) The connective tissue and fat of the mediastinum may also afford the originating structures. (c) The lung is occasionally the seat of primary tumours. (d) The pleura and subpleural tissues are exceptionally affected. (e) The pericardium and subpericardial tissues are only very rarely the seat of primary growth. (f) The oesophagus is, as is well known, a common seat of epithelioma, and from thence there may sometimes be conspicuous extension into the mediastinum. (g) Primary growths of the trachea and main bronchi are rare, but occasionally occur. (h) Tumours in connection with the bronchial tree are occasional. (i) The remains of the thymus are said to afford a basis for some forms of growth. (j) Tumours of the thyroid may also very occasionally extend into the mediastinum. (k) It has also been suggested that growths might arise in connection with the adventitia of vessels, but of this there is probably no altogether satisfactory evidence. (l) The structures of the thoracic wall, particularly the periosteum of the sternum and ribs, may in some instances be primarily involved.

As we are not at the present time considering secondary growths of the thorax there is no need here to dwell on the relative frequency of the parts in which such may be met with.

NATURE OF GROWTH.

We are to-day dealing solely with the primary malignant tumours of the chest. I shall not, therefore, trouble you with the references to the rare and comparatively unimportant forms of simple or so-called non-malignant or benign intra-thoracic tumours, which have from time to time been described, such as fibroma and fibro-plastic growths; lipoma or lipomata, chordromata, osteo-chordroma, and enchondroma, &c. And I do not intend to deal with the intra-thoracic glandular involvement, which is best considered as a part of Hodgkin's disease.

Limiting ourselves in the manner indicated we can say at once that the tumours under consideration fall into two great classes:—(1) The sarcoma; and (2) the carcinomata. In almost every case of clinical importance the intra-thoracic growth will be found either to be a sarcoma or a carcinomata. The former is undoubtedly the most frequent form of tumour of the chest, and practically all those arising in connection with mediastinal structures are of this nature; while carcinomata in the lung are usually considered to be of a carcinomatous character. It is true of recent years evidences have not been wanting to show that lines of sharp demarcation in our grouping of tumour formations are not always in accordance with scientific principles, but for practical purposes we may continue to arrange the greater number of the intra-thoracic growths into one or other of the two classes I have indicated.

GENERAL CHARACTERS.

The general characters of these growths need only be briefly touched upon at this point. The sarcomata, generally speaking, tend to assume an infiltrating form, while in many cases at least, and in their early stages, carcinomata, especially when occurring, as is usually the case, in the lung, are often localised.

Intra-thoracic growths show considerable variation in size and extent, consistency, rapidity of development, invading tendencies, and situation and direction of extension, depending apparently in great measure on the precise character and arrangement of the cells constituting the tumour.

In some quickly-growing sarcomata the mass is made up almost entirely of soft, rapidly proliferating cells which often show a marked tendency to soften and readily break down; while in other slowly-progressing cases the origin of the tumour is from more elaborately evolved cells. In many of the mediastinal sarcomata the lymphoid structure is abundant.

It is interesting to note here that while, generally speaking, intra-thoracic growths tend to cause bulging
the case, the other may undergo compensatory enlargement. Distinct emphysema occasionally develops. (f) The lung may also be the seat of extensive passive congestion, and marked oedema and even haemorrhage may result.

5. I have already referred to the importance of the involvement of the blood-vessels and nerves.

6. It is well also to remember that in many instances pleural effusion occurs, sero-sanguinous or actively hemorrhagic in character.

7. Pericardial effusion is occasionally met with.

8. Not only are the intra-thoracic structures infiltrated, but in many instances actual displacement occurs; this is of particular importance, of course, where the heart is concerned.

9. And before leaving the consideration of these secondary conditions, I must remind you that those of an inflammatory nature may give rise to distinct pyrexia.

The bearing of all these pathological features on the clinical investigation of the case is, of course, quite evident.

SECONDARY CHANGES.

In assisting us also to understand the course and variation in clinical cases, it is well to remember the chief changes which the tumour itself may undergo. In not a few instances extensive necrosis occurs. In the lung especially distinct cavitation may thereby result. By the softening and breaking down of a growth and its communication with a bronchus portions of growth may sometimes be expectorated.

SPECIAl TUMOURS.

And now in the few remaining minutes at our disposal I wish very briefly and as concisely as possible to put before you some few points in connection with: (i.) Mediastinal tumours; (ii.) pulmonary tumours; and (iii.) pleural tumours. The lung in connection with these three regions may be conveniently distinguished and separated both pathologically and clinically, for they present fairly well-defined characteristics.

MEDIASTINAL GROWTHS.

The majority of these are, as I have already indicated, of a sarcomatous nature. Occasionally, however, carcinomatous masses are met with in the posterior mediastinum, when probably they have originated from the epithelial structures of the oesophagus, bronchi or trachea. It is held by many that the majority of growths originate in the anterior mediastinum. The bearing of this on a careful clinical search for physical signs is evident.

TUMOURS OF THE LUNG.

Primary growths of the lung are decidedly rare, and are usually considered to be of a carcinomatous nature. They appear to arise in connection either with the lining epithelium of (a) the bronchi, or (b) the alveoli. In appearance they usually form soft, nodular, white or pinkish-white masses, of variable size, infiltrating adjacent structures and giving rise to secondary deposits in lymphatics and bronchial glands. As already indicated, they may soften and so give rise to distinct pulmonary excavation.

TUMOURS OF THE PLEURA.

Regarding the malignant growths arising in the pleura, I must only stay to remind you that they are generally considered as members of the so-called endotheliomatous class of growth. They usually occur as diffuse, white, fibrous indurations with scattered nodose swellings.

I have insisted, at what I fear you will consider a wearisome length, on the importance of the pathological features of these intrathoracic growths, and it is only by a clear recognition of the morbid characters of the tumours and the precise nature of the pathological conditions arising from or associated with their development that we can expect to satisfactorily master the intricacies of their clinical investigation. In our next lecture I shall hope to point out the bearing of the pathological facts we have put to you to-day on the symptomatology and diagnosis of intra-thoracic growths.
the liver was found to be rather larger than normal, and slightly tender to pressure. No shivering motion was complained of. Upon these data a consultation was held, and the diagnosis of catarrhal jaundice in a pregnant woman was arrived at. Towards the close of the eight month of pregnancy (February 18th, 1902, at 8 p.m.), the pains of labour began, with the escape of blood-stained mucus from the genitals. As the strength of the patient was obviously waning, on the morning of the 19th, at 5 o'clock, I was asked by the husband to examine the patient, and on doing so I found her in the stage of expulsion, with the fetus in complete right position. In the course of half an hour delivery took place spontaneously, with the fetus in a state of stasis, but it soon after recovered. On closer inspection it did not show the least trace of yellow colour. The afterbirth, entire and sound, was expelled spontaneously ten minutes after the fetus was born. It was carefully examined and showed a distinct greenish-yellow coloration on its uterine surface. The puerperal period ran a normal course without thermometric disturbance, the yellow coloration disappeared little by little, and after about a month the patient's health was completely restored.

II. On the evening of July 21st, 1902, I was summoned by a midwife to assist a woman suffering from post-partum hemorrhage. The uterus was in a state of uterine inertia half an hour after the fetus had been delivered. I hastened thither, and by squeezing the uterus, provoked the separation and expulsion of the placenta. I obtained complete hemostasis. The hemorrhage having been arrested, I questioned the patient and elicited the following information:—It was her second labour, and she was twenty years old. Fourteen days after the last menstrual discharge had taken place on October 21st, 1901. Up to the fourth month pregnancy was accompanied by nausea and vomiting. Parturition was expected to take place on July 21st, and this proved to be correct. On examination, she showed a distinct yellow coloration of the skin and of the visible mucous membranes. Normal temperature and pulse. In the abdomen there were to be noticed slight meteorism, no contracted uteri, and the fundus reaching the umbilicus. The slightly enlarged liver, tender on pressure. Nothing worthy of note in respect of the thoracic organs. The patient had always been in good health. She had never suffered from malaria. In the fourteenth year of age she had an attack of typhoid fever and was completely cured of it in about a month. On the seventh month of the last pregnancy, without indulging in irritating food, she began to suffer from gastric disturbances, nausea and mucous bilious vomiting. Later on these disturbances were associated with slight pain in the right hypochondrium, a pain that grew worse under pressure or on movement. The urine, withdrawn by the aid of a catheter, was turbid with yellow froth; sp. gr. 1021; presence of biliary pigments, neither albumin nor sugar. From the ensemble of the objective examination a diagnosis of catarrhal jaundice in a pregnant woman became the more probable. On the evening of August 8th and eight month was arrived at. She was put on a milk diet and ordered purgatives and enemata in order to overcome the obstinate constipation. In the meantime pregnancy reached its term, and on the evening of September 10th the patient left her bed for the first time in a good state of health.

Jaundice in association with pregnancy is well known to be of comparatively common occurrence, for in this
state special causes occur to produce it, over and above the many ordinary ones. Thus the gravid uterus may exert pressure on the liver, and consequently a flowing of the biliary secretion. Pregnancy itself favours the stasis of bile by the fact, well demonstrable by Huch, that the biliary pigments in bile, while moving in its movements, and is therefore unable to assist in emptying the gall-bladder. As is well known, this last occurs in women leading a sedentary life as well as those who follow the exploratory profession of wearing very tight corsets. Diseases of the biliary canals causing jaundice in pregnant women are therefore of common occurrence, and some observers have noted that pregnancy renders the prognosis of icterus even on account of its pre-existing renal and hepatic changes. Whilst, however, numerous observations are on record of the various kinds of jaundice in pregnant women, those bearing on the condition of the fetus, i.e., whether or not it is born with the icteric tint, are conspicuously rare.

Freireich relates only three cases in his classical book, "Maladies du Foie," and all with premature delivery, in which the fetus was born jaundiced, and affected by disease of the liver with serious jaundice did not exhibit any yellow colour when born. Herf, in the "Encyclopedia," and Müller, in his "Treatise," draw attention to the fact that the fetus is seldom born jaundiced, except in cases in which the foetal movements were temporarily arrested.

Many distinguished obstetricians have recorded cases of jaundice during pregnancy, but whether in these cases the fetus was born jaundiced no mention has been made, and I must presume that the product of conception must never have been born yellow-coloured, for such a fact would not have escaped the notice of the most superficial observer. So far as I am aware, the only noteworthy observation on the subject is that published under the title, "Investigations on Acute Yellow Atrophy in Pregnant Women," by Dr. Fabio Vitali, assistant professor of medical science under Professor A. Murri. He studied the case which chanced to come under his notice with much interest, and by carefully examining the anatomical and histological alterations of the various organs of the mother and fetus, he was able to arrive at very valuable conclusions. So far as concerns this work of mine, I found that the five-months' fetus was yellow-tinted, but, from the microscopic investigations carried out by Vitali himself, it ensues that both in the maternal organs as well as in the foetal ones identical changes were registered in so far as concerned the hepatic cell. We are led to infer, therefore, that the biliary pigments do not pass from the maternal blood into that of the fetus, but in their stead the poisonous substances was absorbed and cause the same alteration—i.e., acute yellow atrophy. Thus it is easily explained why the fetus assumes the yellow tint, and why these cases that determine the same change in the mother’s liver, as in that of the foetus readily occur in diseases of infective origin. Equally well known is that special form of jaundice of the newborn, rather frequently met with when the infant is affected with either biliary lithiasis, hepatic syphilis, and toma’s weight—was the test of the excretion process of the biliary canals, or umbilical phlebitis or perihelitis. Whereas, if we consider the simple question—viz., whether it is possible for the jaundiced mother to pass the yellow coloration without this being dependent on some of the above-mentioned morbid changes in the liver of the fetus, it appears to me to be very difficult. As this fact of the non-transmissibility of biliary pigments to the fetus, as latterly reported by me, appeared worthy of consideration, I decided to experimentally test the resistance of the placenta to the passage of biliary pigments, a study which from this point of view I believe to be so far quite original.

I will first of all give the results of the examinations of the two human placenta, before dealing with experiments on pregnant animals. In carrying out these investigations I proceeded as follows:

First Placenta.—After cutting off the membranes on the circumference of the placenta and the umbilical cord close to its placental insertion, and having removed the small bloody clots existing on the uterine surface of the placenta, this was washed with distilled water; the two placentae were then dried, and then, by means of a beer mincer, triturated and reduced to a pulp. Then it was digested in alcohol for forty-eight hours, filtered and subjected to pressure. The alcohol was evaporated over a water-bath, the residue washed in water and again filtered. Some nitrous acid was put into a test-tube, and a small quantity of the filtered aqueous residue slowly run over the liquid layer, and thus at the point of contact of the two liquids a disc was obtained that, from above downwards, showed the following colours:—green, azure, violet, red, and yellow-red (Gmelin’s reaction). Another small quantity of aqueous extract, made alkaline, was associated with milk of lime. The precipitate resulting from the combination of lime and bilirubin was washed in water, and whilst still moist was placed in a test-tube half filled with alcohol acetylated with sulphuric acid, and the whole heated up to ebullition. Thus the bilirubin revealed an emerald-green reaction. Lastly, another carcaeous compound was made with aqueous placental extract and milk of lime, and the precipitate, after having been washed and diluted with water, was acetylated with alcohol and shaken up with chloroform. The bilirubin, in very small quantity, was dissolved by the chloroform, which assumed a yellow colour, whilst the acetic liquid became intensely green on account of the biliverdin (Hoppe-Seyler’s reaction). Further experiments were afterwards used for Gmelin’s reaction, and they, too, gave positive results. I have thus been able to detect even very minute quantities of biliary pigments.

Second Placenta.—This placenta, prepared and triturated like the former one, was placed in a porcelain capsule and rubbed down with distilled water, boiled, and then filtered and expressed. The liquid thus obtained was evaporated in a water-bath, then mixed with water and filtered. With this aqueous extract, the reactions of G melin, Huppert, and that of Gmelin with the modifications of Hoppe-Seyler, were made, and markedly positive results were obtained.

Experiments on Pregnant Animals.—I made use of pregnant bitches and goats in whom the bile-duct was ligatured in order to obtain, within a few days, the maximum diffusion of bile in the tissues of the organism. The number of experiments made were four on bitches and one on a goat. The operations were performed between the twenty-fifth and forty-fifth day of pregnancy. Thus, by studying the influence of the suppressed biliary secretion on the intestine during gestation, I was able to establish that this process is almost invariably with labour at term, fifteen or twenty days and one month after the ligature of the bile-duct, notwithstanding that jaundice was serious from the beginning.

The following experimental method was pursued:—Application of the animal on to the apparatus; chloro-narcosis was made use of for bitches, and morphone in the dose of half a centigramme per kilogramme of the body was employed for the goats. Having prepared the animal the ordinary laboratory technique was adhered to: shaving and washing of the abdominal parietes, first with warm water and soap, then with half per cent. of aqueous sublimated solution, and finally with alcohol. Instruments, gauze and silk were sterilised by boiling. Laparotomy, research of the bile-duct and section of it between two ligatures. Three-strata suture of the abdominal wound, which was closed with colloidine. The urine, carefully collected, began to contain biliary pigments at the end of the first day after the operation. Of the five animals operated on three (two bitches and a goat) were killed the instant blood, and the other two (bitches) were sacrificed before the onset of labour, with a view to examine with accuracy the contents of the uterus, which was immediately removed in its entirety and its coats cut through with great
circumcision, taking special care to cut open, one after the other, the respective amniotic bags and gather the liquor within them. The results of operation were invariably checked by post-mortem examination in order to ascertain the condition of the divided bile-duct. It was noted on opening up that the bitches and goats that were of a normal weight, showed a marked, yellow-orange, particularly so the subcutaneous connective tissue and the peritoneum whereas on cutting open the fetsuses no yellow colouration was noticed in their tissues.

Experiment No. 1.—Bitch weighing 8½ kilogrammes. On March 30th laparotomy was practised as above indicated, along with the ligature and section of the bile-duct at about one centimetre from the intestinal opening. The animal was killed on April 4th and a tense jaundice was noticed. The abdomen was cut into, and the uterus, containing four fetsuses, removed. Experiment No. 2.—Medium-sized bitch, operated on April 16th; killed on the 30th of the same month. On the abdomen being cut open, the gall-bladder was found to have increased in size; the biliary canals, from the bile-duct ligature upwards, were ectatic. The uterus contained five fetsuses. Experiment No. 3.—Big-boned bitch, operated on as above on May 4th, and killed on the 26th of that month. On opening the abdominal cavity, the gall-bladder was found to be markedly dilated. Six fetsuses were contained in the uterus. Experiment No. 4.—Small brindled bitch, operated on May 28th and killed on June 20th. Well-marked jaundice. The abdomen was cut open and the gall-bladder was found very much dilated. In a like condition were found the biliary canals above the place where the bile-duct was ligated. Four fetsuses were contained in the uterus. Experiment No. 5.—Goat weighing twenty-five kilogrammes. Laparotomy, as previously, under morphone narcosis. The ligature of the bile-duct was made, at about two centimetres from its intestinal opening, on December 16th. On the whole, the goat showed symptoms absolutely similar to those of the bitches previously operated on. The animal was killed on January 1st. There was widely-spread jaundice. The abdominal wound had thoroughly healed. Slight adhesions between the epiploon and some intestinal loops. The gall-bladder had dilated to twice its size; the biliary ducts from above the ligature were markedly ectatic. The uterus contained two fetsuses, almost at term. The amniotic liquid, placenta and fetsuses of each animal were placed separately in vials. The placenta were minced into a fine pulp, and some of them were digested in alcohol so as to obtain an alcoholic extract, whilst others were dissolved in water in order to obtain an aqueous extract. The fetsuses were dealt with in the same way, after having been very carefully taken away the liver and the alimentary canal; the amniotic liquid was concentrated and reduced also, partly into alcoholic and partly into aqueous extract. The chemical test of the liquids obtained from the placenta, for the research of biliary pigments, was in every instance positive, with all the reactions before-mentioned. The aqueous and alcoholic extracts of the fetsuses, as well as those of the amniotic liquid, gave the same results. Pieces of tissue digested in alcohol failed to reveal any trace of biliary pigments, whilst the maternal ones show fairly larger quantities of such pigments.

With regard to the placenta, that of the bitch is well known to be circular in shape, with two bags at the edges, wherein the chorionic villi are far less developed than they are in the central part, and wherein accumulations of a greasy nature can be found. The showing, in colour and reactions, great analogy with that of the biliary pigments, though Hammarsten does not admit the identity of this substance with biliverdin to be sufficiently established. It is these two things that we find a fact that this intense dark brown colour, in the case of animals in whom the bile-duct ligature has been practised, whilst the middle part is not in the least coloured with bile, and remains as it is in a normal condition,—i.e., a light brown-red colour, and in this part the villi of the chorion are very richly vascularised and expanded. Under the benefit of my work I extended the research of biliary pigments on pregnant bitches not operated on, and at term, or nearly so. The results given by these pigments were equal in positive, and I am able to assert with certainty that the bitches, or these animals invariably contain smaller quantities of biliary pigments than can be found in those that undergo ligature of the bile-duct. This was already clear at the appearance of the placenta of the operated animals showed edges of a much darker green than the normal placenta. The histological researches of fresh preparations, moreover, showed a much deeper infiltration of green substance in the placenta of operated animals, at times uniform, at other times gathered together into more or less large granules. Chemical researches, carried out on equal numbers of placenta of normal animals and of operated ones, invariably indicated a much greater quantity of pigments into the placenta of artificially jaundiced animals.

Having thus established the truth of this fact in a way too evident to admit of dispute, it was necessary to carry out the same researches on other animals whose presence in the normal state are the same nature substance. For that reason I felt induced to make the experiment on the goat by ligaturing the bile-duct; and, as I have said before, the results, with regard to the presence of biliary jaundice and positive in regard to the placenta, and negative in respect of the fetsus as well as of the amniotic liquid.

Besides the research of biliary pigments, I also testified for the bile-ahcy acids in the placenta of jaundiced animals; for this purpose the placenta were digested in alcohol, and the extract so obtained evaporated and treated with Pettenkofer's reaction (sulphuric acid and sugar) not once was the slightest indication of positive result obtained.

These experiments, I believe, prove more conclusively than has up to now been demonstrated the fact that the mother's jaundice cannot be transmitted to the fetus during intra-uterine life; or, rather, that the biliary pigments cannot directly pass from the maternal blood into that of the fetsus. Consequently, no trace of biliary pigments derived from the jaundiced mother can be found in the amniotic liquid. And it is easily understood that the obstacle is to be found in the placenta, which must be credited with the important function of purifying the mother's blood by preventing the passage of biliary pigments and holding them fast, because they are harmful to the fetus. And that this is actually the case is proved by the fact that no other organ is to be seen, in the above-mentioned observations, so intensely coloured as the placenta, which, on microscopic examination, displays the preference of biliary pigments for its cells, especially accumulating on the margins where the villi of the chorion are less numerous. The transmissibility of certain substances from the mother to the fetus through the placenta has been the subject of much study. Observations and experimental researches, made with cyanate of iron, iodine and bromate of potassium have proved that on being dissolved in the mother's blood they are met with in the placenta. In cases of intoxicated animals and of women poisoned by arsenic, mercury, or lead, the passage of these metals to the fetsus has been demonstrated. With regard to colouring substances, though negative results have generally been obtained for those resulting from fine granules—cinnabar, carmine, India-ink—still, on the face of some positive experiments (Reitz, Perls) on the mother's blood, pigments that are normally present in the placenta of the mother to the fetsus is must be admitted that fine particles may find their way through the placenta, forcing perhaps the cellular strata that separate the maternal from the fetal blood. The question then arises, whether the mother to the fetsus is associated with the question of the relations between maternal and fetal blood. Up to recently some held the opinion that the nutrition of the fetsus took place exclusively by
osmotic phenomena from the maternal tissue towards the chorion, and others that nutrition took place through a particular secretion, a sort of milk elaborated by the placenta.

These two theories are somewhat exaggerated. The two classical works on the function of the placenta are those of Ercolani and of Tafani, who came to conclusions that are the more acceptable ones. The former, who occupied himself with such researches from 1868 up to 1871, maintained that the nutritive blood of the nutritive blood of the fetus does not take place solely by osmotic change between the two bloods, but as well through an elaboration, a secretion of the elements of the decidua, wherefrom the first biliary pigment is formed, and this is elaborated by Ercolani to the maternal placenta, and recognised by Turner.

Subsequently, in the year 1886, Tafani, on studying the placenta of various animals, gave a clear demonstration of the formation of the uterine milk that, according to him, serves for the nutrition of the embryo more especially in the early months, whereas towards the end of pregnancy Tafani held that the osmotic phenomena prevail. By injecting indigo-sulphate of soda into the jugular vein of she-rabbits in the second half of pregnancy, Zung noticed the amniotic liquid was aureo-coloured. He thus wanted to show that part of this liquid is formed by the mother. These statements, however, are sometimes made by the embryologists, but they must be a question of a passage of regular nutritive principles from the maternal into the fetal blood. And this can only take place in the placenta, this intermediate organ, mostly formed by the big branching villi of the chorion that go directly to bathe in a large vascular net developed in the decidua, as already demonstrated. Such a disposition facilitates the exchange between the two blood streams by which the embryo's blood is made fit for the requirements of nutrition. This exchange certainly cannot occur directly, because there is no communication, the will of the chorion being perfectly closed; and, therefore, understanding of the known chemical process of endosmosis and exosmosis, already admitted by the majority. Why, then, are the biliary pigments carried along with the blood met with on the edges of the placenta, and not in the fetal circulation, even in the gravest cases of jaundice? Does the placenta act for such a pigment like an ordinary filter? One might say that, as not all liquids and tissues have equal affinity for the absorbed biliary pigment (there being some less susceptible of penetration, especially those deprived of blood and lymphatic vessels, such as cartilage and cornea), the amniotic liquid and the fetal tissues may have some affinity for the pigment; however, is not a very valid reason, particularly for the fetal tissues, which take the colour well in cases of new-born children with jaundice; it is, on the other hand, better supported for the amnion, which has little vascularity. My experiments agree with those admitting that the passage of even very fine solid particles through the placenta cannot be accomplished, this being an opinion that is gaining more and more favour. Thus the function of an ordinary filter is attributed to the placenta; not in the strict sense of the word, because the way pigmental granules are deposited differs somewhat; but, at least, for the function that consists in the purification of the blood, through its cells, from the biliary pigments, which, by being thus kept behind in the maternal tissues, cannot prove harmful to the embryo. The explanation of this fixation of the biliary pigments in the placenta is to be sought in the calcareous salts therein contained, which have a great affinity for biliary pigments, so much so that chemists avail themselves of these calcareous salts (phosphate carbonatate) as precipitants for the pigments.

Recent studies (a) on that subject have proved beyond any doubt that the placenta, besides containing a quantity of insoluble salts, holds a considerable quantity of calcium, at times so abundant as to be perceptible to the touch in the shape of calcareous concretions. The pigments are carried by the blood stream, on coming in contact with lime, form an insoluble precipitate, resulting from a combination of lime and bilirubin. This calcareous compound would not constitute, for the colouring substances, an element of passage into the body of the fetus, but would, on the contrary, act as the principal factor in the absorption and detention of the biliary pigments in the placenta. Once this is admitted, it follows that no trace of bile coming from the mother can be found in the amniotic liquid. The demonstration of this fact might prove of great value in legal medicine, inasmuch as when these traces are found they are certainly to be attributed to the meconium passed by the suffering or dead fetus in the uterus.

Summing up the results of my experiments, I am led to draw the following conclusions:—

1. Biliary pigments, during pregnancy complicated by jaundice, remain fixed in the placenta.

2. In such cases it has been found, by means of experiments on animals, that biliary pigments do not pass into either the foetus or the amniotic liquid; or, if traces are found, they may be so trifling that no pernicious influence to the foetus can therefrom result.

3. The explanation of such a fact may be looked for in a particular function of the placenta, which acts like an ordinary filter, in order to keep from this pernicious substance coming from the mother.

4. The indication for obstetric intervention may be constituted by the defective condition of the mother's organic resistance, through cholecystitis, and never by the foetus, which is not jaundiced, and cannot, therefore, give rise to imminent danger.

Clinical Records.

DR. STEEVEN'S HOSPITAL.

THREE RECENT OPERATION CASES.

By MR. SWAN, F.R.C.S.I.

(Reported by F. J. Blackley, M.R., B.Ch., Acting Resident Surgeon.)

FRACTURE OF PUBIS WITH OBSCURE BLADDER SYMPTOMS.

A boy, aged 16, was brought to the hospital in the ambulance on August 5th, at 10 a.m. A pony which he had been riding had bolted and thrown him on his right hip, which he stated was in pain. He lost consciousness for a few moments, and on attempting to rise found that he was unable to raise his right leg from the ground. Beyond some slight pain referred to the crest of the right ilium, he complained of nothing. Shortly after admission he made an unsuccessful attempt to pass urine, and a soft rubber catheter was passed without difficulty, withdrawing a small amount of urine and a considerable quantity of blood. A fracture of the pelvis, located as nearly as possible to the right sacro-iliac articulation, was discovered. At 6 p.m., on account of the continued passage of blood and no urine per catheter, and owing to tenderness and increasing dulness on percussion of the abdomen above the pubis, the diagnosis of rupture of the bladder was made. An incision six inches in length was made in the middle line of the abdomen above the pubis. There was considerable ecchymosis of the peritoneum and a large quantity of clear, pale yellow fluid was discovered, which at first was taken to be urine, but a moment afterwards recognised as serum, the result of hemorrhage proceeding from an artery which was freely spouting blood into the peritoneum. The bladder was carefully examined, but no laceration of its wall was found. The vessel having been tied and the blood thoroughly washed out with hot saline solution, the wound in the abdomen was closed in the usual way. Haematuria disappeared eight days after the operation, but the patient's temperature, which had up to this time
been normal, rose to 101°, and the pulse rate to 124.

Pus was discovered in the urine on the same day.

From this date until the 27th his morning temperature was always normal or subnormal, and his evening temperature was 99°. The pulse rate was correspondingly. He felt well, slept well, and had a good appetite. The wound in the abdomen healed by first intention, the passage of urine, though somewhat frequent, was unmattened by pain.

This urine was sometimes faintly alkaline, sometimes faintly alkaline, with a heavy deposit of phosphates and pus. The fracture in the pelvis was evidently ununited, no pain being caused by the anterior superior spine, and the corresponding ala of the right ilium, were deflected, owing to the fracture forward towards the middle line to the extent of an inch.

From the 25th inst., the bladder was washed out daily with warm boracic lotion. On the 30th inst., there was no pus in the urine. As the patient was anxious to be amongst his own people, he was sent home on September 7th.

The hematuria for the first week may have resulted from some slight injury to the bladder, which had not occasioned a complete laceration of its wall, but the cause of the pus in the urine for more than a fortnight was a mystery.

**Intestinal Obstruction Due to a Tumour of the Colon.**

A man, aged 27, was admitted to the hospital on August 17th, complaining of "swelled stomach." For a month previous he had been somewhat constipated, and had had several occasions during this time vomited a large quantity of "green stuff." For three days before admission constipation had been absolute. On examination the abdomen was found to be very distended and tympanitic. Peristaltic movements of the bowels were clearly visible through the abdominal wall, the more so as the patient was far from muscular, and his abdominal wall proportionately thin.

Palpation of the abdomen elicited some pain just below the liver, but no tumour could be felt. The man's family history was of no assistance, and there was no evidence of syphilis. Up to one month before he had been in perfect health.

Repeated enemata resulted in the passage of a small quantity of scybaceous faces, and of a considerable amount of flatus. On August 21st, the patient felt better, but had had no natural motion of the bowels. His abdomen remained in the same condition of distension, and tympany with peristalsis of the intestines still in evidence. A coil of what was probably large intestine remained, being plainly seen passing down slightly to the left of the middle line from the costal margin to the pubis. A rectal examination revealed no abnormality. On the 24th and two following days a considerable quantity of bright blood was passed per rectum, but practically no faecal matter. Some slight discomfort was caused by the great distension of the abdomen, but no pain. By means of a Higginson's syringe the rectum was distended with air, this distension, on examination of the abdominal wall, apparently extending just above the sigmoid flexure of the colon. On account of the persistent obstruction and repeated hemorrhages from the rectum, an exploratory laparotomy was decided upon. Rectal incision was made, a large incision in length was made in the middle line of the abdomen. Coils of large intestine distended with gas bulged into the wound. On tracing the colon it was found that just above the point where it became pelvic, its continuity was interrupted by a hard mass, as far as could be judged about the size of a small orange, and the gut at this point was bound down to the posterior abdominal wall by firm than usual adhesions. Murphy's button, and the abdominal wound closed.

Twenty-four hours after the operation the patient was much relieved by the passage of a large quantity of flatus. On the afternoon of September 6th, he passed two large formed motions immediately followed by Murphy's button, and between 6 and 8 p.m. two more large formed motions. The distension, which had been gradually disappearing since the operation, was completely gone on September 7th, the patient feeling well and having neither pain nor nausea.

The question as to whether the operation will prove a complete cure can only be answered in time, the result depending on whether the growth was benign or malignant; the youth of the patient is in his favour.

**Osteotomy for Hip Deformity.**

A boy, aged 9, was admitted on August 24th with ankylosis of the right hip-joint. There was a history of a fall at the age of 4, followed after a few months by a discharge coming from the joint, and then six months' treatment in a Thomas' hip splint.

From the time the splint was discarded, which was when he was 5 years old, until the present time he did not remember his hip being in any way different from its condition when he was admitted.

On examination, it was found that the femur was absolutely fixed at right angles to the shaft of the tibia, and decided to operate for the cure of the deformity. An incision two and a half inches in length was made over the great trochanter, and extending slightly below it. The femur was divided with an osteotome just below the trochanter, and the upper attachments of the adductor longus, ilio psoas and fascia lata of the thigh cut through. It was then found possible to straighten the leg, and extension being made, plaster of Paris bandages were applied from the chest to the feet by the help of the very ingenious appliance devised by Dr. Halahan, resident surgeon of the hospital.

The patient is now quite comfortable, although there was naturally a good deal of pain for some days, the new position of the limb causing some tension on the nerve trunks.

**Special Articles.**

**British Sanatoria for Consumption.—XII.**

**[By Our Own Special Commissioner.]**

**Nordrach-in-Wales.**

If the returns of the Registrar-General are to be taken as a reliable guide, the death-rate from phthisis in North Wales must be considerably higher than in England and Wales generally. The prevalence of pulmonary tuberculosis in this district appears to be due principally to the bad housing of the working classes, and often, it must be added, to the particularly poor food on which they manage to subsist. In some of the narrow valleys there is much dampness and also great lack of sunlight. Manifestly much of the tuberculosis at present so common in Wales is readily preventible, could the condition and habits of the poorer members of the labouring class be improved.

North Wales has rightly won, and well maintains, a high reputation as a valuable health resort, and particularly Colwylf Bay, Penmaenmawr, Llanfairfechan, and Beaumaris in Anglesea, among the seaside stations, have gained distinction in the treatment of consumption.

Penderyn Hall, or as it is generally called, Nordrach-in-Wales, is excellently situated between Conway and Penmaenmawr.

The sanatorium stands in its own grounds, which are about one hundred acres in extent, consisting of parklands, pine woods and mountain side. Situated immediately beneath hills which rise to an altitude of a thousand feet, it is effectively sheltered from east and north-east winds, and yet well exposed to sunlight and bracing sea breezes. The aspect of the hills is charming. The mountain side has been provided with admirably designed paths which allow of the carrying
out of carefully graduated walking exercise. We consider the arrangement of these paths particularly good, for the walks are so arranged that the patient on the return journey has the way mainly down hill. The excellentscapes in close proximity to the sanatorium afford endless variety for lovely walks, and from almost all parts peculiarly attractive views of mountain and sea can be obtained.

The scenery in many parts of North Wales is unusually heavy, but here it is moderate, being only about thirty-one inches. The average of sunshine is large. The subsoil consists of sand and gravel, and is consequently very porous and dries speedily after rain. The climate generally is healthfully warm and suited to the successful treatment of phthisical cases.

The sanatorium is conducted strictly on Nordrach lines. The resident physician, himself a former patient of Dr. Otto Walther, personally directs the life of each patient, and, with his wife, takes meals with the residents and participates in their manner of living. We had the pleasure of freely inspecting the sanatorium and taking lunch with the patients, and can testify to the excellence of all the arrangements.

The main portion of the sanatorium consists of a stone-built mansion, which by comparatively slight alteration has been excellently adapted to its present purpose. The rooms are of large size and well provided with windows. The dining-room is good, and, indeed, all parts of the establishment testify to much care and thought having been expended in their design, and there is evidence of a rigorous surveillance in their due maintenance. The sanitary arrangements are particularly good, and throughout rational measures appear to prevail.

Near the main building are a number of well-designed and excellently appointed bungalows in convenient communication with headquarters, which are lighted by electricity. Lawns and well-wooded parklands close to the house afford ample opportunity for exercise. The provision of rest shelters for the proprietors and resident physician, Dr. G. Morton Wilson, lives in a charming house in the grounds close to the sanatorium. The doctor and his wife, however, as already indicated, take meals in common with the patients, and practically lead the same life. Only a limited number of patients can be accommodated, and each is given that special individual attention which is so essential for success.

Dr. Wilson is enthusiastic in his belief in the advantages of a management of cases according to Nordrach methods. He lays much stress on the value of carefully regulated and individually directed exercise; and in the following cases the proposition of rest shelters for the nursing staff, and so sink into selfish habits with much less of self-reliance, seeks to arouse a wise spirit of self-help which goes far to secure permanent physical advantage.

The life at Nordrach-in-Wales is so directed as to develop the highest powers of resistance and to secure a full reaction to restorative influences. By a thorough study of each case all the important factors in a rational treatment are carefully regulated to the needs and capacity of each individual.

The terms are five guineas a week, inclusive of medical attendance, board and lodging. Access to the sanatorium is easy; carriages can be sent to meet trains even at Conway or Penmaenmawr stations. The nearest station is Penmaenmawr. The postal address is Nordrach-in-Wales, Capelulo, near Penmaenmawr. Telegrams should be directed "Pencytgwyn, Penmaenmawr."

HANER-Y-FFORDD.

HANER-Y-FFORDD, Queen's Park, Colwyn Bay, although not, strictly speaking, a sanatorium in accordance with the modern interpretation of such a title, is nevertheless an interesting example of a hygienic home specially designed and definitely conducted for the care of its name suggests, it is a half-way house, an intermediary between the sanatorium proper and the ordinary residence. We have carefully inspected Haner-y-ffordd, and consider it excellently adapted for its purpose.

In many cases there are difficulties in sending cases direct to a sanatorium, and also many patients on their return stand in need of further treatment. In such cases we have found Haner-y-ffordd to accomplish much. The ordinary boarding-house and convalescent homes to which so many early cases of phthisis are now sent are usually ill-adapted for the strict control and rigorous regulation of the life of a consumptive, and by the neglect to adopt a rational course of action early in the disease irreparable damage is often done.

Haner-y-ffordd is a newly built and admirably-designed, detached house with a garden of a quarter of an acre. It is situated in the higher part of Colwyn Bay, immediately below the far-famed Pwllycrochan woods, and is well adapted for carrying out the open-air treatment. The house is conducted by Miss Matthews, who has enjoyed considerable experience in the treatment of consumption as matron of Dr. G. Morton Wilson's excellent sanatorium, Nordrach-in-Wales. Miss Matthews informs us that she only receives cases under medical supervision, and only those who are recommended by their medical attendants can be admitted. After careful inquiry and thorough inspection, we are of opinion that Haner-y-ffordd will fill a very useful place in the management of certain judiciously selected cases; and although in great measure experimental, we consider it rich in possibilities of much useful service. The terms are three guineas a week.

MANAGEMENT OF THE WOUNDED IN NAVAL WARFARE.—III.

Haemorrhage.

In naval warfare haemorrhage is comparatively slight with every class and description of wounds. Every shell wound destroys tissues, and bruises more or less extensively the tissues of the surrounding parts; so, whenever an injury is inflicted the vascular tissues sustain more or less contusion and below. When the vessels are rent, their middle and inner coats are first torn and curled inwards; then the outer coat hangs loosely down, so that the coagulation of blood in the vessels is greatly facilitated. Moreover, with a mutilated or seriously lacerated wound, a severe shock will often occur which tends to rely on the action of coagulation, and still more facilitates coagulation. This is the reason why the haemorrhage is so small with shell wounds.

After the Chino-Japanese war was concluded, one hundred questions were drawn up relative to wounds and various sanitary matters, and answers were collected from surgeons. The observations of all the surgeons coincide in showing that haemorrhage was slight. These observations are, of course, of a general nature, and do not hold good for all cases, for there are some cases recorded which were attended with heavy haemorrhage. It depends greatly on the injury to the blood-vessels; when they are rent asunder coagulation is rapid, and accordingly haemorrhage is slight; but, on the other hand, when the damaged or half rent, the middle and inner coats of the vessels being hindered from curling up, coagulation does not take place, and consequently haemorrhage is heavy. Shell fragments and iron pieces are irregular in form, and have sharp angles and keen edges. They not unfrequently give partial laceration to the blood-vessels, besides complete laceration of the lacerated as well as the mutilated wounds, consequently haemorrhage will be severe in such cases.

In two cases of mutilated wounds of both thighs
and of both legs, hemorrhage was observed to have been copious. The arteries of the thigh are too large, even though torn asunder, to form enough coagulation to immediately stop hemorrhage; therefore, if not attended with shock, hemorrhage may continue to the moment of death, and, even if arrested at once, the loss of blood will still be very great. These two cases were caused by the impact of an entire shell of great velocity, and the difference in its effect from that of a wound by a shell fragment is much the same as the difference between being wounded by a sharp sword and being cut with a blunt blade—this probably accounts for the heaviness of the hemorrhage. At any rate, hemorrhage did not last long, for shock was heavy in both cases, and the injured persons died in a few minutes.

As regards shell wounds, it is very rare that injury of a blood-vessel is the sole cause of death. In one case a man received a deep contused wound on the inner side of the lower third of the right thigh by which, the femoral artery having been injured, hemorrhage took place, the bleeding, however, being at once staunched by the application of a compress by a carrier. The patient was brought to the surgery, and was receiving treatment, when the explosion of a shell mutilated his chest and abdomen, and caused instant death.

In shell wounds of all other parts, when blood-vessels smaller than middle-sized are injured, hemorrhage is not heavy, and it will almost always stop of its own accord if dressings are applied. But in cases of injury of the intercostal vessels, the pressure given by the application of dressings does not reach the vessels, and the blood coming out of these arteries flows into the pleural cavity, and does not have such a favourable effect in procuring the coagulation of blood as is the case with the hemorrhage of other blood-vessels, in which the blood, coagulating by degrees in the tissues and increasing the internal pressure of tissues, favours further coagulation. Accordingly, hemorrhage may naturally last till the time of death, and in such cases it is needless to say that timely ligature of the injured vessels is of the utmost importance.

**Suppuration.**

In the case of patients so heavily injured as to need hospital treatment on shore, the wounds were almost all found suppurring when received into the hospital. Appropriate provisions had been made before the commencement of the war to prevent suppuration by strict attention to antiseptic measures. But the result was contrary to expectation, though it could not be helped under the circumstances at that time.

Shell wounds are frequently heavy, and always of a lacerated nature, so that tissues around the wound usually sustain serious contusion; the tissues of the affected surface lose their vitality, and with it their power to resist micro-organisms, and thus even a few micrococci multiply at once and bring on suppuration. This is a fact long ascertained by experience. Moreover, the tissues around the wound are torn irregularly, so that extremely irregular cavities are thus formed, which, once invaded by micro-organisms, cannot easily be sterilised. Hence, in order to prevent the shell wound from suppurring, ordinary antiseptic measures are of no avail; strict precautions must be taken, under careful management. "The usual method of disinfection is, before an operation, first, to cleanse the skin of the part with soap and warm water, next to rub with a brush, and then to irrigate with an antiseptic solution like carbolic acid, followed by a cover of cloth dipped in the same solution. If the dis-

**Germany.**

[FROM OUR OWN CORRESPONDENT.]

**The Deutsch. med. Zeit., September 10th, had a paragraph on a case of Echinococcus of the Kidney under the care of Dr. Schmidt, which was operated on with a successful result. The patient, a woman, aged 31, had seven children. In the summer of 1901 she noticed a swelling in the left hypochondriac region. A tense, smooth tumour, the size of the fist, painful on pressure, was found. On May 12th, 1902, she had another normal labour. In September the growth had enlarged rapidly, and as she was two months pregnant again it was decided to operate. No positive diagnosis was made. Malignant tumour was excluded, and the probable condition was hydro-nephrosis. The operation revealed a tumour of the kidney; the lower portion of the kidney was sound, the growth affecting the upper pole. An exploratory puncture gave clear fluid, which was recognised as echinococcus fluid. About half a litre of clear fluid was evacuated. On opening the tumour a collapsed echinococcus cyst was met with; and was easily re- moved. A portion of the cortex of the kidney, and the hemorrhage showed that it still contained kidney
The recovery and the pregnancy were both uninterrupted. Echinococcus of the kidney was declared to be rare. Amongst 113 kidney operations performed by Krönlein in twenty years, only one out of them was for echinococcus.

The same journal contains an account of the Treatment of Cancer of the Skin by the Cerniz-Truncker Method.

This method consists in painting the carcinomatous ulcer daily with aspiritious solution of arsenious acid in gradually increasing concentration (acid. arsen. 1, distilled water and absolute alcohol each 75 down to 25). After painting over it is exposed to the air. A crust is formed at first clear and thin, then as the painting is continued, it gradually gets darker and thicker, and is so firmly adherent that it cannot be removed. After this is cast off spontaneously, the painting is begun afresh. When the crust that forms is yellowish or greenish and comes off easily it may be taken that all the diseased tissues are cast off; if it still remains adherent, carcinomatous tissue still remains, and the whole process must be repeated. If the skin over the carcinous tissue is still intact it must first be removed with the knife or scissors. The method is applicable to all accessible epitheliomata, provided the glands have not become affected, and the disease is not one of too extensive recurrence. The authors have employed it in five cases of epithelioma of the face. In one case the treatment had to be interrupted before complete recovery on account of a febrile illness of the patient, and in another a patient on whom four operations had already been performed, because a widely-reaching rapid destruction of the new growth took place. In three cases the ulcer skinned over, but in two of them, at least, small recurrences had taken place in the course of a few months. The authors conclude that in the case of a superficial epithelioma gratifying results may be obtained, but that the method does not offer any certainty that recurrence will not take place any more than the knife does, or the thermocautery.

The D. militärärztl. Zeit. reports a case of Ether Paralysis.

A soldier on the march fainting, ether was injected into the middle of the extensor side of the right forearm. The day following there was partial paralysis of the ext. brevis poll., as well as of the little finger. There was partial reaction of degeneration, and as after long treatment in hospital the paralysis did not recede, the man had to be discharged the service invalided.

Ether paralysis was not a mechanical injury to a nerve, but an injurious action of the ether on the nerve (local necrosis and progressive degeneration). If the muscle was injured the paralysis would be the more extensive. For the prevention of such paralysis care should be taken to inject it into the chest, or on the side of the trunk, and only under the skin, without penetrating the muscular covering. If the injection must be made in the arm, there should be only one insertion of the needle, and the spot selected should be the lower half of the extensor side of the forearm. The prognosis of ether paralysis was, however, generally good.

Menière's Disease.

A collective investigation into this disease was undertaken three years ago in Germany, and the results have been reported in a brochure by Dr. Gustav Hermann, of Kiel.

Of the symptoms the author says: We always have an affection of the ears in which the following symptoms are present—disturbance of equilibrium, nausea, with or without vomiting, subjective auricular symptoms with consecutive functional disturbance; or these latter may be absent. In the results of autopsies hitherto published, changes in the ear were always present. These might have their seat in the labyrinth, in the auditory nerve or its nuclei, in the parts of the brain nearest to the ear, in the cerebellum, or, finally, in the middle ear. There was no typical Ménière's disease, as the particular symptoms observed during life had no corresponding post-mortem appearances, and as when the pathological conditions were identical, there might have been symptoms during life not in any way corresponding with each other or to the pathological condition.

The author further discusses the etiology, basing his conclusions on thirty-three cases observed by himself and seventeen by others, and considers the assemblage of symptoms to be the outward expression of an irritation or an injury affecting the central or peripheral nervous element of the auditory organ. The intensity of the symptoms depends not only on the intensity of the irritation or injury, but, above all, on the bodily and mental resistance of the individual affected.

The functional disturbances are greater, other things being equal, when an ear is affected that has already suffered from disease. Regarding the outcome of each case must be judged by itself. If a disease susceptible of treatment (such as syphilis) lies at the bottom, all the symptoms may disappear and the proper functions be restored. Treatment naturally follows the lines indicated by the etiology. Further, the general condition of the patient must be taken into account. Of the acute symptoms the most threatening is the impossibility of movement; on the slightest attempt to rise the patient falls to one side. Even when lying also the patient has the feeling of falling. In some cases the head twists towards the healthy side. In oversensitiveness of hearing, slight sounds may be kept out by tampons in the meatus soaked in glycerine. An ice-bladder on the head is recommended, or an occasional bleeding from the mastoid process, bromides, or Perlmutter dressings.

In the chronic cases there is generally an erosion of the bony semicircular canals or pressure from cholesterolomata. Here an operation must be performed on the canals.

If, on examination, narrowing of the tubes is found or blocking of the nostrils, the respiratory route must be cleared. If the labyrinth is suspected it must be catheterised, &c.

If all remedies so far have failed, the so-called empiric one must be tried. That recommended by Charcot, of quinine in large doses, is risky and endangers the power of hearing still remaining. Better results have been obtained with occasional doses of pilocarpine. As a sedative sulphonal is to be preferred to bromides.

[From our own Correspondent.]

Vienna, September 19th, 1903.

Malformation.

At the Prague meeting, Kleinhaus showed the members a peculiar case of precocity in a child, æt. 4, and measuring 112 centimetres in height—44 inches. The child had menstruated regularly since the first year of her existence. She was fully developed about the breasts and had a profusion of hair on the pubes.

Caesarian Section.

Kleinhaus also showed a patient on whom he had operated for obstructed parturition, first by a trans-
verse fundamental cut, and lastly by Caesarean section. When the normal period had arrived for parturition the passage was found to be blocked by a myoma at the neck of the uterus. An effort was made to remove it, believing it to be lying in the pouch of Douglas, but it was afterwards found to be a pedunculated myoma attached to the posterior surface of the uterus. Finding the difficulty too great the Caesarean section was resolved on, and proved successful to both mother and child.

**Intubation and Diphtheria.**

Ritter next exhibited a child, aged 4½, on whom he had operated for diphtheritic laryngeal stenosis. He commenced by intubation, which was fairly successful for some time, the breathing becoming free and voice clear. Shortly after this, oedema of the larynx and trachea was so great that intubation was precluded and tracheotomy had to be resorted to. Later the granulations from tubal decubitus became so prolific that intubation was precluded and tracheotomy was to be resorted to. After the granulations commenced at the wound in the neck, which relieved the larynx and made the repetition of intubation unnecessary. The child was performed at varying intervals, and with the aid of a bougie the lumen of the larynx was kept open so that breathing goes on quite normally and the voice is clear.

**Necrosis from Bandaging.**

Springer presented a very interesting case of a child suffering from a hemangioma over the parietal bone of the head, for which he operated. The child was a female, aged 15 months. After the operation he applied a "Mitra" bandage passing over the frontal bone and occiput, *lepo aris*, in the routine manner known to surgeons.

Nothing unusual was observed, unless a little disturbed digestion, which was attributed to a catarhal condition of the bowel, with a temperature of 104° F. Shortly after this, oedema of the head was observed from pressure of the bandage, which sloughed, producing necrosis of the bone. He considered a plastic operation would be inadvisable if not dangerous till the nutrition of the child was improved.

**Schwarz asked if the urine had been examined for sugar, to which Springer answered in the negative.**

Bipstein noted that these cases of phantasia in a weak state with catarrh of the bowel were very prone to necrosis, and related a similar case of a child, on whom he had operated for mastitis, who necrosed about the chest afterwards. He concurred with Springer in not operating on such children.

**Perityphlitis or Cyst.**

Springer again showed the society a boy, aged 8, who commenced to complain of pain in the abdomen, with rise of temperature and constipation, which was diagnosed as perityphlitis. The pain at a later period shifted to the left of the umbilicus, at the same time forming a large swelling which fluctuated, giving the impression of a peritoneal abscess. The cyst was finally resolved on and performed, with the result of discovering a large cyst with thin walls lying between the stomach and transverse colon behind the omentum and meso colon. It did not appear to be attached to any of the neighbouring organs, but was presumed to come from a retro-peritoneal source, which he considered unwise to follow. An examination of the contents of the cyst and a part of the cyst wall gave no more satisfaction. A large segment of the cyst was removed and the abdomen closed, which healed up without any further trouble.

**Echinococcus.**

Another patient was shown with preparations of echinococcus taken from the right pleura whence the echinococcus had made its way through the diaphragm. Two of the ribs had been resected to gain access to the sac, which was removed *in toto*, after which the patient recovered within fourteen days.

**Bilateral Paresis of Crico-Arytenoid.**

Schwarz brought forward a young woman, aged 18, with bilateral paresis of the posterior crico-arytenoid muscles. The left vocal cord remained quite still on inspiration, while the right moved outwards. Phonation closed the glottis.

The patient declares the attack came on suddenly after a hasty drink of cold water on returning from a long walk, which caused her to vomit at the time. The breathing became croupy and she snored so loudly at night that it frequently awoke her. She is able to say few words with the clear voice, then a long moaning breath, with an inspiration, before she can proceed further, which breaks up her story into a sort of trisyllabic arrangement.

Syphilis and hysteria must be eliminated from the diagnosis, which leaves the cause very obscure, unless we accept the sudden chilling as the origin. The treatment consists of Parnasation and teaching to speak with long and short intervals.

**Nystagmus.**

This much-debated question has been the subject of many experiments on animals with the object of determining the cause of the disorder. Miners being more subject to the disease than other operatives, it was reasoned that the exposure of the men to discover the origin. Fixture of the eyes in a reclining position was one of the causes given; straining with an imperfect light was another; while Raudnitz comes forward with simple exposure to darkness as the most probable cause.

He confined dogs two months in a kennel in perfect darkness and produced horizontal nystagmus. After allowing them to remain there, the nystagmus disappeared within three weeks. The fundus of the eye remained normal throughout. From this he concludes that the disease, both horizontal and spasmus nutans, is due to irregular pressure in the bulb.

**Acute Lymphomatosis.**

Weinberger gave a further detailed account of the acute case of lymphomatosis, the clinical history was recorded by Lauber on a previous occasion.

The anaemia progressively increased with repetition of the febrile state. On the first examination the erythrocytes were 2,600,000; hemoglobin, 40 to 45 per cent. on June 3rd; and on June 7th they were only 1,400,000, with 25 per cent of hemoglobin. On the 11th they were still further reduced to 1,200,000 and 18 per cent of hemoglobin. Notwithstanding this reduction in the red corpuscles the white were not increased, but gradually diminished from 12,000 to 10,000 till the patient died on June 13th.

The post-mortem revealed extensive lymphatic thickening in the dura mater, gums, ary-epiglottis, kidneys, glands, bronchi, mesentery, &c., &c.

The most noticeable was in the liver, spleen, the marrow of bones, tumours in the orbita, and both orbita as already stated. All the sections gave grey colour, reddish yellow, but never a green. Weinberger was unable to say with the microscope that this was lymphosarcoma.

**The Operating Theatres.**

**GUY'S HOSPITAL.**

**Operation for Removal of a Bony Mass from the Upper Part of the Thigh.** —Mr. Arbuthnot
LANE operated on a man, aged 43, who three years ago had noticed for the first time some fulness and swelling in Scarpa's triangle. This caused him a certain amount of pain, and as time went on he became less and less inclined to use the painful leg, the range of movement in which was within comparatively small limits. He was unable to extend the thigh completely, and from this extreme he could flex through an angle of about 60°. Adduction and abduction were also much diminished. All the muscles of the affected leg were well defined, but the muscle of the left leg was considerably less well developed, and the tenderness in this latter was very distinctly smaller. The reflexes were quite normal. He had at twelve years of age an attack of pain and tenderness in the left hip and thigh, which he was told were due to his rapid growth. As long as he could remember the left leg had been less developed and weaker than its fellow. There was a large deep-seated fluctuating swelling corresponding to the position of the hip-joint and extending downwards below its level. On pressing on it a hard bony mass could be felt in its centre corresponding in position to the lower limit of the front of the neck of the femur. Both the bony and the soft tissues were deeply seared beneath the muscles. Firm pressure on the bony mass gave the impression that it was not very firmly fixed. An incision was made along the anterior margin of the tensor vaginae femoris, and this muscle was hooked backwards. The rectus was seen to be splayed over the swelling. This was partly displaced and partly divided when the front of the capsule of the joint was exposed. It was seen to be very distended with fluid. The capsule was divided vertically, when a large quantity of synovial fluid escaped. There presented between the edges of the divided capsule a rounded smooth mass of bone somewhat limpet-shaped. This moved upon a large prominent facet situated on the junction of the lower limit of the neck with the bone. The facet was projected quite a third of an inch above the level of the adjacent bone. The movable piece of bone with that forming the raised facet was removed. The wound was then closed.

ST. THOMAS'S HOSPITAL.

EPITHELIOMA OF THE TONSIL. Mr. R. L. Lane operated on a man of robust frame, aged about 47, for epithelioma of the right tonsil. The man had applied at the hospital a few days before an account of a sore throat, when it was found that he had a malignant ulcer of the tonsil. When seen in the ward this ulcer was about the size of a shilling, with raised edges, much induration, and occupied the most prominent part of the tonsil, and extended on to the soft palate. There was some redness around it, and the patient complained of considerable pain in swallowing. No enlarged glands could be felt under the jaw, nor was there evidence of disease in any other part of the body. It was decided to explore the glands lying over the carotid and below the angle of the jaw, because it was deemed that these would be best accounted for, though the curved incision was therefore made which exposed the carotid vessels about the bifurcation, and all the glands that could be discovered were removed through this opening. The check was then slit from the angle of the mouth towards the angle of the jaw, a proceeding not accompanied by much hemorrhage, as the facial and parotid glands were made to bleed by the incision. A galena, having been inserted on the left side of the mouth, it was now possible to explore thoroughly the site of the growth. An incision was made next into the soft palate to the right of the uvula, and most of the right half of the palate cut away towards the growth, which was then isolated by incisions behind and below, after which it was possible to bring it some what more within reach. The lower incision involved part of the tongue on the right side, and from this there was some hemorrhage which was not easy to arrest. After the bleeding had been fully arrested two silk stitches were put into the right half of the tongue, closing the wound in it from below downwards. The other side was closed in the same way, and the wounds sutured with interrupted fish-gut sutures, and the wound in the neck closed in a similar way, a drainage-tube being introduced into it. Mr. Battle said that the wound made in the mouth appeared to be rather out of proportion to the size of the growth, but it was only by making a free removal of such growths in their early stage that a prolongation of life could be hoped for. The surrouindings of the glands rendered their secondary infection a very early one. He pointed out that section of the bone of the inferior maxilla would have rendered it easier to get at the disease, but it would have complicated the operation considerably and minimised the patient's chances of recovery, as compound fracture of the lower jaw under such circumstances was very likely to become septicaemic. A little suppuration ensued in the sub-maxillary wound, but otherwise there was little to retard recovery.

OPERATION FOR SUBMENTAL CARCINOMA.—The same surgeon operated on a case of malignant disease of the glands under the jaw in the person of a woman, aged about 45. The case, he said, was one which presented many interesting features. It appeared that many years ago she was operated on for a red, ulcer situated over the chin; there had been no recurrence of this until quite lately, when a small sore of doubtful character developed in the scar, but before this sore appeared she had noticed that a small swelling was forming under her chin. The ulcer had continued for four years, but as it caused no pain she did not attach much importance to it. On admission, she was a thin woman, and with the exception of a small sore on the chin, where there was a large scar, she did not at first present anything unusual; but on closer examination the skin under the chin was rather puckered and the submental region unduly prominent; there was a swelling of stony hardness closely attached to the bone and invading the tissues under the jaw; beyond this solid lump no evidence of glandular infection could be found. The growth was so closely attached to the bone that it was recognised as a necessity, if anything were done, to remove the portion of the bone as well as the growth, and the question was how this could be best accounted for. It was not possible to reduce the least deformity, the skin being very closely attached to the growth in the middle line and for some distance towards the sides, it was necessary to divide the structures outside this. Flaps were dissected away laterally and a portion of the lower jaw removed. By means of a special saw worked by a dental engine in the usual way the parts were made to fit together. The necessary distance from the symphysis. A key-hole saw was then used to divide the bone connecting these two lines of section. The portion was then removed after.
the application of bone forceps. Unfortunately, the bone forceps caused the section on the right side to continue as a fissure through the alveolar process; this involved wiring the jaw after the removal of the tumour. This tumour, which was evidently a carcinoma, extended from the chin nearly to the hyoid, and as it involved the muscles to a considerable extent its excision was not performed without some difficulty, but apparently no growth was left. One or two small hard glands near were also removed. The wound was closed as much as possible with interrupted suture, but not so as to produce some perspiration and depression of it. The patient suffered a good deal from shock, although the loss of blood was comparatively slight. The interesting point in the case, Mr. Battle said, was the occurrence of a carcinoma in this region, probably a secondary growth in the glands after the odontoid ulcer, which must have undergone carcinomatous degeneration before removal, although this was unsuspected at the time. He thought the extreme slowness of the growth and its excessive hardness made it rather more hopeful that the period of freedom from recurrence would be somewhat more prolonged than the extent of the disease would suggest as probable. The fracture due to the bone forceps, he remarked, complicated the operation and made it less easy for the patient to attain a good chin afterwards. The patient made a slow recovery.

In many cases his duty is complicated by the protein manifestations of the zymotics, which render a certain diagnosis difficult or impossible. If time permit, he will often obtain help in doubtful cases by availing himself of the aid of the bacteriologist; but, grateful though he be for such aid, the report he receives is only one factor in that important and complex decision—the diagnosis. Frequently, for the sake of others in the house, or for the sake of the early treatment of the patient—especially in cases of diphtheria—he deliberately takes the risk of sending the patient to hospital on his clinical diagnosis, loyally shouldering the blame, and injury to his practice that may result if his diagnosis be not agreed with by the medical officers of the hospital.

In the light of these facts we must confess to surprise at the action recently taken by the Sanitary Committee of the Poplar Borough Council. The attention of this sapient body having been directed to the number of cases notified as infectious which, on removal to hospital are not considered by the Metropolitan Asylums Board's officers to be so, have instructed their town clerk to write demanding explanations in each case from the notifying practitioners. Moreover, in cases of typhoid fever or diphtheria further information is required as to why the practitioner did not avail himself of the "diagnosis test" offered by the Council. We sincerely hope that the medical men of the district will not allow themselves to be bullied or cajoled into taking any notice of the Council's letters. That they are *ultra vires* is plain from the wording of the Public Health (London) Act; that they are dictated by superb ignorance of the medical and social questions involved is apparent to any practitioner; that they attain the acme of bad taste is obvious to anyone. The medical attendant's own opinion is final as regards his legal obligation to notify; if he thinks that a patient has diphtheria he cannot escape from the responsibility entailed by that opinion. No magistrate, no Lord Chancellor, not even the Poplar Borough Council, nothing but a fresh Act of Parliament, can release him from the liability to notify. Having notified, his responsibility is at an end. To require an explanation of his performance of his legal obligation by the body that pays him half-a-crown is an insult which we as a profession may very justly resent, and should, for the sake of our own honour and dignity, resent. The letters should be treated with the silent contempt they deserve. Not even the tender of another half-crown, which the Poplar Borough Council are not in the least likely to offer, should induce a man to take any notice of these effusions. As to availing himself of the "diagnosis test" offered by the Council, we have already considered the frequent inadvisability of delaying a patient's removal for this purpose, and we repeat that medical diagnoses are not made like chemical reactions by pouring things into test-tubes and looking at them. There is no test for any dia-
gnosis, except a post-mortem. A diagnosis is the summation of a series of factors, and though the Poplar Borough Council may not know it, even bacteriology is sometimes delusive, and even bacteriologists make their mistakes. And if the medical men of Poplar and the bacteriologists make their mistakes, that human failing is shared, we doubt not, by the officers of the Metropolitan Asylums Board, and it may so happen that in many cases the question resolves itself into a legitimate and intelligent and mutually-respecting difference of opinion between the certifying practitioner and the Asylums Board officer. But another party that has made a mistake, we think, is the Sanitary Committee of the Poplar Borough Council. If they endeavour to promote sanitary administration in their area by insulting and brow-beating the local general practitioners, they will find their task more difficult and their work more arduous. The medical practitioner is the informal, day-in and day-out coadjutor of health-administration, and with his back rubbed the wrong way, he may not lend his aid so readily, and things may not work quite so smoothly in consequence. The joints may creak at times. But there is one other point that we must deal with. The Sanitary Committee threaten in the case of the notifying practitioner making a mistaken diagnosis—that is, a diagnosis held to be mistaken by the Asylums Board officers—without having availed himself of their “diagnosis test” to submit his name to the Council. Now, of course, the Council can do nothing. The only object of such a procedure is to brand the medical man with public ignominy—a cruel and unworthy act. We are not lawyers, so that we cannot say exactly how this action would be regarded in the courts, but if ever “malice” could be read into any published document, we should say that this was a case in point. The Sanitary Committee of the Poplar Borough Council have made a mistake; they have exceeded their duties, they have usurped their authority; they have insulted honourable men; they have become exalted with megalomania; they are as beggars put upon horse-back. We fear they will ride to their proverbial destination.

THE BRITISH ASSOCIATION MEETING.

The very close dependence of the science of medicine upon the facts and discoveries of the natural sciences is never, perhaps, so fully realised as when the work of the latter is submitted to a critical and historical survey. On this account, more especially, are the addresses delivered before the British Association of supreme interest to the student of scientific medicine. As twenty years have elapsed since the last meeting of the Association at Southport the period is sufficiently long to render manifest the great advances that have been made in the respective branches of science. In the opening address delivered before the Section of Chemistry by Professor W. Noel Hartley, F.R.S., the main theme was that of spectroscopic analysis as applied to the investigation of both organic and inorganic compounds. A large amount of work has been done in this connection, especially in relation to flame and spark spectra at high temperatures; indeed, the measurement of the spark spectrum of a substance has been taken as one of the chief criteria of its identity. It was the application of this rule that led to the recognition of radium as a separate element, the peculiar physical properties and possible therapeutic uses of which have yet to be more fully investigated. In the Section of Zoology Professor Sydney J. Hickson, F.R.S., in his presidential address, laid stress upon the importance of biological teaching for those who aspire to the attainment of degrees in science, and we might also add in medicine, in our Universities. A sound biological training is very necessary for the proper understanding and due appreciation of the vital principles of cell-activity which underlie every normal and morbid physical process which takes place in the living body. From the public health standpoint, a knowledge of biological facts has many times been of the greatest assistance in dealing with problems concerning such important matters as the purification of water and the disposal of sewage, and this, too, apart from bacteriology. The balance of animal and vegetable life is so delicately poised that a very slight disturbance of equilibrium is sufficient to cause great human discomfort, if it does not actually threaten its existence, and yet this is the very aspect of the subject to which least attention is generally paid by students of sanitary science. The study of the anatomy and life-history of the diptera, by leading to the knowledge of the mosquito Anopheles and its sporozoan parasite, has placed us in a position whereby we may be able to favourably influence the commercial development of certain of our Colonies situated in malarious and tropical districts. The Anthropological Section was presided over by Professor Johnson Symington, M.D., F.R.S., of Queen’s College, Belfast, who, in the course of his address, alluded to the recent advances of craniology, especially with regard to the relationship between the form and development of the cranial wall and that of the brain itself. There can be no doubt that, up to a certain extent, the external shape of the skull affords a good indication of that of the brain, and the recent work of Professor Schwabé, who has shown that the position of the inferior frontal convolution is marked on the surface of the cranium by a small eminence, tends to prove that such is true not only in the main but also in the minor features. The question of the localisation of mental qualities must still remain an open one, but for its elucidation we must look to anthropologists as well as to experimental physiologists for further information. It will thus be seen that medicine is the great borrower and adapter, and that the sister sciences lend themselves freely to her aid, so that any fresh discovery which is capable of benefiting the human race in any way is thereby crowned with an added lustre.
BOARD-SCHOOL DISEASES.

With the advent of new conditions, it is natural to expect fresh accidents as well as beneficial results that have been foreseen. That observation applies with considerable force to the medical aspects of modern popular education under what may still for the present be called the Board-school system. The congregation of practically the whole of the children of the poorer classes of the United Kingdom into the close association of schools, often of large size, has, in the natural course of things, greatly multiplied the field open for the propagation of the infectious complaints to which children are especially prone. A specific infectious complaint, so to speak, has merely to visit a Board school to carry out a wholesale attack, instead of a detailed or guerilla warfare upon single individuals in scattered dwellings. The London School Board, which has done much sterling service in the cause of popular education, has recognised the importance of systematic medical inspection of scholars. They have hitherto employed the "part time" services of a medical officer, whose work was confined mainly to the examination of teachers and other candidates for employment, and to the control of notifiable diseases. Obviously, a great amount of necessary and desirable medical supervision was required above and beyond those particular matters. Accordingly, early in 1902, the Board appointed a medical officer, who was required to devote the whole of his energies to their service. In addition to former requirements, he was specially called upon to supervise (a) the condition of schools—ventilation, heating, lighting, furniture; (b) physical conditions of children—measurements, nutrition, vision, hearing; (c) school work and methods in their hygienic bearing. In this way the foundations have been laid of a really scientific system of hygienic popular education. To attain anything like an approach to the ideal will obviously be a matter of time. At the same time, it is impossible to doubt that a great stride has been taken in the right direction. Viewed in this light, the first Annual Report of Dr. Kerr, the able and energetic officer of the Board, must be regarded as a most important document. With regard to the general question of infection in schools, he strikes at the core of the question in the remark that "the more accurate knowledge becomes, the more likely does it appear that school dissemination is a matter of close personal contagion." It is not the present intention to follow his interesting and often illuminating observations on scarlet fever, diphtheria, measles, whooping-cough, and so on. Something may be said with advantage, however, with regard to ringworm and some of the commoner infectious eye maladies. Of recent years the increase of ringworm amongst children has been enormous, mainly, of course, in the large towns. That fact has been the direct outcome of the School Board system. Sooner or later the absolute control of that malady will have to be undertaken by those responsible for the administration of our national education. The disease is troublesome to treat and disastrous in its results, besides being one of the most readily communicable of all childish ailments. No school system can be considered complete if it does not provide some skilled method not only for the exclusion of scholars affected with ringworm, but also for systematic inspection of the apparently healthy and for the separate treatment of the diseased. As regards eye complaints, there is much in the Report that indicates the necessity of skilled special co-operation. It is suggested, for instance, that "blight" and granular lids are "not matters of serious import as school infections." The results of such teaching might be simply appalling, at any rate as regards trachoma, if accepted by school authorities. Without going into further detail, it may be stated generally that a perusal of the Report leaves a distinct impression that the value of the work done by the Medical Officer of the School Board would be greatly increased were he strengthened by the advice of an authority upon ringworm and of an ophthalmic surgeon versed in the eye complaints of children. While offering this criticism, however, it is with no intention of detracting from the merit of Dr. Kerr's Report, which bears on every page evidence of thoroughness and of competence in approaching a problem of the utmost complexity.

Notes on Current Topics.

The Commission on Dysentery.

When a Government has to do something, and it does not know what to do, it appoints a commission. A Royal Commission generally contains so many heterogeneous elements that its report is followed by one or two minority reports, signed by various members, so that when a small commission (not Royal) can do the work, its report is generally less equivocal. A commission of three is surely the smallest body that could be called a commission, and when it is composed of men of the same profession it might reasonably be hoped that a definite, homogeneous series of recommendations might be forthcoming as the result of its investigations. The Secretary for War probably thought so when he appointed Lieutenant-Colonel Bruce, Colonel Lane Notter, and Professor Simpson to investigate "the nature, pathology, causation and prevention of dysentery, and its relation to enteric fever." The Commission went to South Africa in 1900, and seems to have finished its work by November, 1901, but as the last of its three reports is undated, this is not clear. For some undisclosed reason its full report is only just published—a little late for public interest in the question, though for us there is much food for reflection. Lieut.-Colonel Bruce performed the bacteriological work, and his conclusions are mainly negative; that the South African dysentery is not caused by amoebae or any other discovered micro-organism, that it has no relation to enteric fever, and that so-called dysentery following enteric fever is probably a relapse of the primary disease. Professor Simpson writes a
Jong report, full of his observations, criticisms of the sanitary organisation in the field and in camp, and recommendations for the future. Colonel Lane Notter contents himself with a third report which is a running commentary on Professor Simpson's observations, couched in the most vigorous language that the amenities of commissions permit. Professor Simpson found that "it was the general exception for the water to be filtered or boiled," a statement that Colonel Notter regards as "far from the real facts"; Professor Simpson paints a lurid scene of the insanitary state of the camps, which he attributes to too much individual effort and too little concerted effort, but Colonel Notter considers that the description is "grossly exaggerated"; "there was an organisation, but it was inadequate in personnel"; Professor Simpson makes many suggestions; Colonel Notter thinks them "unworkable," and liable to lead to "friction and failure." The only point on which there is agreement of the authorities is that a special body of officers should be told off for sanitary duties. We suppose the expenses of this unsatisfactory little Commission will not form a large proportion of the £240,000,000 the war cost us, but we fear their little jaunt to South Africa cannot have been a very enjoyable one.

**Human and Bovine Tuberculosis.**

The relationship between the tuberculosis of man and the tuberculosis of cows is being eagerly discussed again, but not a whit more eagerly than its enormous influence justifies and requires. The Germans, pinning their faith to their great tuberculosis master, repudiate the transmissibility of human tuberculosis to bovines—and of bovine tuberculosis to man. For our part we think the evidence accumulated by Professor Hamilton and Mr. Young as to the possibility of the former is too weighty to be neglected. Of their nineteen animals, the same number, be it remarked, as was used by Koch, fifteen became tuberculous after infection with human tubercle, the disease in each case presenting the characters anticipated from the mode of infection—ingestion, ingestion, or inhalation. The number is too large to admit of arguments of collateral or previous infection. We should like to see these experiments repeated on hundreds of calves so that the results might attain an unquestionable authority, but pendente lite we shall not be wrong if we regard the occurrence of the transmissibility as tentatively possible. The far more practically important question, however, is—Can bovine tubercle be transmitted to man? To this there are three answers at present, "Yes," "No," "Yes, but producing a different disease to human tubercle." The latter view is an extremely interesting one, and rests on the observed facts that whereas among adults tuberculous inspection (human tubercle) takes place principally through the inspiratory mechanism, among children tubercle is often apparently acquired by ingestion with resultant ulceration of the bowel or infection of the mesenteric glands without primary intestinal lesion (bovine tubercle). In the child, the milk-drinker, the infection becomes generalised (in those cases that do not recover) by gradual infection through the lymph and blood streams, whilst in the adult generalisation of tubercle following inhalation-infection is the exception. Dr. Nathan Raw points out the similarity of the cultural appearances of the bacilli from children with those of *Pulsum.* We shall watch the development of this theory with interest, but we cannot help regretting that its tendency is to throw the children of the poor more and more on the tinned and preserved milks, whereas sound cows' milk is far preferable and should be obtainable. One fact, we confess, puzzles us. What has happened to the foreign doctors, so belauded of the lay Press at the time, who inoculated themselves with bovine tubercle? If they are still alive, we should like to hear the results of their experiences from them; if they were dead the fact would have reached us long ere this.

**A Tip to Intending Students.**

We have arrived at the season of advice to students. Educational numbers have reminded the parent that the time has come to select a medical school for his son; anon the silver tongue of the introductory lecturer will be loosed. Under these circumstances we feel we must tread cautiously; but a correspondent whose opinion carries weight addresses intending students as follows:—"If medicine is to be your portion—and be sure that you know all that this entails—and if London is to be your educational home, go to a small school. The day of the small school as a self-contained entity is on the wane if we judge the signs of the times aright, but to the average individual, not a genius, never did the small schools offer such golden opportunities. Till recently they had lagged behind, grudging the outlay on the equipment necessary for furnishing the new departments demanded by a rapidly-developing science. This was bad economy, for the students went where they could get the most for their money. They have—too late, we fear—recognised their error and laid out much capital in bacteriological plant and clinical laboratories. But the stream was already diverted, and the provincial Universities, springing from cutlery and hardware like armed men from dragons' teeth, have tapped the supplies of students at their sources. The small Metropolitan school, fully equipped and well staffed, cries like Autolycus for custom. Now our own feeling is that for the man who wants a good preliminary grounding, a large amount of practical work and the certainty of one or two resident appointments—those *summa bona* of hospital advantages—the small Metropolitan school is the best. Entries of a dozen or a dozen and half have been the rule at some of the schools during the last few years, and one, at least, of them has had to advertise for resident officers. Distinction in the athletic field cannot be for them, but for the man who wants to work steadily, and with average brains gain prizes and rewards, the course is clear.
Individual attention and personal supervision can be hardly avoided, so that the "slacker" had better select other paths. In a large hospital he can be easily lost in the crowds, the small school will be too small for him." The only flaw in this reasoning is that the small school "fully equipped and well staffed" is rara avis, indeed it would hardly be otherwise, since the best men naturally gravitate to the larger centres. Nevertheless, the small school unquestionably presents certain advantages peculiar to itself.

**Phthisis or Pulmonary Tuberculosis.**

Out of the chaotic condition of medical nomenclature it is exceedingly difficult to evolve rules of precision, but there are one or two terms from which so much misunderstanding and error arise that we should be glad to see them drop out of currency. Of these "phthisis" is one. Irreproachable in its etymology, its meaning should be well defined. φθίνω is "to waste, decay, wither," and φθορά "wasting, decaying, withering; decline, decay." But this excellent word has come both by ourselves and the laity to be applied so exclusively to the specific "wasting" of the body consequent on tuberculosis of the lungs that to use it of any other disease, such as typhoid fever, would be ridiculous. Having attached itself, therefore, to tuberculosis of the lungs, it is used by many to indicate several other pathological conditions of the lungs not necessarily tuberculous; and by others it is compounded with other terms to mean disease specifically tuberculous. As an instance of the former, one may instance "miners' phthisis," and of the latter, "abdominal phthisis." Now all this is hopelessly confusing. Of abdominal phthisis we can only say that it is better away, and for non-tuberculous phthisis of the lungs we have little sympathy. Miners’ "phthisis" is held by the foremost authorities in this country not to be tuberculous in its inception, although in some cases tuberculous infection may be grafted late in the course of the disease; on the Continent it is held by many to be essentially or originally a tuberculous process. This important distinction is quite lost if the word "phthisis" be employed. Altogether we find that we cannot get back to the plain etymological significance of the term, and its employment to indicate both conditions essentially tuberculous and conditions that one wishes to be understood to be non-tuberculous makes its retention as a useful and definite symbol impossible. We should like to see tuberculous processes specifically called so, pulmonary tuberculosis, intestinal tuberculosis, and so on, and the non-tuberculous chronic inflammations of the lungs designated as anthracosis, silicosis, and such-like, according to their pathology. We fear, however, that phthisis has got such a hold on our vocabulary that we shall not be able to expunge it for many a long day.

**Sleeping Sickness.**

About the beginning of last century Winterbottom, a surgeon in the British Service, called attention to the negro lethargy, or sleeping sickness, as observed by him among the natives of the littoral of the Bight of Benin. But Winterbottom’s "Account of the Native Africans" was forgotten until interest in the subject was revived by Clarke, in 1840. He noticed that, although the disease was common on the coast it was still more so in the interior. The accounts we receive of the epidemic of the disease in the Uganda territory and along the Northern shores of the Victoria Nyanza confirm the accurate observation of Clark. Later writers on the subject were of opinion that the disease was confined to the negro tribes, and that Equatorial Africa was the chief zone of infection. Of course, much depends on the definition of the disease. If the diagnosis is based on the presence of the trypanosoma microbe, the disease so far has not been recognised outside Africa; but if the diagnosis is based on the symptoms, then it cannot be said to be confined to the negro races, or limited in distribution to Equatorial Africa. The district in which the epidemic occurs is infested by a species of tsetse fly. This fly has been identified as the glossina palpalis. It is quite possible that we are on the eve of the discovery of the cause of the sickness. Withal, it is strange that Livingstone, who devoted a considerable time to the study of the tsetse fly, which he found on his first journey to the Zambezi, makes no reference to any ill-effects resulting to any of the natives from the fly, though his account of its effects on cattle is told with considerable fulness. If the disease is due to the glossina palpalis we must find some other cause for the cases of narcolepsy which have occurred in Ireland, and which have been so graphically described by the late Dr. H. W. Foot. The results of the experiments that are being made by the commissioners to see whether the tsetse flies carry the trypanosoma will be awaited with much interest.

**Voluntary Artificial Respiration.**

After operative interference with the cerebellum, the possibility of respiratory failure and the necessity of artificial respiration must always be considered. In the September number of the American Journal of the Medical Sciences, Dr. William Hudson, in "A Contribution to the Surgery of the Brain," records the following interesting phenomenon occurring after the removal of a tumour from the cerebellum. Just as the operation was being completed the patient ceased to breathe, and artificial respiration was resorted to, the pulse being very rapid and of low pressure. It was necessary to continue artificial respiration for more than an hour and in the meantime the patient had come sufficiently from under the anaesthetic to understand what was said to him and to obey instructions. A very curious phenomenon was then observed. As soon as artificial respiration was stopped, the patient immediately ceased breathing, but on being commanded to breathe, he did so. The first few
inspirations were very deep and full, and then they gradually faded away again until he again received a command to breathe—each breathing period being longer than the previous one. This process was kept up for fully an hour before normal respiration returned, and during this period a person was kept by his side to remind him to breathe again each time he ceased. It appeared that this peculiar method of respiration was carried on entirely through the voluntary respiratory apparatus, and that the involuntary respiratory centre did not assert itself for at least two hours after the respiration first ceased. In other words, the attendants kept up artificial respiration until the anaesthetic passed off sufficiently for the cerebral cortex to resume its functions; then the patient continued the artificial respiration himself through the cerebral cortex and its connections with the intercostal muscles until the natural respiratory centre of the medulla had again become active.

The Diseases of Brassworkers.
The march of preventive medicine has accomplished much in late years in rendering the lot of the toilers in factories and workshops less hard and the risks to life less dangerous. Nevertheless, in many of the occupations involving more or less contact with poisonous metals there still remains a disease-incidence among the workers which is sufficiently high. Dr. Herbert Perry, in a paper read before the Birmingham and Midland Counties branch of the British Medical Association, has analysed very fully the various morbid conditions met with in the vast army of brassworkers in the great midland city. Those affected are divided into two main groups—(1) the anemic and gastric, and (2) the pulmonary. The earliest sign of absorption of brass is the green tooth-line, observable chiefly upon the gums in the neighbourhood of the canine and incisor teeth. Pulmonary tuberculosis forms about 20 per cent. of the diseases of brassworkers, as compared with about 6 per cent. of the diseases of the general body of hospital out-patients. Varieties of tremor are also seen among the early manifestations of brass-poisoning. As in plumbism, women seem more liable to be affected than men. The cuter form—the so-called "brass-founders' ague"—attacks the mixers and moulders. It is possible that arsenic, which is found in small quantities in the ore, may become volatilised, and so lead to the appearance of toxic symptoms, especially those of gastric irritation and diarrhoea. The prevention of brass-poisoning may be summed up in two words, ventilation and cleanliness.

The Filigree in Abdominal Surgery.
The difficulty which is sometimes experienced by surgeons in bringing the edges of an abdominal wound together after the removal of a large tumour is one which often militates considerably against the after-success of the operation. In spite of the utmost care bestowed upon suturing each layer of the abdominal wall separately, the best of scars is liable, at any time, to break down during some condition of increased strain with the formation of an unpleasant-looking umbilical or ventral hernia. Some surgeons religiously advocate the wearing of a specially-fitted belt for six months or a year after the operation, while others trust to their own particular method of suturing as a safeguard against any untoward consequences. Dr. William Bartlett, of St. Louis, writing in the *Annals of Surgery*, recommends the plan of embedding in the wound a wire network, or filigree, shaped something like the old fashioned drawing-out hat-rack. It is very easily constructed, being made by bending the wire round nails driven into a board, its form can be altered to suit the requirements of the wound, and, by suturing it to the tissues with fine wire, but by no means necessarily sewing it firmly round, it will efficiently prevent the occurrence of a ventral hernia. Dr. Bartlett does not even consider it essential that the edges of the muscles and fasciae should be accurately adapted, as if the filigree be properly implanted between layers of healthy tissue a good, sound scar will be formed. The results of this innovation have been uniformly successful in six cases out of seven in which it has been practised, and one patient has been under observation for two years. The prevention of stretching of the scar under increased intra-abdominal tension, the readiness with which it can be sterilised, and its ease of introduction, would appear to show that this simple wire contrivance will fulfill all that has been hoped for it in the domains of abdominal surgery.

The Colouring of Foodstuffs.
That the colour of an article of food is not without a considerable effect upon the appetite of the consumer is a fact of which provision-vendors and those engaged in the various branches of the culinary art are not slow to take advantage. From the manner in which brilliant colours attract children and influence them in their choice of sweetmeats it may be inferred perhaps that in them this peculiar attraction is nothing more than the survival of a primitive instinct which will be gradually overcome as years of discretion are reached. This may be, and yet it cannot be denied that even in adults the desire for food is augmented by the judicious combination of colours, especially if these recall certain pleasurable associations or tend to reproduce the natural tints of the fruit or vegetable as seen in the fresh state. In this respect, the sight is stimulated together with the other senses, and these, by mutual interdependence, are the chief factors in the production of the physico-psychical state of appetite. The means by which the artificial colouring of foodstuffs is done becomes, therefore, a question of no small importance from the medical point of view. Even in these days of enlightenment cases now and then crop up where green peas have been rendered of an exceptionally vivid hue through the addition of copper or where the sweets exhibited in the confectioner's shop-window assume a suspicious brilliancy owing to the admixture of the salts of arsenic or lead, even
if only in minute quantities. On account of the failure of the fruit-crop in England this year the market is becoming flooded with foreign-made jams, some of which show very pronounced "natural" tints. In many of these the aniline dyes are employed in order to give a deep rich colour, which is not a desirable practice, seeing that the same result can be obtained by the addition of cranberry or bilberry pulp in certain proportions, which is at least free from objection of chemical artificiality.

The Prevention of Enteric Fever in Armies.

The question of the prevention of typhoid fever among soldiers upon active service is one which must inevitably force itself upon the attention of those who are responsible for the administration of sanitary affairs in the army. There can no longer be any doubt, as Dr. Leigh Canney has so ably pointed out, that enteric fever in camps is practically entirely a water-borne disease, and that if only suitable means can be employed for the efficient and rapid sterilisation of drinking-water, the problem of its extermination will be more than half overcome. That it is possible to render a camp practically immune from the disease by such means is proved by the fact that 10,000 workmen employed upon the Assuan Barrage Works were so protected for a period of four years on the same site, and, in a recent letter to the Times, Dr. Canney has shown that in the three minor wars—Abyssinia Ashanti, and Suakin—where a continuous rapid service of sterilised water to the armies in the field was provided, together with the provision of adequate sanitary arrangements in the camps, the evil was almost completely abolished. The main object of re-opening the subject in the Press is to call attention to the tardiness which characterises the authorities in their organisation of such a service, though it is a matter for some congratulation that the War Office has announced its intention of "taking measures" in this direction. If this be so it seems a lamentable want of enterprise to continue experimenting with old and defective apparatus, when that which is not only far more effective but which is convenient for purposes of transport is ready for use. It is earnestly to be hoped that this comparatively simple and most important preventive measure may be adopted in the full, as upon it our military strength and success may to a large extent depend in the future.

The Antiseptic Properties of Coffee.

For long there has been a popular and semi-medical belief that black coffee possesses some protective power in time of epidemic. In 1833, during a cholera epidemic, the physicians of New York issued a manifesto to the people advising them to drink coffee instead of wine and beer, and an old writer, Daniel Drake, in an essay on cholera, recommended physicians to drink coffee when called out at night or in the early morning. Of late some grounds for this belief have been established, and an additional virtue has been added to those already possessed by coffee, in that it is found to have a distinct antiseptic property of sufficient strength to check decomposition and to possess a germicidal effect on certain forms of bacteria. Drs. Crane and Friedlander have communicated the result of their experiments, made with the object of determining the value of this antiseptic property, to a contemporary (American Medicine). These show that coffee, well mixed into the yolks and whites of eggs, prevented the occurrence of decomposition in the latter; that when coffee infusion was exposed to the air it became turbid on top from moulds, but never turbid with bacteria; and that a ten per cent. infusion of coffee prevented the growth of colonies of, amongst others, typhoid and anthrax bacilli, Bacillus coli communis, Streptococcus albus, and Staphylococcus aureus. Further experiments were made with the object of determining the constituent of the coffee to which this germicidal effect was due, but these were so far without result.

Professional Secrecy and its Limits.

The position of the British physician in regard to the confidence which he owes to his patient is ambiguous and unsatisfactory, and the medical man can appeal to no authoritative guide as to his conduct under special circumstances. As matters stand his attitude is largely a matter of temperament. Some practitioners would rather go to prison than betray a confidence, while others consider that the law absolves them from such obligation. But the law should recognise the rights of the patient and the duties of the medical man as well as the justice due to the community. It would not be difficult to frame a code based on common-sense lines to which medical men might be invited to conform. For instance it should be considered unprofessional for a physician to divulge anything confided to him by a patient unless with the patient's consent, or for the purpose of defending himself when accused, or, lastly, to assist in the punishment of crime. It is obviously contrary to public policy to punish a physician who conscientiously refuses to betray a confidence, and when, in the exercise of his discretion, he decides to testify, it should be before a judge in private. The tendency of late years has been rather in the direction of encouraging medical men to consider themselves privileged persons in regard to matters which come to their knowledge professionally, but judges differ widely in their views on this delicate matter, and it is for the profession to formulate its own rule of conduct, to which judges would be fain to incline.

Cutaneous Hyperalgesia in Appendicitis.

Mr. JAMES SHERREN calls attention (a) to the existence of marked cutaneous hyperæsthesia in a large proportion to cases of appendicitis. This must be carefully distinguished from the more deeply-seated tenderness which is an almost constant symptom. He tests the cutaneous reaction by gently pinching or stroking the skin, beginning at a point free from any disturbance of

(a) Lancet. September 19th.
sensibility. He describes the hyperæsthetic zone as extending from the middle line below the umbilicus in front to the lumbar spines behind, reaching down to a spot about midway between the umbilicus and the pubes. Its distribution, however, may vary within certain limits without losing its diagnostic significance. It is most constant, as well as most marked, in first cases, especially those of the fulminating type, and it may be absent in subsequent attacks, but on the other hand, when once present, it may persist long after all other signs of the disease have disappeared. Disappearance of this cutaneous sensitiveness without a corresponding improvement in the patient’s general condition indicates perforation or gangrene of the appendix, and calls for immediate operation. Whilst the presence of this symptom does not contra-indicate operation its absence gravely affects the prognosis. The age of the patient and the position of the appendix do not appear to influence the production of this cutaneous sensitiveness, and under certain circumstances it may assist in arriving at a diagnosis in doubtful cases.

An Automatic Hand Loom for use in Asylums.

Our attention has been drawn to a new form of automatic hand-loom, the patent invention of the Hon. Robert Flowers, which possesses many advantages that render it particularly suitable for use in asylums. We are informed that the invention is unique in that it represents the steam-power loom without requiring steam, and that, being automatic, the novice with a short experience can do the work of a trained weaver. The machine, once properly set up by a skilled supervisor, is caused to weave by being simply kept in motion by a rocking cast of the slay, the operator’s attention being chiefly occupied with the usual watching for broken threads and other minor accidents. There is no expensive outlay on boilers, furnaces or engines necessary, and the risks of injury to the operator are very slight, consequently it offers manifest advantages for use in asylums, where some such form of industrial occupation for the patients is a vital necessity. We are informed that already the looms have been established and have given complete satisfaction in the Richmond Asylum, Dublin; the District Asylums at Ennis-corthy, Limerick, Cork, Waterford, and Maryborough; the Stewart Institution, Dublin; the North Dublin Union, and numerous other asylums and institutions. It appears to be a contrivance which ought to interest asylum authorities, and which, when it comes more prominently into notice, will be largely adopted. The makers are Messrs. Robert Hall and Sons, Bury, Lancashire.

Vacancies at the Royal City of Dublin Hospital.

The vacancies on the staff of the Royal City of Dublin Hospital caused by the sudden death of Mr. Croly, and the resignation of Sir George Duffy, will, we learn, shortly be filled up. We have already referred to the loss which the medical profession has sustained by the death of so distinguished a surgeon as the late Mr. Croly. Sir George Duffy, in whose case we regret to say that reasons of health have compelled retirement, will leave no less a blank amongst his confrères both in the Royal City of Dublin Hospital and elsewhere. Sir George has been connected with the hospital for many years, and has done much to help to raise it to the high position which it now occupies. In addition to his more practical work at the hospital, Sir George Duffy’s literary attainments are well known. Of late years he has taken a prominent part in the inspection of examinations held by the various qualifying bodies for the General Medical Council. He is a past president of the Royal College of Physicians, of which body he has for many years been a prominent Fellow. We are confident that we re-echo a universal wish when we express the hope that a temporary relaxation from work will bring about a marked improvement in his health. Already, several candidates are in the field for the vacant posts.

The International Congress of Ophthalmology.

The next International Congress of Ophthalmology will be held at Lucerne in September, 1904, and will last three days. It is intended to facilitate the discussion of certain questions in preference to the reading of numerous papers. In consequence all papers, which must be received by the secretary before May 1st, 1904, will be printed in advance and forwarded at least a fortnight before the opening of the Congress to the members thereof. It is hoped by this means to pave the way to interesting and useful discussions, for which, as it will no longer be necessary to read the papers, there will be plenty of time. It is proposed to open a special discussion on the subjects of the indemnity due for loss or injury of one eye. Further information may be obtained from Mr. W. H. Jessop, M.B., 73, Harley Street, W.

PERSONAL.

The estate of the late Dr. W. S. Playfair has been sworn at £46,263.

Mr. W. McAdam Eccles, M.S., F.R.C.S., has been appointed Joint Lecturer on Anatomy, St. Bartholomew’s Hospital, London.

Dr. F. A. Baldwin has been appointed Medical Officer in charge of the Gambia Company of the West African Frontier Force in place of Dr. J. C. Franklin.

Sir William Jesse Collins will deal with the subject of the Institutional Treatment of Inebriety at the meeting of the Society for the Study of Inebriety, on October 13th.

Dr. E. F. Trevelyan will deliver the Bradshaw Lecture before the Royal College of Physicians of London on November 5th, on “Tuberculosis of the Nervous System.”
THE PRE-CANCEROUS STAGE OF CANCER—
"FORCIBLE MASSAGE."

To the Editor of The Medical Press and Circular.

Sir,—In a recent issue "A Correspondent" stated that after studying numerous cases he has come to the conclusion that the "pre-cancerous stage is of inflammatory nature." He seems to think the idea novel, and puts it forth with quite remarkable confidence! Surely that is altogether unnecessary. No one with the slightest experience of cancer can have any difficulty in endorsing his opinion, in respect of a large number of instances. Sir James Paget and, I think, all the leading surgeons of the past generation fully admitted the importance of congestive conditions in leading up to cancer development. Even Walsh, writing in 1846, and under a strong bias in favour of the constitutional origin of cancer, says ("Sea and Sun on Cancer," p. 167): "I feel disposed to admit, from facts observed by myself as well as others, that under certain conditions, at present ill understood, the disease may follow inflammation where, without the occurrence of this process, the cancerous tendency might always have remained dormant."

The view of "constitutional origin" has now become obsolete, that is, if any nebulous hypothesis about cancer ever really existed—a position which the dispassionate onlooker would probably be disposed to question. At any rate, it is generally scouted, and the local development of the malady in a single and limited cell-tract, fully admitted. The last rational foundation for a belief in this constitutional origin rested on the very peculiar phenomena and tendency to re-appearance of mammary carcinoma, and disappeared when I was enabled to trace these obscure
symptoms to their true source—infected of the bone-
marrow.

Now, the most common and obvious example of an
inflammatory condition finally resulting in malignancy is
afforded by epithelioma of the on tongue, mouth.
Often we see chronic ulcers of the lips refusing to heal,
and hovering, as it were, on the verge of cancerous
development for years, before malignancy is definitely
established, and the lymph glands become inflamed.
So in the tongue and mouth a congested and furred
mucous membrane long precedes actual cancer. The
great majority of the patients thus attacked are syphilitic or
commonly both; and it is needful to dwell on the
tendency of alcohol in excess to induce
congestion of the whole alimentary canal. Specialists
who deal with the bladder well recognise the proneness
of chronic cystitis, of whatever source, to generate
malignant developments, although these are some-
times disguised under the designation "papillomata.
So is it with the rectum, and its common congestive
phenomena. So is it with the uterus, and, in fact,
with all malignant developments fairly open to clinical
observation.

On the important question of prophylaxis, it is, I
think, highly significant that malignant disease never
follows fracture of a long bone—an accident which
involves rest and care. On the other hand, peritoneal
sarcomata and other forms of malignant new growths
continually arise from slight sprains and contusions
which pass unheeded.

I am inclined to chronic inflammation as a pre-
cedent of cancer has only just been promulgated ;
and the association, though hardly open to doubt, is not yet
fully worked out. Cysts in the mamma appear in
women at the same period of life as cancer. They
display the same train of antecedents—viz., anything
tendering to hinder the normal devolution of the
organ, its passage from functional activity to senile
rest and atrophy. They ultimately lead to cancer, or become associated with it in various
modes. In fact, mammary cysts and carcinoma are,
in their inception, as often in their naked-eye semblance
twin maladies.

It was to me rather a startling discovery to find the
breasts of women who have never been pregnant filled
with a pseudo-milk secretions. And in the second
place, that instead of cutting out the cyst, or am-
pulating the breast, as I had been accustomed to do, I
could, by expressing this secretion under an anesthetic,
and by rupturing subcutaneously any concomitant
large cyst, cure the patient without incision.

A paper on "Forcible Massage for Mammary
Infections," read at the recent Swansea meeting,
and still awaits publication. It shows that the
primary stage of breast cysts in middle or advanced
life consists in chronic inflammation, erroneously
termed "mastitis," "mastia" would be correct;
"mastitis really signifies inflammation of the nipple.
I do not think that anyone had previously suspected the existence of this novel conclusion,
and the future possibilities of the discovery lie
"on the knees of the gods." But I can hardly
doUBt that we have here also a true "pre-cancerous
stage" of mammary cancer; and, further, that all
induced cancer is preceded by local congestion more
or less insidious and protracted.
I am, Sir, yours truly,
HERBERT SNOW.

6 Gloucester Place, Portman Square, Sept. 17th, 1903.

ACUTE CEREBRO-SPINAL MENINGITIS.

To the Editor of The Medical Press and Circular.

SIR,—Having had my attention attracted by the
release of a pamphlet, current issue of THE MEDICAL
PRESS AND CIRCULAR—"Historical Survey of the Study
of Acute Cerebro-Spinal Meningitis," by Cecil Wall,
M.A., M.D.Oxon., M.R.C.S.—I glanced through its
contents with the interest of one desirous to renew
and improve my former intimacy with an old friend. In the course of the perusal, I
discovered some very startling omissions indeed, even
of some of the most important landmarks in the clinical
introduction of the disease to the English-speaking
profession of the world. But the distinctive feature
of coccicidal menigitis is so conspicuously absent—is that they are all Irish! I have,
of course, no means of ascertaining what may be
Dr. Wall's degree of acquaintance with the work
of the Dublin School of Medicine of the past half
century. Judging from the contents of the communication
before me, it must be very close to the zero plane. For
instance, we are told that "In 1857, Gee and Barlow
published a paper containing the discovery of
cocccicidal meningitis; . . . . retraction of the
head, however, had not been previously noticed as a
prominent feature of the disease, except by Guillemin in
the epidemic at Grenoble [Italics mine.]," as the sum-
mer of 1877, when I happened to be a clinical clerk
in the Houses of Industry Hospitals, there occurred an
epidemic of cerebro-spinal meningitis. To those who
were privileged to attend the clinics of my illustrious
teachers, Dr. Samuel Gordon, and Sir John Banks,
at that period, the above-quoted item of medical
"history" is peculiarly non-instructive!

In the long been so thoroughly and
with the periodic visitations of this disease; and I have
no hesitation in affirming that it is to Irish physicians of the past century that we owe what all capable and
dispassionate critics must acknowledge to be the best
of medical descriptions of its hitherto appeared in the English, or, perhaps, in any
other language. An Irish provincial practitioner,
Dr. Darby, of Bray, gave the first notice of its
appearance in Ireland that was recorded in the year 1846. This dark year of Ireland's history has also
described a dismal celebrity from the fact that its
autumn displayed the full development of the ravages
of the "potato blight," which at that time cost thousands to the horrors of death from complete
starvation. In August of the same year, Dr. Mayne,
of Dublin, published his classical description of the
symptoms of "cerebro-spinal meningitis," as it then
appeared in the North Dublin Union Workhouse.

In France, where the disease had been known long
before its recognition in the British Islands, it
committed great ravages from 1837 to 1849, displaying a
frequent and fatal prediction of typhus fever, especially for the persons of young conscripts who had
recently been drafted into the army. That the disease is
an old one there seems no reason to doubt; but
unfortunately the older medical literature fails to
show that descriptions of the specific febrile conditions
in the preceding centuries were almost metaphy-
ical in their vagueness. And we can hardly
recognize a definite description of this disease
still we come to that of Vieuxseux and Mathey,
of an epidemic which visited Geneva in the
year 1805. In the following year it appeared in the
United States of America, where it prevailed in various
localities, as also in Canada, till 1819. During the
period of the great mid-European campaigns of Napo-
leon's wars—between 1805 and 1814—many visitations
were recorded in different localities, notably in the
armies and prisons of France. In most of the earlier
cerebro-spinal epidemics of the last century the disease
displayed a startling degree of malignity. At Avignon
one prominent physician lost twenty-nine of his first
cases; and, in general, the average mortality of
those earlier French epidemics in said to have num-
bered 80 per cent. The earlier epidemics in Ireland
displayed a marked predilection for the persons of
boys. This feature has continued through the years, but
it has not been quite so pronounced in the later ones.

Unlike the more defined eruptive fevers, cerebro-spinal
meningitis pursues no definite course; and there is,
accordingly, no specific limit of duration. In the
earliest cases of the Danish epidemic the fatal
termination was reached with a thrilling degree of
rapidity. Dr. Mayne notes that he had known
deaths to occur within forty-eight hours, and refers to reported deaths within fifteen hours. A case occurred in the practice of my late honoured teacher, Dr. Samuel Gordon—one of the keenest clinical observers of his generation—in which death occurred within five hours. The patient, a big-pupil of the Bluecoat School, sang in the choir at 11 a.m., and died of cerebro-spinal meningitis at 4.30 p.m. on the same day. On account of the usual involvement of the sheaths of the nerves of special sense many of the small proportion of survivors recovered with permanently damaged sight or hearing—or both—in the earlier epidemics; also, for corresponding reasons, with various degrees of mental lesion, and sensory and motor paralysis. The Dublin epidemic of 1900 was much less fatal than its predecessors, and the disastrous sequelae were not so numerous or so marked. Although varying very considerably in different cases, the symptoms of this disease are extremely characteristic. One can hardly fancy an intelligent practitioner reading the original descriptions of Drs. Darby and Mayne, and then feeling any doubt as to the diagnosis of even his first case. Of course, the absolutely crucial test of the scientific pathologist of the present day, for the decision of diagnosis, is applied by removing some of the cerebro-spinal fluid of the patient by 'lumbar puncture,' and carrying out the usual series of culture experiments. If the suspected Diplococcus intracellularis meningitidis satisfactorily responds to those queries, the diagnosis will have been established beyond dispute. I may remark parenthetically, that in a malignant case, where early diagnosis is most important, the patient will then be dead.

In closing these remarks, I must apologise for the length of my communication; but venture to express the hope that you will be able to give it a place in your columns in the interest of clinical "history" in general, and of the share contributed to making it by the Dublin School of Medicine in particular.

I am, Sir, yours truly,

JOHN KNOTT, M.D.
34 York Street, Dublin, Sept. 5th, 1903.

Obituary

WILLIAM IRVING PAGE, M.R.C.S., L.S.A.

Mr. William Irving Page, of the White Cottage, Shanklin, Isle of Wight, and formerly of the Green, Wimbledon Common, died at Oulton Broad, Lowestoft, of pneumonia on Sunday last. A student at the medical school of St. George's Hospital, where he was some time house surgeon, he was admitted a member of the Royal College of Surgeons, England, in 1862, and a licentiate of the Apothecaries' Society in the following year. He practised at Wimbledon, and was Surgeon to the Wimbledon Cottage Hospital and Dispensary, and Medical Officer of the Fever Hospital Durnford Lodge. Mr. Page was a member of the Royal Geographical and Astronomical Societies.

JAMES FERGUSSON, F.R.C.S.Ed.

Mr. James Fergusson, F.R.C.S.Ed., died at his residence, Lincoln House, Richmond, on Saturday last at the age of sixty-seven. Mr. Fergusson, who was educated at the University of Edinburgh and the Royal College of Surgeons, Edinburgh, passed the Licentiate's Examination of both the Royal Colleges of Physicians and Surgeons in 1866, being Gold Medallist in Physiology and Natural Jurisprudence, First Prize-man in Medicine and Clinical Medicine, and taking honours in obstetrics and gynaecology. He was elected a Fellow of the Royal College of Surgeons of Edinburgh in 1881, and he was a member of the Dermatological Society of Great Britain.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list:

And & Son (London).

King's College Hospital Reports. Vol. VIII., January 1st to December 31st, 1901. Pp. 476. Price 7s. 6d.

Balliere, Tindall & Cox (London).

Aids to the Feeding of the Infants and Children. By John McCaw, M.C., L.R.C.P. Pp. 120. Price 2s. 6d.

Baillyres et Fils. (Paris).

Les Médications Reconstituentes; La Médication Phosphorée. Par Henri Labbe. Pp. 95. 5s. 6d. net.

The Health Resorts Bureau (London).

Hodder & Stoughton (London).

K. H. Lewis (London).

How to Take Care of a Consumptive. By M. Forrest Williams. Pp. 47. Price 1s. net.

David Nutt (London).

Sampson Low, Marston & Co. Ltd. (London).

Smith Elder & Co. (London).

The Edinburgh Press, Ltd. (London).

William Wesley & Son (London).

A Laboratory Manual of Physiological Chemistry. By Ralph W. Webster, M.D., Ph.D., and Walden Koch, Ph.D. Pp. 197. Price 6s. 6d. net.

John W. & Co. (Bristol).

Memorandum of the Interests. By Prof. Dr. Carl von Noorden. Pp. 54. Price 2s. 6d. net.

Nephritis. By Prof. Dr. Carl von Noorden. Pp. 12s. 6d. net.

Medical News.

The Recent Epidemic of Small-pox in Dublin.

We have received a copy of the Report of the Public Health Committee of the City of Dublin in the recent epidemic of small-pox. The epidemic commenced in February, 1902, and continued until July, 1903. The first case notes was that of a man in a nightly lodging-house in Townsend Street, who contracted the disease in Glasgow. By the removal of all the occupants of the lodging-house to a Corporation refuse the disease seemed to have been stamped out, and probably was so. In August a case of the disease was brought to Cork Street Hospital, where a second developed, and in December
a third case was detected on a Liverpool ship and brought to hospital. According to the report, three cases infected a boy and a girl in Cork Street Hospital, and helped to spread the disease. But the disease did not approach the dimensions of an epidemic until the outbreak of a marked example in a tenement house on St. Stephen's Street, containing thirteen families. The difficulty of limiting the area of infection is increased by the existing means of transit, thus a nurse suffering from the disease travelled in a tramcar from Baggot Street to the North Circular Road, about four miles. How many did she infect during that journey? And how many did the car infect before it was disinfected? The number of cases rapidly increased, there were but two in January, 1903, and in the following April there were sixty-eight. The total number of cases was 255, of whom 135 were males and 120 females. There were 33 deaths, showing a mortality of 12.9 per cent. The reasons for assuming that the girl in 50, Church Street, caught the infection in the Cork Street Hospital are set out fully on page 549; but we incline to the verdict "not proven." During the thirteen days the girl was in Church Street she may have contracted the disease, though we confess there is much to be said in favour of the view that she carried the infection from the hospital. On March 11th, a dealer in second-hand books was attacked with the disease. He had just imported the books from Liverpool, where the epidemic was then epidemic. We refer to the report simply to show how difficult it is to guard the public from infection by other means than vaccination. There are three excellent illustrations in the report, which exhibits a marked tendency to speak in eulogistic terms of the excellent example they set and the desire they evinced to profit to the fullest extent by the instruction imparted to them by the professors.

**Release of Mr. W. Manuell Collins.**

Mr. Collins, who was sentenced to seven years' penal servitude in 1898 for performing an illegal operation, was set at liberty last week in consequence of illness. His name had previously been removed from the Medical Register on account of a conviction for forgery.

**The Plague at Marseilles.**

No fresh cases of plague have occurred at Marseilles, and it is hoped that the epidemic is now at an end.

**Death Under Chloroform.**

A young woman, aged 18, died under chloroform last week at Musselburgh, N.B., after the extraction of several teeth. Efforts to restore animation were maintained for an hour, but in vain.

**Amputation Mortality at the London Temperance Hospital.**

The following figures have been prepared by Mr. J. Stroud Hosford, Surgical Registrar to the London Temperance Hospital from the records of patients under the charge of Sir William Job Collins, Senior Surgeon to the Hospital:

*Advanced morbus coxae, amyloidosis.
**Sarcoma, secondary growths in pelvis and liver.

In this case only was alcohol administered.

**Lectures on Health.**

The syllabus of health lectures drawn up by Dr. R. J. Collie, Medical Superintendent of the Hygiene and First Aid Classes of the London School Board, is a model scheme for instruction in elementary hygiene. First we have the hygiene of the dwelling, with practical demonstrations to illustrate the principles involved, followed by the consideration of what ventilation means, with an outline of description of air, and its importance to living organisms. The third lecture deals with clothing. Incidentally a lecture is to be devoted to the prevention of consumption and the care of the skin. Exercise, personal hygiene and instruction each forms the subject of an object-lesson, winding up with "water" and the prevention of the spread of infectious diseases. Special lectures, intended for schoolmen only, are sketched, bearing on the care of infants and the causes of ill-health in women, with practical considerations on the art of cooking. If we wish to raise the health standard of the community it must be by means of instruction on these lines, and we would recommend everyone who contemplates lending a hand to obtain a copy of this syllabus as a guide, for it is well thought out, and covers the whole ground. Only the heads are given, the details being left to the discretion of the individual lecturer.
Notifications to Correspondents, Short Letters, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by adhering to this rule.

Correspondents are kindly requested to send their communications, resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending such subscriptions, the name and address as to whom the subscription is applied for must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ERRATUM—Reprints of articles appearing in this journal can be had at a reduced price, and will be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Bailly-Munster.—We are not in possession of sufficient data to enable us to form a trustworthy estimate of the value of the practice. You had better apply to an agent, who will place the matter on a business footing.

Dundee.—We see nothing improper in the sending round of the "change of address" card, provided of course, that it is sent only to persons likely to be interested therein. In any case, if only sent to medical men it can scarcely be regarded improper.

We have received the following from a correspondent. It appears to us to merit consideration:

WANTED—A DISPENSARY DOCTOR.

"M. O. (K. E.)" required for Ballymore.

Desires to do the Guardians' monkey-work,

Or, in polite terms, to tend the poor.

But he may be anything you like—a Turk.

Or something ethnologically lower,

And if we will not hire him, he won't hear

His duty for such small considerations.

As payment—and will shun Associations.

There was a time (the Halcyon time of yore) when this was the right way to pass your fellows—

These fudging doctors—are they learnt to soar

Beyond the "sweat box" (a) or kitchen bellows

(Excuse the rhyme) ; that is to say, before

The I.M.A. became so zealous.

For every vacancy, a score or two, perhaps—

That was the time for sitting on your chaps !

Mals remors—will no unburden Galen.

Or older, with some pluckings to his credit

Take Ballymore? He need but come and sail in

He'll get a hundred pounds—the Board has said it

That may succeed in flushing him—original is;

And, if he doesn't like it, he can shed it.

In which case he wouldn't be a "star."

The Guardians won't be too particular.

Some Parliam, for instance, not objecting

To isolation from his fellow-man;

Not to office, and not to preferments.

A more ambitious scale of living than

Beats a practice also unappreciating.

Especially when Guardians work the plan

Of helping business (which I think is wicked)

Yet giving likely candidates a chance.

L'Exced.

Wanted, a doctor for Ballymore !

This is the plaintive cry

Age between twenty and four score—

He needn't have any practice before

No matter, so long as the rates are low,

If doctor or patient die.

Wanted a doctor for Ballymore !

A district a-begging ! Who'll buy ?

For further particulars, candidates will apply to the Clerk of the Board of Guardians, Ul. Union.

(1) At Guardians' meeting the other day, a member stated that the doctors would soon be standing behind bacon-boxes.

Appointments.

Brydon, John, L.R.C.P., L.R.C.S.Edin., L.P.P.B.Glasg., House Surgeon at the Hartlepool Hospital, Hartlepool.

Conlon, P. W., L.R.C.P., L.R.C.P.I., Consultant Surgeon under the Factory Act for the Ballyshannon District of the Counties of Donegal and Ferns.

Henchley, A. R. E., M.D., Clinical Assistant at the Chelsea Hospital for Women.

Hosley, John, M.D. St. And., Medical Officer of Health of the Bedford District Council.

Knight, Wilfrid E., M.R.C.S.Edin., Senior House Surgeon to the West Ham and East London Hospital.

Light, L. W., L.R.C.P. Lond., M.R.C.G.Eng., Medical Officer to the Bradwell District Council, Lowestoft.

Morgan, C. Howard, M.R.C.S., L.R.C.P., Clinical Assistant at the Chelsea Hospital for Women.

Nield, R. W., M.B., Ch.B.Ire., Medical Officer of the Cummerworth Division of the Huddersfield Union.

Robertson, A., M.D., F.R.C.S., Clinical Assistant at the Chelsea Hospital for Women.

Vacancies.

Ballyshannon Union.—Medical Officer. Salary £120 per annum, with Vaccination Fees, also to act as Medical Officer of Health, salary Union. (See advert.)

£20 per annum. Immediate application to J. B. Chibb, Clerk of Bradford Poor-law Union.—Resident Medical Officer for the Sanatorium for Convalescent. Salary £150 per annum, with raisons, apartments, and washing. Applications to Thos. Crowther, Clerk to the Guardians, 22 Manor How, Bradford.

Lancashire County Asylum, Wigan.—Consulting Medical Officer. Salary £150 per annum, together with furnished apartments, board, air, and washing. Applications immediately to the Medical Superintendent.

Manchester Children's Hospital, Fallowfield.—Medical Officer. Salary £180 per annum. Application to R. W. W. Scott, Secretary, Manchester Dispensary, Gartside Street, Manchester.

Parish of St. Giles, Camberwell.—Medical Officer. Salary £180 per annum, with furnished apartments outside the Workhouse and an allowance of £1 weekly in lieu of board and washing. Applications to Charles S. Stevens, Clerk to the Guardians, Manchester Guardians' Office, 29 Peckham Road, S.E.

South London Hospital.—Assistant for small Hospital in South London. Honorsium 10 guineas. Applications to Secretary, 19 Mann's Place, Henrietta Street, Covent Garden, London. (See advert.)

Southampton Incorporation.—Resident Assistant Medical Officer. Salary £130 per annum, with apartments, board, and washing. Attendances. Applications to David P. Gillow, Clerk to the Guardians, Clarendon Office, Workhouse, Southampton.

Southwark Union, London.—Medical Superintendent. Salary £150 per annum, with furnished apartments, board, and washing. Applications to Howard C. Jones, Clerk, Union Office, John Street West, Blackfriars, S.E.

Surrey Dispensary, Southwark.—Resident Medical Officer. Salary £160 per annum, with furnished apartments, coal, gas, and attendance. Applications to W. B. Miller, Secretary, 69 Borough High Street, Southwark.

West Herts Infirmary, Hemel Hempstead.—House Surgeon. Salary £100 per annum, with furnished rooms, board, fire, lights, attendance, and washing. Applications to Percy Hall, Hon. Sec.

York Dispensary.—Resident Medical Officer. Salary £200, if it was easy, with board, lodging, and attendance. Applications to W. Draper, Esq., De Grey House, York.

Births.

Arley.—On Sept. 17th, at 12 The Avenue, Southport, the wife of P. H. Arley, M.R.C.S., L.R.C.P., D.P.H., of a daughter.

Buckley.—On Sept. 17th, at Almack End Infirmary, Hackney Road, London, N.E., the wife of Dr. J. Harley Brooks, Medical Superintendent, of a daughter.

Lemmety.—On Sept. 17th, at 90 Manor Road, Stoke Newington, the wife of R. A. Lemmety, M.B., of a son.

Marriages.

McClintock—Irvine.—On Sept. 16th, at Great James Street Church, Londonderry, Lawson Tait McClintock, M.B., Ch.B., of Londonderry, young son of the late Dr. David McClintock, Clough, Lough Erne; to Miss Sterton, Ballyo, to Louise Maid, second daughter of the Rev. R. Irvine of Greencastle. Londonderry.

Winder—Irvine.—On Sept. 17th, at St. Paul's Church, Portman Square, Herbert Winder, M.D., R.A.M.C., to Esther Amabel (Estie), younger daughter of E. Gardner, of Bicknell Mansions, Portman Square, and Clear Green, Errol, Perthshire.

Deaths.

Bradshaw.—On Sept. 20th, at 122 Holland Road, Kensington, suddenly, William Bradshaw, M.D., in his 65th year.

Brown.—On Sept. 17th, John Ansell Brown, M.R.C.S.Eng., of 9 Russell Road, Kensington, W., aged 55 years.

Burroughs.—On Sept. 16th, at Leighton Buzzard, Edward Burroughs, second son of the late J. E. Burroughs, Surgeon of the Lee, Kent, aged 55 years.

Saucier.—On Sept. 14th, at Crowborough, Sussex, Isabella, the beloved wife of Deputy Inspector-General George Saunders, M.D., C.B.
Original Communications.

OPHTHALMIA NEONATORUM: ITS ETIOLOGY AND PREVENTION. (a)

By SYDNEY STEPHENSON, M.B., C.M.,
Ophthalmic Surgeon to Queen Charlotte’s Hospital, &c.

In the opinion of those well qualified to judge, ophthalmia neonatorum is the cause of more blindness than any other local disease, excepting, perhaps, atrophy of the optic nerve. Magnus estimated that in Germany it accounted for upwards of 10 per cent. of his 2,528 cases of blindness, a result substantially confirmed by Trouseau in France, by Schafer in Russia, and by Oppenheimer in America. The Royal Commission on the Blind, the Deaf, and the Dumb, which reported in 1889, estimated that about 7,000 persons in the United Kingdom had lost their sight from the disease. This number of disabled people may be taken to represent an annual burden upon the commonwealth of £350,000, or upwards of one-third of a million pounds sterling.

It has been proved to demonstration that in ninety-nine cases out of one hundred ophthalmia neonatorum is preventible, and that it may be prevented, moreover, by the use of a few simple precautions.

It would be a mere truism to say that the term "ophthalmia neonatorum" is applied generally to every inflammation of the conjunctiva in a newly-born baby. But there is ophthalmia and ophthalmia. Some of the forms are harmless or nearly so, whereas others are grave enough to account for a large percentage of blindness. As regards the serious class, it may be stated that they are almost invariably due to the specific microbe of gonorrhoea, while the others are associated with microbes of several different kinds.

Our first point of inquiry, accordingly, may be directed towards ascertainin what proportion of cases the gonococcus can be demonstrated.

Our statistics show that in the practice of seventeen observers, gonococci were found in 61.63 per cent. of the 1,577 cases. The proportion ranged from a minimum of 35 per cent. to a maximum of 100 per cent. The differences thus brought to light are somewhat striking, a fact that may be accounted for in several ways, of which perhaps the most important are (1) the social class of the patients, (2) the methods of bacteriologic diagnosis, and (3) whether the disease had been treated or not before the discharges were examined for gonococci.

Among seventy-six cases of ophthalmia neonatorum recently investigated by me, gonococci were found in forty-one, or 53.94 per cent. Adding to the foregoing the figure of one I published a few years back on this subject ("Ophthalmia in Newly-born Children," 1898) it will be found that of my 121 cases of ophthalmia neonatorum, gonococci were demonstrated in seventy-one—that is, in 58.07 per cent.

The total number of cases at our disposal, then, is 1,498, and gonococci were present in 60.17 per cent. As the numbers dealt with are tolerably large, we shall scarcely err if we assume that about two-thirds of all cases of ophthalmia in newly-born babies are due to the micrococcus of gonorrhoea. The practical importance of this generalisation lies in the fact that in ophthalmia the cornea seldom survives the gonococci to be the cause of the conjunctival inflammation.

It will be apparent, therefore, that a first necessity in the more exact diagnosis of ophthalmia neonatorum is the bacteriological examination of the secretion from the conjunctiva. In my opinion, no figures of so-called "purulent ophthalmia" should now be accepted unless this obvious precaution has been taken. It is true that, after some practical experience, there is not much difficulty about identifying most cases of true gonorrhoeal ophthalmia, but the diagnosis can never be said to rest upon a certain and scientific basis unless gonococci are actually demonstrated. There are, indeed, cases where the signs are so slight that nobody from a casual examination would suspect that gonococci lay at the root of the mischief, and no amount of mere clinical experience will enable one to identify such cases with even a tolerable approach to certainty. The following is such a case recently met with at the North-Eastern Hospital for Children. Wm. B., aged 19 days, was brought on February 26th, 1902, with his right eye inflamed. He was the first child, and was born at term, after a natural labour. His eye became inflamed on the seventh day, so that we clearly had to do with an instance of "secondary infection." It showed a little yellowish-white discharge; the lids were neither swollen nor reddened; the eye could be well opened by the baby; the cornea was clear; and the tear passages were apparently normal. A note was made at the time to the effect that the case did not resemble the gonorrhoeal form of ophthalmia. Nevertheless, by means of cover-glass preparations gonococci were found to be tolerably numerous in the discharge from the eye. I could quote several similar cases.

The difficulty of diagnosis is certainly not lessened by the existence of so-called "abortive" cases of gonorrhoeal ophthalmia, of which a good instance has lately been reported by Dr. E. Ammann (Klin. Monatsblatter f. Augenheilkunde, xxxi., 1897, p. 307). In that case the infant, when seen on the fifth day after birth, showed a trivial conjunctivitis, the symptoms of which were stated to have existed from birth. It was associated with gonococci. The usual treatment was prescribed, and on the following day, the secretion had much diminished, and it disappeared, along with the other signs of inflammation, in a very short time.

On the other hand, what looks clinically like a case of gonorrhoeal ophthalmia sometimes proves, on bacteriological investigation, to be associated not with Neisser's cocccus, but with some other micro-organism, especially with the pneumococcus or the bacterium coli. There is no need to occupy time by quoting cases in support of this statement.

It may be fairly concluded from what has been said that gonorrhoeal ophthalmia cannot be diagnosed in the absence of a bacteriological examination of the discharge from the eye, a point in which it resembles gonorrhoea itself.

In my experience, the bacteriological diagnosis of
gonococci offers no particular difficulties as regards secretion from the conjunctiva, whatever it may do in other parts of the body. I can hardly help thinking that there has been a little tendency to exaggeration in some quarters as to the difficulty of the differentiation of these organisms. Microscopically the gonococci appear as small ovoid bodies with somewhat irregular borders and often a transverse row of smaller bodies. The females of these organisms are all of fairly uniform size, the intracellular groups of numerous biscuit-shaped diplococci, which are readily decolorised by Gram, but which retain the basic aniline dyes with some tenacity, are very characteristic. Indeed, cultures would not be necessary were it not for the fact that England (Klin. Monatsbl. f. Augenheilk., 1900, Beilageheft, p. 72) has recently described a case of severe purulent opthalmia in a baby born three and a half months before, in whom it was possible to distinguish the gonococci from other intracellular diplococci, which by means of cultures were shown to be the Diplococcus intracellularis meningitidis of Weichselbaum and Jaeger. Moreover, it is possible, although the author denies the fact, that the same microbe was observed by Krakenburg (Klin. Monatsbl. f. Augenheilk., 1899, p. 271) in conjunctivitis, and called by him the "pseudo-gonococcus." (a) Hence, in order to differentiate between the two microbes—the gonococcus and the meningococcus—it appears that we must inoculate agar-agar and incubate the tubes, when the former organism will not grow, while the latter will yield an abundant, whitish, cultivation. It must, however, be noted that, so far as I am aware, Diplococcus meningitidis has not yet been found in the opthalmia of newly-born babies.

The opthalmia produced by organisms other than the gonococcus, generally speaking, agrees in the following particulars:—It is moderate in severity, and, except when due to the Klies-Lofeßer bacillus, seldom affects the cornea. Thus, of thirty-eight of my gonorrheal cases, exactly 50 per cent, showed corneal damage, while of thirty-nine non-gonorrheal cases, the cornea was affected only in 17.94 per cent. Some of the latter were almost certainly gonorrheal, but as they did not come under treatment until late in the disease, gonorrhea could not be demonstrated.

Many investigations have been made into the bacteriology of the normal conjunctival sac, but, curiously enough, no little difference of opinion still exists with regard to the subject. One school, represented by Arnold Lawson, Franke, and Jameson, holds that the healthy conjunctiva is often relatively sterile, whereas a second school, of which Morax, Randolph, and Gifford are the chief exponents, believes that such organisms as the B. aeroides, the S. phlegmonis, and the S. epidermis albus are practically always present, although perhaps in an attenuated state. So far as I am aware, the conjunctival sac of the newly-born baby has not hitherto been investigated bacteriologically. This fact induced Dr. A. W. Sikes, pathologist to Queen Charlotte's Hospital, and myself to carry out a series of investigations upon the eyes of newly-born babies immediately after the cord had been cut, and before the eyes had been touched in any way. In twenty-four babies thus examined, the culture tubes were found to be sterile in eighteen instances, while in the other six saccina avanitica, flavo, and alba, a yeasty-like odium albicans, and an indefinite filmy growth of uncertain nature were found. It is important to notice that in no single instance was a pathogenic micro-organism demonstrated.

Vaginal discharges appear to be common accompaniments of pregnancy, especially in the lower classes. Investigations made by Cederchold (Medical Gazette, 1840, p. 382) for a long time as the year 1852 went to show that genital discharges existed in 137 out of 328 pregnant women. Haussmann (Die Bindecloth-Infektion der Neugeborenen, 1882) found purulent or mucous secretions in 249 of 250 pregnant women ! Oppenheimer (Arch. f. Gynak., xxv, 1883), among 108 in-maternal cases at the Heidenberg Maternity Hospital, discovered gonococci in 2700 per cent. Dr. G. C. van Schaick (New York Medical Journal, 1897, p. 598) has recently drawn attention to the frequency of gonococci in mar-

(a) C. Frankel (Zeit. f. Hygiene u. Infektionskrankheiten, 1899, Bd. 53) described in the same year three cases of pseudo-membranous conjunctivitis in children associated with the meningococcus. 

ried women suffering from leucorrhoea. He examined bacteriologically scrapings from the vaginal rute and neighbouring parts in sixty-five women, and found gonococci in 26 per cent. It is important to note that the women were all of fairly advanced age, and that no female whose position it made her infection a profes-

sional pursuit was knowingly included in the list. It is a somewhat curious fact that, from all I can learn, the experience of Queen Charlotte's Hospital shows a certain amount of it; and whereas any effort to combat it would be interesting to know whether this is the general experience of the London lying-in institutions.

Now the actual infection of the baby's eyes with gonococci may occur in three principal ways—(1) in the maternal passages, either before or during the act of birth; (2) almost immediately after birth; and (3) one or several days after birth. All the evidence at our disposal points to the second as by far the commonest mode of infection. The germ-laden discharge from the maternal passages clings to the eyelids and eyelashes, and, as a rule, is carried into the conjunctival sac either by the blinking of the baby or by the water, sponges, or towels used for the first bath. This mode of infection is spoken of as "primary." This being so, it becomes easy to understand that the disease, in most cases, makes its appearance within three days of birth, as shown in the following table:

<table>
<thead>
<tr>
<th>Cases</th>
<th>1 to 4</th>
<th>4 to 8</th>
<th>After</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uppenkamp</td>
<td>328</td>
<td>5884</td>
<td>3597</td>
</tr>
<tr>
<td>Von V. Hecker</td>
<td>100</td>
<td>5400</td>
<td>4600</td>
</tr>
<tr>
<td>R. Kistlin</td>
<td>32</td>
<td>5383</td>
<td>2666</td>
</tr>
<tr>
<td>E. T. Collins</td>
<td>32</td>
<td>7813</td>
<td>1250</td>
</tr>
</tbody>
</table>

In respect of this table, it should be noted—(a) that all kinds of infections, primary and secondary, are grouped together, and (b) that no attempt has been made to distinguish between gonorrhoeal and non-gonorrhoeal cases. It is improbable that a gonorrhoeal infection contracted soon after birth would manifest itself later than the fourth day, and the table shows that roughly two-thirds of all cases appeared within that period. Cases occurring after that time, if gonorrhoeal, are "secondary" inoculations, as from the articles used in the lying-in-room or from the fingers of the mother or attendants, or are caused by micro-organisms other than the gonococcus. A table is appended of my own cases in which the gonorrhoeal infection is distinguished from the non-gonorrhoeal cases:

<table>
<thead>
<tr>
<th>Cases</th>
<th>1 to 4</th>
<th>4 to 8</th>
<th>After</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gonorrhoeal</td>

<td>731</td>
</tr>
<tr>
<td>Non-gonorrhoeal</td>
<td>35</td>
<td>5714</td>
<td>3714</td>
</tr>
</tbody>
</table>

The mode of infection, first, is the aqueous humour, and then that within the maternal passages—must be assumed to have occurred when a baby is actually born with opthalmia or develops symptoms of the malady within a few hours after birth. A child, as well known, normally travels through the birth passage, and as such, the junction between the lids is watertight, morbid secretion cannot enter the conjunctival sac under ordinary circumstances. That could, however, readily come about during face presentations, the application of forceps, or by digital examinations on the part of the accoucheur. Some of the cases of ante-partum infection can be explained by a rupture of the membranes having taken place several hours or even days before the child was born, thereby allowing gonococci to reach the conjunctival sinuses.

(To be concluded in our next.)
INTESTINAL ANASTOMOSIS (a)
By E. STANMORE BISHOP, F.R.C.S.Eng.,
President of the Manchester Clinical Society and Hon. Surgeon to
De la Hey Hospital, Manchester.

My own experience of intestinal anastomosis is based upon twenty-two cases. I have no experience of lateral approximation, all my work having been end-to-end or end-to-side union. The choice of the method employed in any case is obviously of the utmost importance, for these cases are such that a second operation is practically impossible. Either the recovery, and no second attempt at union is required, or, if the general condition be such that with great rapidity so bad that any further interference is synonymous with death, probably on the table.

Beginning with Case 7, that of a young woman with a strangulated femoral hernia, the part actually strangulated was gangrenous at the time of operation, and was situated about the junction of the jejunum and ileum. It was excised, and the cut ends reunited without any bobbin by the Czerny-Lembert suture. Everything was satisfactory for the first few hours, then vomiting returned, and the patient died on the second day. Post-mortem distension of the proximal portion of intestine was found, with oedematous swelling of the returned edges of the gut almost entirely blocking the lumen. No leakage and no septic peritonitis, but some plastic adhesions to surrounding coils.

Case 18 was a case of pyocolulture for carcinoma united by simple suture without a bobbin in a woman, aged 38. The growth was not adherent, there were no enlarged glands, and the growth was absolutely limited and definite. It could easily be brought outside the abdominal wound, so that all the surgical procedure could be carried out in plain view. Wolff's operation was done, the upper part of the stomach sewn up by a continuous Lembert suture, the duodenum and a short segment of jejunum united by Wolfl's suture. During the operation pulse and respiration failed twice, but responded to transfusion, artificial respiration and strychnine hypodermics. Again, the result at first was most encouraging. She passed flatus the next day, and there was little or no chloroform vomiting. On the third day, however, the face was pinched, and there was some rigidity of the recti. This condition, however, improved, until, on the seventh day, sudden collapse occurred with increase in the area of the liver dulness. Death on the fifteenth day. Post-mortem, there was a large subphrenic abscess, communicating with the gastro-duodenal lumen, in which was an opening, with partially digested edges, just at the point where the vertical and circular lines of suture met.

Case 19 was one of incision of a part of the sigmoid flexure for carcinomatous sticture in a woman, aged 62. This was removed without difficulty, and the two ends easily united over one of my own bobbins, after permitting free exit of large quantities of gas and some faces from the distended descending colon. The patient bore the operation well, the bowels moved twice during the next twenty-four hours, and some food was taken; but from thirty hours after the operation when the last stool was passed, she began to retrograde. The descending colon evidently began to fill up again, and the patient died on the fourth day. No post-mortem was allowed, but the course of events pointed clearly to blocking of the bone tube in the large intestine by masses too large and too hard to be forced through. Duvejier and Graft have had similar experiences with the Murphy button.

Taking these three cases together they raise and illustrate, I think, the question of the use or rejection of artificial supports in the shape of decalcified sponges or other bobbins in this work. Now, the whole intestinal tract is not, for surgical purposes, of the same character in respect, not only in construction, but in the character of its contents, the latter difference being of very great importance. For instance, the fluid contained in the stomach, duodenum and jejunum especially, and for an undetermined extent in the ileum, has certain chemical and digestive properties, these become less accentuated in the lower ileum, and are absent in the cæcum, colon, sigmoid, and rectum. When the bowel ends have been sewn together, the material thrown out as a rule is too small to do to any extent to the action of whatever happens to be contained in the lumen of the gut; if the suture is weak at any point, this exposure is, of course, more likely to occur. Peristaltic action is more consistent in the upper part of the small intestines than in the large, owing to the liquid character of its contents. The openings through which the suture passes are therefore exposed to a more frequent repetition of strain and alteration in the small intestine than in the large, however, is compensated to a great extent by the more severe strain which they have to resist in the latter. It is, however, especially the liquid and pepto-chemical character of the contents of the stomach and small intestine which constitutes the main danger against which some protection of the line of union is needed, and this is supplied by the bone bobbin if properly made. The post-mortem appearances in Case 18 showed not only a weak point in the suture, but the edges of the opening at this point had a semi-digested look, and I have no doubt that this process rendered any attempt that otherwise might have been made by plastic adhesions to limit the gastric contents, even if it had no part, as I think it had, in starting the lesion.

On the other hand, the lumen of the bobbin in the sigmoid flexure undoubtedly became blocked by hard fecal masses, which might have passed through an intestine which was flexible, such as would be left by a simple suture, but could not be driven through a rigid tube such as is formed by any apparatus in this situation.

Another danger of simple suturing in the small intestine is well shown by Case 7, in which Czerny-Lembert suturing alone without any protective apparatus resulted in an oedematous condition of the inturmed gut, and consequent stenosis, ending in death. The danger from any such oedematous swelling in the large intestine, should it occur—all the cases noted have been in the small—on the other hand, is not likely to be great, owing to the greater calibre of that portion of the gut. I think, therefore, that the facts point in favour of the use of such appliances in the stomach and small intestine, but not markedly against their use in the large.

If bobbins are to be used in operations on strangulated hernia it becomes a matter of some difficulty to choose between the large number which have been devised. I have here a large and fairly representative collection. Murphy's button occupies a place by itself, the most devised, perhaps most quickly applied, and when properly made gives a rapid, safe, and reliable union. It was originally devised to save suturing entirely, which is the manœuvre which occupies most of the time expended. Many surgeons, however, prefer to place a row of sutures outside, and then its superiority in point of rapidity of application is not very apparent. It has, moreover, certain very objectionable points. It is heavy, and has produced kinking of the bowels. It acts by producing spachelation of the parts included in its grip.

I am able, by the kindness of Dr. Jacob Frank, of Chicago, to exhibit here to-day his coupler, which, so far as I know, has not previously been shown in England. This, you will see, is based upon Murphy's pattern, but is intended to evade some of the objections to the use of the latter. Two supports in the form of the Murphy button are here replaced by absorbable decalcified bone, and the metal stem and spring are represented by a rubber tube, the two ends of which are sewn to the shoulders. The button slips over the shoulders, and confined between them and around the central tube, as in the Murphy button, by purse-string sutures, the shoulders being pulled apart to permit of this. When they are so a part of the natural resilience of the rubber tube clamps the intestinal ends between the two bone ends. When these

(1) Abstract of Paper read before the British Medical Association at Swansea, August, 1903.
parts become softened the attachments of the tube loosen, and the tube itself passes down the intestine. Being smaller than its lumen and compressible, it is not likely to cause any later obstruction by its presence, and the bowels are not infrequently digested until they pass easily. I have no experience of its use, but it is highly spoken of by American surgeons. The only difficulty which I have found in experiments upon the cadaver is in slipping it into the second intestinal segment whilst maintaining traction upon the bobbin, but that, no doubt, is due to my own unfamiliarity with the appliance. With it I show also a very useful instrument which I have also devised, an entero-enterotomy, by which the inside of the bowel can be determined, and a suitable size of bobbin be chosen.

The ideal bobbin should be easily introduced, it should be of such a shape that the tightening of the purse-string sutures in the ends of the gut automatically approximate them, it should give a solid and reliable support, it should adequately protect the line of union from all possible contact with the contents of the lumen of the gut, and it should place the ends in such a position as to render any further suturing easy, rapid, and even. The same form is not likely to suit all positions; for instance, the best form for end-to-end union, as in enterotomy, is not likely to be the best for an end-to-side union in ileo-colostomy or gastro-enterostomy. For ordinary enterectomy I have endeavoured to fashion a bobbin which should possess the advantage which is to be found in Allingham's. The construction of the shape of that purse-string is to be remembered the opposition which I encountered in 1887 when I first proposed such a method. Since that time, however, Halstead has demonstrated admirably the necessity in all suturing of obtaining a firm hold upon the submucosa, the only portion of the wall of the intestine which is capable of resisting the effect of peristalsis in causing the yielding and tearing of sutures which has attempted to carry out this principle upon intestines in the mortem or room or to secure this layer upon living animals will acknowledge that it is practically impossible to be certain that his thread does not penetrate one of Lieberkühn's follicles, and does not therefore communicate with the intestinal lumen. If Halstead's suture is safe, and numberless cases in various hands have testified to this safety, it necessarily follows that the danger of such communication has been greatly overrated. If we add to this the old well-attested fact first pointed out by Thompson, and confirmed by Travers, Benjamin Bell, and Dupuytren, that the submucosa is quite as firm as the serosa, that the entire thickness of the bowel, however placed, unless absorbed in situ, which few are, sooner or later find their way into the lumen of the gut, and are thrown out of the body by that route, we shall agree, I think, that there is no reason against through-and-through suturing, if other advantages are to be gained by it. Such advantages are, first, the certainty of perfect apposition during the period of union, and, secondly, such a union that tearing away by the action of the peristalsis is practically impossible.

M. G. Connell, in 1892, and C. N. Dowd, in 1902, have both introduced sutures which, like my own, penetrate the entire thickness of the colon, and have been published both by themselves and others proving their entire safety. Indeed, it may now fairly be said that the unsafe suture is the one which yields before union is complete, either because of weakness, or more often because it grips only tissues, such as peritoneum and muscular layer, which cannot be depended upon to resist the strain of peristalsis.

But whilst this may be said of all peristing sutures, this cannot be said of the peritoneum. As the mucous tissues in the large intestine can be detached by the fingers nothing but a new suture can be used; these supports are modelled upon these various moulds, and are baked upon them. When baked the moulds are sprung out of them, and they are then used in the same way as those made of decalcified bone. As they commence to soften and disintegrate from the moment of use, they will not produce the obstruction which follows the use of the bone tube, and therefore might with safety be used in situations where the others would become blocked by hard fecal masses. There can be no doubt that the presence of some support enables the surgeon to apply his sutures more evenly, and therefore more safely, but the very transiency of their presence contra-indicates their use in the small intestine, where they would give but little protection, and that for too short a time.

It may be noticed that I have said nothing of purse-string plates, or of their representative in potato, turnip, raw hide, etc., and that any set can be included in this collection. The union formed by these appliances is ungainly and awkward. The bowel so united forms a large unwieldy mass which is difficult to return to the abdominal cavity without an otherwise unnecessarily large opening, the prospect of adhesions of the cell containing them to surrounding coils, and consequent later obstruction, is increased, and as far as I can judge from current literature they have had their day, and are being wisely given up.

Modern methods of suture may be divided into those which penetrate the whole thickness of the wall and those which do not penetrate the entire wall. For many years as a surgeon I have had experience of obtaining a holy horror of the former. I am not sure that this horror does not even yet prevail in many minds. All kinds of dire results were supposed to follow the penetration of the submucosa. The shape of the suture was much the same. I remember the opposition which I encountered in 1887 when I first proposed such a method. Since that time, however, Halstead has demonstrated admirably the necessity in all suturing of obtaining a firm hold upon the submucosa, the only portion of the wall of the intestine which is capable of resisting the effect of peristalsis in causing the yielding and tearing of sutures which has attempted to carry out this principle upon intestines in the mortem or room or to secure this layer upon living animals will acknowledge that it is practically impossible to be certain that his thread does not penetrate one of Lieberkühn's follicles, and does not therefore communicate with the intestinal lumen. If Halstead's suture is safe, and numberless cases in various hands have testified to this safety, it necessarily follows that the danger of such communication has been greatly overrated. If we add to this the old well-attested fact first pointed out by Thompson, and confirmed by Travers, Benjamin Bell, and Dupuytren, that the submucosa is quite as firm as the serosa, that the entire thickness of the bowel, however placed, unless absorbed in situ, which few are, sooner or later find their way into the lumen of the gut, and are thrown out of the body by that route, we shall agree, I think, that there is no reason against through-and-through suturing, if other advantages are to be gained by it. Such advantages are, first, the certainty of perfect apposition during the period of union, and, secondly, such a union that tearing away by the action of the peristalsis is practically impossible.
suture, a diagram of which was shown. After recovery they were killed by chloroform at various dates—fourteen days, one month, two months, &c., from the date of excision. As your will see, at each succeeding date, as the sutures separate they carry with them more and more of the obstructive ring, until the internal surface of the bowel becomes once more smooth and even.

There are two reinforcing sutures which are worthy of attention. Probably the suture most used is the Lembert, but it does not appear that its reversed form, in which the knots become as they are drawn tight, has found as much favour as it would appear to deserve. (Both were shown in another diagram, and the nearer appearance of the result in the reversed suture was very evident.)

The other suture is one introduced by Cushing, and is called by him the right-angled suture. This also buries itself as it proceeds, and therefore greatly decreases the risk of post-operative adhesions. It is, however, a continuous suture, and is probably improved if knotted as Dowd suggests, at every third or fourth insertion. It is practically Gely’s suture, only made with one needle instead of two.

Ease, regularity and rapidity in suturing is greatly increased when such sutures are used, by the employment of Allis’ basting forceps.

With regard to the advisability or otherwise of preliminary colotomy when portions of the large intestines have been removed for malignant disease, it is evident enough that instead of one operation the patient has to face three: the colotomy itself, the excision of the affected portion of gut, and the subsequent closure of the colotomy opening, as of which must be carried out at separate times; but the advantages gained are sufficient, in my opinion, to entirely overbalance this. In some cases, as suggested by my friend Mr. Wilson, of Manchester, when the meso-colon or meso-sigmoid is long enough at the point of constriction, two of these operations might be combined. The growth itself might form the apex of the portion of gut withdrawn at the preliminary colotomy, especially if seated in the sigmoid. After the surrounding union was firm, that is, within forty-eight hours, it might be removed along with a sufficient amount of healthy bowel, and when everything had again become normal, so far as contraction of the previously distended proximal extremity was concerned, the two ends might again be freed from the anterior wall and united. Several things, however, would have to be favourable in order to accomplish this. The location of the obstruction must be known. It is, no doubt, the experience of others, as it has been my own, that many of such cases only come to the surgeon when obstruction has been complete for some days, when the abdomen is uniformly distended, and the situation of the growth can only be surmised. Then the growth must not adhere to parts around, nor should there be any enlarged mesenteric glands. The meso-sigmoid—or it is in this region that most of the growth capable of treatment in this way are situated—must be sufficiently long not only to permit of the exit of the intestine affected, but of a sufficient amount on either side to permit of the section being carried far enough from it. It would not be possible for all these favourable circumstances to be found in many cases; and therefore it will still be necessary, in most instances, to face the three operations. The advantages obtained are, in my opinion, very great. Preliminary colotomy transforms a patient who, with tensely distended abdomen, is in a very unfit state to bear any operation but the most rapid, into one who can safely stand the necessary manipulations and be unconscious. In some cases the abdominal side of the growth can be examined, so that a better idea of what will be required at the major operation can be obtained beforehand. This was done with great advantage. If the suture is well made and the tissues themselves can be made clean between division; they can be kept so after it, and only when the union is firm and reliable need they be called upon to resume their normal functions.

For the sake of clearness, allow me to recapitulate the points to which I have referred.

1. It is suggested that the terms "fundal point" and "fundal line" will be useful for purposes of description as defining that portion of the intestine which is opposite to the mesenteric insertion.

2. The use of decalcified bone bobbins is advisable in operations for union in the gastric region and the upper part of the small intestine, mainly because they act as a protection during the early stages of union, and because the intestinal contents in these segments are liquid, and possess certain chemical and digestive properties, from which the line of union in these regions need be protected.

3. That the use of such appliances is doubtful in the lower small intestine, and is absolutely contra-indicated in the large, mainly because of the solid semi-solid nature of their contents. That this objection does not apply to Wackerhagen’s washers, which, indeed, are to be restricted to those segments of the gut.

4. That in choosing a mode of suture, that one is to be preferred which gives the most perfect security against leakage in yielding to the peristaltic strain, which exposes itself the least, and so minimises the irritation and consequent adhesion of surrounding peritoneal surfaces, by which later risk of latent perforation, and which removes the inevitable diaphragm formed by the necessary inturning of the bowel ends, so as to leave a smooth internal surface.

5. That the use of forceps, such as O’Hara’s, or the preliminary crushing of the intestine, as by Cloward or Vidal’s methods, all of which are based upon the idea of producing sphacelation of the incised edges of the gut, are of very doubtful value, are associated with increase of shock and ulceration of later perforation, and should not be preferred to simple suturing or to suture over some absorbable and protective appliance.

6. That in cases where a neoplasm or other obstruction has to be removed from the large intestine, the prospects of success are greater if a colotomy above the seat of the obstruction can be previously carried out.

THE SIGNIFICANCE OF LEUCOCYTOSIS IN APPENDICITIS.

By Drs. MAURICE CAZIN and EDMOND GROS, of the Paris Hospitals.

Much attention has been devoted during the last two or three years to the clinical importance of leucocytosis in appendicitis. During the recent debate at the Surgical Society of Paris, the majority of speakers, although agreeing that immediate intervention is necessary in all cases in which there is suppuration, were insist upon the difficulties that the diagnosis of suppuratio presents. It appears from the recently published works on this subject that by merely counting the blood corpuscles very important indications in regard to the diagnosis, and to the exact course of the disease, may be obtained, especially with respect to abscess formation, the increase in the number of leucocytes being associated, as shown by Professor Hayem long since, with circumscribed suppuration, following an acute inflammatory attack.

We will intentionally omit dealing with the claims advanced on behalf of Ehrlich’s iodine reaction on the white corpuscles of the blood for the differential diagnosis of the various phases of appendicitis. The few examinations which we have been enabled to make on this subject do not allow of our forming a trustworthy opinion of its value, since its results have been observed in various infective diseases without its having been found possible to define the limits which separate the normal from the pathological state. It is idle to hope that the results of examination of the blood will bring about an agreement between the advocates of surgical intervention and those who are in favour of systematic abstention. The former will, indeed, probably despise this method.
of investigation as an indication of the necessity for operation or, otherwise, as they always intervene as soon as they diagnose peritonitis. Why, however, should they not take this into account, at any rate in doubtful cases, in which the examination of the blood gives more precise information than either pulse or temperature? But, after all, it is the abstainers who are most to blame for neglecting the research of leucocytosis, which alone can give a positive operative indication, when all the other symptoms are ill-defined, a fact of which we have been able to convince ourselves in several instances, and which is confirmed by those who resort systematically to the procedure in all cases of appendicitis. They all report numerous cases in which the clinical data provided by the examination of the blood hold greater importance than the other symptoms, and have suffered to decide in favour of operation.

Before discussing the significance of leucocytosis in appendicitis it may be well to describe briefly the procedure which we employ, which, simple though it be, enables any practitioner, however unfamiliar with the use of the microscope, to promptly estimate the proportion of white corpuscles in the blood.

We use Hayem's hematometer with a movable planchet. Blood is collected without the usual precautions by pricking the finger, preferably on the dorsum. We employ a special pipette to hold 20 cubic millimeters of blood, which enables us to prevent coagulation, which so frequently takes place with the small ordinary pipette of 2 cubic millimeters. After having carefully wiped the end of the pipette to remove any excess of blood, it is emptied into a test tube, containing 500 cubic millimeters of a 5% solution of acetic acid. The acid destroys the red globules, and renders the nuclei of the leucocytes very visible. Shake the mixture well, so as to make sure of the proper distribution of the white corpuscles. The pipette used to measure the solution contains 6 cubic millimeters; consequently, only 494 cubic millimeters of the solution will be expelled, to which is added the 20 cubic millimeters of blood.

The calculation which allows us to estimate the number of leucocytes contained in a cubic millimeter of blood is based upon the answers to the following questions:—How much blood is there in a cubic millimeter of the mixture just described? This mixture contains 404+20=514 cubic millimeters; consequently, only 494 cubic millimeters of the solution will be expelled, to which is added the 20 cubic millimeters of blood.

How much blood is there in each square of the ruled hematometer? Now each square corresponds to a cubic millimeter, e.g. to 1 c.c.m.m. of the mixture, be examined. Now we know that 1 c.c.m.m. of this mixture contains 20:514 c.c.m.m. of blood. Therefore, in o'008 c.c.m.m. there is (20*0.008)=514, or 1:3,212, or, approximately, 1:3200 of one cubic milliliter. The leucocytes found in one square of the hematometer belong therefore to 1:3200 c.c.m.m. of blood.

If, for instance, one square presents 5 leucocytes, it follows that 1:3200 c.c.m.m. of blood contains 5 leucocytes and, consequently, 1 c.c.m.m. contains 3,200 times more, or 5x3,200.

But when several squares are successively examined in the same preparation, the same number of leucocytes is not found in all. The white corpuscles of a certain number of squares must, therefore, be counted, and an average taken of the numbers obtained. If, for instance, by displacing the preparation so as to examine the drop of liquid from side to side 25 leucocytes have been found in a total of 52 squares, the conclusion come to is that each square contains on an average 285:52 leucocytes, and that the number of these per cubic millimeter, is, therefore, equal to (285*52)=15,000. M. Hallopeau has devised a simple plan to facilitate the calculation, viz., to count the corpuscles of 32 squares. If, in these 32 squares, we find a total of 314 leucocytes, we immediately come to the conclusion that each cubic millimeter of blood contains 314*3200=1,014,400, or, by simplifying, 314X100=31,400.

By this process, the examination of blood for leucocytosis can be effected in a few minutes. What we wish to point out is that the count must be done several times over, taking the average of several evaluations, each of 32 squares. At least two numerations must be made, and if for the two the ratios of two results which do not agree, are obtained, it will suffice. When, on the contrary, there is a marked difference, it is necessary to repeat the examination several times, for the oftener this is done, the more correct the average is, and the nearer to the true number.

For those who are not very familiar with the microscopic examination of blood, instead of employing the solution of acetic acid, which destroys the red corpuscles, we may stain with gentian violet, which brings the leucocytes into prominence. This method, however, takes much longer.

Dr. J. B. Deaver has rightly insisted upon the necessity of careful observation, upon which depends the value of the procedure. It is obvious that careless observation will altogether change the result, for simple as is the process some practice is indispensable for accurate estimation. It is a good plan to examine the blood of a person, either healthy or sick, at different times, over a period of time, making a fresh prick each time—the results obtained by calculation must be almost identical before anyone can consider himself sufficiently expert to undertake the enumeration of the leucocytes in a case of appendicitis.

In the adult male the number of white corpuscles in the blood in a normal state averages 7,500 per cubic millimeter (Malassez); it varies from 5,000 to 10,000 according to Curschmann; from 7,000 to 9,000 according to Kittner; from 4,000 to 11,000 according to Wassermann. In a child the proportion is usually higher and less constant than in the adult. Speaking generally, we may take it that any number over 10,000 per cubic millimetre testifies to an increase of the white corpuscles.

In spite of the generally received opinions, leucocytosis is usually present from the onset of the attack of appendicitis, even in the absence of suppuration. Curschmann is very positive on this point, and considers it fully demonstrated that, in the majority of all the forms of peritonitis, from the very beginning the number of leucocytes is increased; in slight cases this increase is usually not very pronounced, the number of leucocytes varying between 10,000 and 15,000, but sometimes reaching between 19,000 and 20,000, as we have ourselves observed the day after the third day, even in the absence of localised suppuration. The increase, however, is very evanescent, and the proportion soon falls from 20,000 to 10,000, and even to 0,000. These data concord, moreover, with the experimental results, published long since by Schulz, who showed that, in the dog, simple irritation of the peritoneum by an aseptic incision, through the linea alba, followed by an immediate closure, determined occasionally very marked leucocytosis amounting even to 54,000 leucocytes per cubic millimeter of blood. Wassermann's observations established the fact that laparatomy for the removal of the appendix during a period of quiescence is usually followed by leucocytosis; the proportion of the white corpuscles being quite normal and varying between 7,500 and 8,500 before the operation, raising to 14,000, 14,000, or even 30,000, after it, ultimately falling to normal, without there having been the slightest suspicion of sepsis.

It is therefore demonstrated that even a septic irritation of the peritoneum determines leucocytosis. Every attack of appendicitis, accompanied by the least peritoneal reaction, is followed by an increase in the number of leucocytes, except in certain hypotoxic forms, when the defensive reactions of the organism have not had time to take place. Numerous observations of the type corpuscles cannot therefore afford us any assistance at
the beginning of an attack of appendicitis so far as the diagnosis of the form; and it is only by methodical enumeration repeated morning and evening that it is possible to state with any degree of certainty that the condition of the illness is forming. It follows that on the first or even on the second day operative measures still constitute the only sure means of averting the always possible fatal termination, and the blood count tells us nothing as to whether the course of the illness will be mild or serious.

But if leucocytosis cannot be employed to diagnose the appendicitis, at the onset of the attack this sign should nevertheless be sought for, if only to establish the nature of the affection in doubtful cases. Indeed, any increase in the number of white corpuscles, however slight, favours the diagnosis of appendicitis, and allows us to discard all the other affections characterised by hyperleucocytosis, or not associated with any modification of the number of leucocytes.

As we have just pointed out, single enumeration, practised at the onset of an attack of appendicitis, teaches us nothing in regard to the particular form which we are dealing with. But it is quite different when we make repeated enumerations once or twice daily.

It may be affirmed in a general way that in the mild cases ending in resolution the proportion of leucocytes does not exceed 20,000 to 25,000, such increase, moreover, being very fugitive.

We have collected notes of seventeen mild cases, ending in resolution, in which the enumeration of the white globules was carried out systematically; six times only did the number exceed 15,000; twice it reached 15,000, and three times it varied between 20,200 and 22,900.

We may therefore admit, with Curschmann, that, if the number of leucocytes only undergoes slight increase, in the majority of instances the course of the illness will probably be mild and comparatively short, and that, if the number during several consecutive days remains comparatively low, or undergoes a notable but ephemeral increase (20,000 to 25,000), one may almost certainly foretell resolution, even when the temperature or its fall fail to justify such a prognosis.

If there be one point upon which all surgeons appear to agree in regard to the treatment of appendicitis it seems to be upon the necessity of prompt intervention in all cases of abscess. Now, if surgeons admit almost unanimously the necessity of evacuating all collections of pus of appendicular origin, they also agree in recognising the same necessity which actually occurs in the diagnosis of abscess. It is in this respect that Hayem's sign truly deserves to become indispensable in general practice, since this sign alone permits of the early diagnosis of abscess, in cases where the temperature or its fall fail to justify such a diagnosis.

As has been conclusively proved by Curschmann's demonstrations, the curves provided by the enumeration of the leucocytes, systematically repeated, have a value far superior indeed to the temperature, persistent hyperleucocytosis constituting, so to speak, a constant and invaluable sign of suppuration, while the fever may be slight and even sometimes nil, in spite of very extensive suppuration. Wasserbauer, moreover, considers persistent hyperleucocytosis to be pathognomonic of the formation of an abscess, in regard to the precise moment at which the physician, having reached the end of his tether, declines all further responsibility, and hands the case over to the surgeon.

As we have said initial leucocytosis in appendicitis, in spite of a very high temperature and violent local pain, does not furnish any definite conclusion in regard to the future course of the illness, the enumeration of the corpuscles must be made momentarily to a comparatively high proportion—viz., 20,000 or 25,000 white corpuscles per cubic millimetre. When, on the contrary, the number of white corpuscles undergoes a considerable and permanent fall, we have this pess with the persistence of suppuration, whatever other symptoms may be present.

Personal observation has convinced us of the truth of this statement. In one case, that of a child, aged 5, at the beginning of the third day of appendicitis, with a temperature of 40° C. and a pulse of 80 only, the enumeration of the white corpuscles gave 8,500. On the fifth day the fever had dropped, and the general condition improved. On the sixth day, after the examination of the blood, which had been made for two days, indicated a leucocytosis proportion of 31,000 per cubic millimetre, although the rectal temperature was still 38° C., and the pulse was only 80. Locally there was only a very moderate inflammation, and but slight swelling. The patient was immediately operated upon, and a retrocecal abscess of the size of a hen's egg was evacuated, after which she began to recover forthwith. This case is particularly interesting, as showing the precision with which the examination of the blood allows of the diagnosis of appendicular abscesses, even when the physical signs are uncertain and little marked, and this when the temperature and the pulse are normal or nearly so.

Professor Dieulafoy has rightly insisted on this deceitful lull, which often follows the violent and painful onset of appendicitis, during which the peritoneal lesions do not cease to develop in all their rapid and serious manner, in spite of the apparent benignity of the symptoms. Now this lull cannot deceive us if the enumeration of the white globules of the blood is systematically practised, for, as has been shown, this enumeration suffices to indicate for certain the existence of suppuration, which no other symptom would authorise one to suspect.

There does not exist, let it be well understood, a leucocytic formula which can be considered to correspond, even approximately, to a mean of the number of white corpuscles in cases of suppuration of appendicular origin. The defensive reaction of the organism of which leucocytosis is merely a manifestation obviously varies according to many circumstances, and under certain conditions is very difficult to define; it is pointed out that, on the other hand, the examination of the blood is less subject to any error than that which takes place in the mild forms, ending in resolution, in which the leucocytic rate varies between 10,000 and 15,000, and does not reach or exceed 20,000, except epidemically, in the case of abscess, the leucocytic rate remains about 20,000 very persistently, and more often increases progressively until it reaches a point never met with in cases in which there is no suppuration—viz., either 30,000, 35,000, 40,000, and 45,000.

All the published observations show that there is no relationship between temperature and leucocytosis; the latter may be very high, whilst the temperature is normal, or thereabouts. On the other hand, the careful study of the numerous examinations of the blood that have been made during appendicitis prove beyond doubt that it is leucocytosis, and not to temperature, that we must in case of disagreement, refer our decision as regards the necessity for operative intervention.

We are in a position to affirm that in all cases in which leucocytosis has led to early diagnosis and evacuation of the abscess, even when other symptoms were wanting, recovery has followed, precisely because the examination of the blood precipitated the operation, which one was hesitating to perform. In one case quoted by Jauerbruck operation was delayed, although the leucocytosis was high, and the time was decided upon at a time when the leucocytes had reached 40,000, it was too late to be efficacious. We have also observed a case in which the enumeration of the blood was perfectly satisfactory to the surgeon, and in which the presence of an abscess, in spite of a rectal temperature of 37° C., and a pulse of 90, and a satisfactory general state, we proposed immediate operation, which was accepted. The patient was cured.

The existence of generalised peritonitis, proved by the examination of the peritoneal cavity, with its evident fatal results, has made us take it as proved that the enumeration of the white corpuscles is of primary importance as regards the diagnosis of abscesses, and that any physician who has to deal with a case of appendicitis, in which such a condition exists, and who wishes to claim himself justified in postponing surgical intervention,
cannot conscientiously omit to have recourse to the examination of the blood, often repeated, if he does not wish to expose his patient to the certainty of a tardy operation, which by this method might have been performed in time to bring about recovery.

In spite of the unanimous opinion of the surgeons who have verified Curschmann's results, the M. Graven of New York, in the new edition of his treatise of haematology, makes some reservations as to the value of leucocytes in the diagnosis of abscesses. He admits, and this, indeed cannot be denied, that the result given by the examination of the blood in regard to the increase of the white corpuscles may help to guide the diagnosis in a very satisfactory manner, and for that very reason affords one of the clearest indications for surgical interference. But, he adds, a negative result is in no way absolutely incompatible with abscess formation. Now, it has never been claimed that this sign is to be considered pathognomonic of appendicular suppuration. It is sufficient for this enumeration to be taken into consideration that it never deceives when the leucocytic rate indicates the presence of an abscess. The operation is performed without delay, and saves the patient. On every occasion on which this method has been systematically followed, and has given a positive result followed by immediate intervention, the surgeon has found an abscess, and has cured his patient. It would be greatly to the advantage if one of the symptoms of equal importance existed as regards appendicitis.

It is none the less true, however, without in any way reducing the certainty of positive results, that the absence of marked leucocytosis has been noted even when suppuration existed, but the negative result seems to have been obtained in only two cases of very different nature. In a first series of observations we have to do with non-encysted suppurations in certain cases of diffuse hypertoxic peritonitis in which the defensive reactions of the organism are lacking; the leucocytic rate remaining slightly raised, or even below the normal.

In a second series, we have cases of encysted abscesses persisting after the acute symptoms, and in these leucocytosis may also be wanting. These abscesses are shut in by a thick fibrous wall, which does not allow the reabsorption of toxins from the suppurating cavity. Now it is evidently the reabsorption of these toxins and their dissemination through the circulation that determines leucocytosis. This absorption takes place, the more readily the more recent the abscess formation, on an account of the structure of the wall. It may be nil in the case of an old encysted abscess with fibrous walls.

We have mentioned that suppuration may take place without leucocytosis in certain cases of diffuse hypertoxic peritonitis. Only a limited number of observations are available of leucocytosis in diffuse peritonitis, ending rapidly in death. Curschmann, however, believes that in cases of generalised peritonitis the leucocytic rate, at first greatly increased, comes rapidly down to the normal and even below.

Rieder, Küttnar, Kühn, and Coste have recorded the absence of leucocytosis in cases of acute peritonitis in dogs, in which the organism had no time to react.

Da Costa published twelve observations ending in death; out of this number leucocytosis failed twice only, the leucocytic rate not having exceeded 6,000 in 11,000; in the other ten cases the mean was 19,400, with a minimum of 14,200 and a maximum rising to 58,900.

This absence of leucocytosis, notwithstanding the gravest clinical indications, justifies any serious prognosis, for it points to a considerable decrease in the resistance of the organism. When, on the contrary, it does exist, in cases of generalised peritonitis, leucocytosis indicates a defensive reaction, which renders operation comparatively favourable. Thus, in the case of a patient suffering from generalised peritonitis, and treated by immediate intervention, M. Küttnar has found as many as 50,000 white globules, and operated a cure.

M. Wassermann emphasises the fact that in a case in which the operation showed the existence of diffuse peritonitis, leucocytosis was in amazing opposition to the comparatively trivial clinical signs, there being an abdominal facies, but no fever and only the abdomen very slightly distended and painful. It may be added that, as early as the morning of the second day, on account of the persistence of marked leucocytosis, the M. Graven's results, M. Curschmann has recorded a very typical instance of this. The patient was a student operated on the fifth day. In this case the appendix was amputated after an abscess had been opened. On the following days, the leucocytic rate did not show any tendency to decrease, and in presence of this persistent leucocytosis, in spite of a comparatively low temperature, a second operation was performed, when an abscess in the pelvis was evacuated. This time the number of white corpuscles fell immediately to normal.

We had an opportunity of observing a similar case in a young man, with 27,000 leucocytes per cubic millimetre, in whom the appendix was opened, and suitably drained; yet in spite of this, not only the leucocytosis did not decrease, but, on the contrary, it continued to increase to a marked extent, and the patient died before a further intervention could be practised.

Enumeration of the white corpuscles in appendicitis is, therefore, of great value as an indication for operation, at any rate, in a certain number of doubtful cases. Indeed, as stated by M. Curschmann, though it may appear excessive to advise the daily examination of the blood in all cases of appendicitis, in view of the fact that often the evolution of the disease can be ascertained without this manner of investigation, it is one of the less certain that, in doubtful and obscure cases, this method really gives a wider scope to our diagnosis, and may render valuable service.

NOTES ON A CASE OF CONTUSION OF THE ABDOMINAL WALL FROM THE KICK OF A HORSE DOUBLE RUPTURE OF THE INTESTINE—LAPAROTOMY.—CURE. (a)

Under the Care of Prof. Bogdanovici, of the University General Hospital, Bucharest.

[Specially Reported for the Medical Press and Circular.]

During the night of January 22nd, 1903, a young man was admitted to hospital for M. Racoviceanu. He was 19, and was suffering from the kick of a horse. He was struck at the point of the seventh rib on a line with the left nipple. The blow caused him to faint and fall, and on being revived he complained of intense abdominal-thoracic pains. He vomited what food was in his stomach, and felt easier. On the following morning he felt easier, and looked better. He had no increase of temperature, and there were no symptoms of peritonitis, though it was noticed that his respirations were slightly quickened; at the extremity of the eighth rib there was an ecchymosis and an excoriation, and pressure produced a violent pain. The whole abdominal wall was sensible to palpation, which provoked a certain amount of resistance. Absolute rest
was enjoined, and ice placed on the abdomen. In the evening the temperature had risen to 104° 4 F., and his pulse was 120, hard and throbbing; his face congested; his tongue dry; and he complained of severe pains in his abdomen, especially in his right iliac fossa, withal these symptoms he had not. On palpation of the edge of the tumour, and no vomiting. The urine was somewhat reddish. The following day the patient expressed himself as feeling better; the pulse 90, and regular, and the temperature had fallen to 99° 8 F., but the epigastric region was still tender and the abdominal muscles became tense on palpation; these symptoms decided M. Racoviceano to make an exploratory laparotomy under chloroform. The abdomen was opened and a false membrane, which covered two intestinal perforations, which were situated face to face on the mesenteric border of the bowel. The rents were about the size of a sixpenny piece. The intestinal wall in the neighbourhood was very brittle, which caused it to retract from suturing the openings. With sterile compresses we mopped up all the liquid contained in the abdomen and afterwards washed out the peritoneal cavity with artificial serum and brought the wounded intestine into place by the apparatus of Mikulicz. The intestines were sutured, the abdominal wall closed, and ice placed over the wound.

No food was given for four days, but subcutaneous injections of artificial serum were administered daily, 3,000 grammes on the first day, 2,000 grammes on the second day, and 1,000 grammes on the third day. During those days the patient had some light peritoneal reaction, with bilious vomiting; the pulse ranged from 90 to 105. On the 19th of January the temperature was 96° 4 F. to 101° 5 F. On January 22nd the bowels acted naturally. Day by day the man improved, and was convalescent at the end of January. It is remarkable that the only external signs in this case were ecchymosis, which occurred on a situation considerably removed from the position of the intestinal injury, which goes to prove that the injury is not caused by the sudden compression between the striking force and the vertebral column. Again it is remarkable that for thirty hours after admission the patient was free from any sign of peritonitis; he felt so well that the suggestion of an operation to him came as a surprise, although the abdominal cavity had already been filled with artificial liquid, and that intestinal movements were well advanced in the peritoneum.

Withal the patient had some faint evidences of mischief, evidences very likely to be overlooked—the increased strength of the respiration, the elevation of temperature, which commenced at the sixteenth hour. But for the first twenty-four hours there was no characteristic sign of a grave intestinal injury, even though the muscles became tense on palpation, and there was pain on pressure. Between the twelfth and the fourteenth hour vomiting and an elevation of temperature occurred, symptoms which Dubuyardoux considered called for surgical intervention. It is difficult to interpret the symptoms in this case of abdominal injury, where the anterior wall is intact. Dubuyardoux, of Bilda, considers that the pathognomonic symptoms of injury to the intra-abdominal organs are a crimson colour of the skin over the malar bones and of the nose; a sub-icteric coloration of the sclerotic and respiratory movements of the aëre nasi; frequent and anxious respiratory action of the thorax; an increase of temperature; tension on palpation of the anterior abdominal muscles; and vomiting. All these symptoms have, however, been observed in other diseases. Demosia, at the Congress of Surgery at Paris in 1897, insisted on the value as a sign of intra-abdominal injury on the mobility of the anterior abdominal muscles. He looked on it as a definite symptomatic characteristic of an injury to one of the hollow organs. At the same Congress, Le Dantou asserted that the hyperesthesia of the abdominal wall was a symptom that demanded laparotomy. But those who systematically study the symptoms for some pathognomonic sign or group as Hartman shewed when addressing the Congress of Surgery at Paris on one of M. Manclaire's cases, in which hyperesthesia was present. Hartman classifies contusions of the abdomen into those which have contraction of the muscle tissue of the abdomen and those in which seventy-seven patients had had contractions of the abdominal walls: one of them refused to allow an operation and died soon after of peritonitis consequent on an intestinal rupture; the other nine had injuries of the small Sciatic nerve. Of the seventeen patients who had no muscular contraction, they all got well without surgical intervention, though two of them had hæmaturia, probably due to some renal injury.

The Out-Patient Departments.

GREAT NORTHERN CENTRAL HOSPITAL.

Medical Cases under the Care of H. W. Syers, M.A.
M.D.Cantab.

I.—A woman, aged 23. She complained of severe pain in the right hip and thigh, which had been present for two days before being seen. The pain was of a cutting burning character and prevented sleep. A rash had also been observed.

Dr. Syers remarked that in cases such as this it was not unusual in old people to find that the lesion was zoster, but that in young persons such a pain as was complained of in the present instance was not a marked feature of the malady. Nevertheless, an examination proved the case to be one of zoster, the eruption appearing to follow the course of the small sciatic nerve, and extending to the right labium, where a very prominent patch of vesicular eruption was visible.

A soothing ointment and an opiate draught were ordered, but the pain continued extremely acute, so much so that the patient sought admission. She was treated with a morphia injection, but even this did not induce sleep. With the full evolution of the rash, the pain disappeared. Such extreme pain is very unusual in these cases, though it is less uncommon in older patients.

II.—A child who had been ill for a week with cough, severe pain in the right chest and feverishness. An examination revealed the presence of dulness extending to the angle of the scapula. The breath sounds were scarcely diminished in intensity, and it was thought that the case might be one of pneumonia.

Dr. Syers pointed out that the malady was phthisic, and that this diagnosis was not in the least affected by the fact of the well-marked breath sounds. He stated that in children the physical signs of pleural effusion were very often indeed nearly identical—not quite—with those of consolidated lung. The essential difference does not concern the breath sounds, but the quality of the dulness on percussion. The dulness is more pronounced, higher pitched and more uniform than is the case in pneumatic consolidation.

Dr. Syers remarked that fluid was certainly present, but it was altogether impossible to say whether it was clear or purulent unless the exploring syringe was used.

The use of this instrument proved the presence of clear fluid.

III.—A man, aged 20, who complained of debility and of palpitation. Examination of the heart revealed the presence of a systolic murmur at the apex conducted to the axillary region and faintly audible at the angle of the left scapula. There was no history of rheumatism. The murmur was soft and blowing, and Dr. Syers pointed out that it was affected by the movements of respiration. When the patient held his breath the murmur disappeared.

Dr. Syers laid stress on the importance of not mistaking the real nature of the phenomenon. He asserted that the murmur was certainly not indicative of organic heart disease, but was due to the pressure of the ventricle upon the left lung. The murmur
was audible during inspiration when the heart and lung came in contact. These murmurs were very frequently met with by those whose duty it was to examine large numbers of recruits, and unless they were thoroughly understood, cases really suitable for the Services might be unnecessarily rejected.

BRITISH SANATORIA FOR CONSUMPTION.—XIII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE NATIONAL HOSPITAL FOR CONSUMPTION FOR IRELAND.

While pulmonary tuberculosis is steadily declining in England, statistical returns seem to indicate that in Ireland no diminution is occurring, and that in some districts it is even increasing. Certainly phthisis is extremely prevalent in the Emerald Isle. This is apparently due, in great measure, at least, to the widespread destitution, the wretched habitations of the poor, the insufficiency of suitable food, the widespread addiction to excessive alcoholic indulgence, and the prevalent ignorance respecting the hygienic requirements.

The means at present available for dealing with consumption in Ireland must be considered altogether inadequate. There are two public institutions—the National Hospital for Consumption, situated near Newcastle, in County Wicklow, and drawing cases mainly from Dublin and district; and the Forster Green Hospital at Fortbreda, Belfast, providing chiefly for patients in the north of Ireland. At the present time there are only two private sanatoria in the whole of the country—Altadore Sanatorium, near Greystones, in County Wicklow, and Rostrevor Sanatorium in County Down. The National Hospital for Consumption opened early in 1898, with the treatment of poor patients suffering from pulmonary tuberculosis in its incipient and early stages. Patients of both sexes are admitted from all parts of Ireland without any religious or other distinction.

Treatment is conducted in accordance with modern methods. The institution is, in fact, a sanatorium in which the principles of the hygienic treatment of consumption are carried out. The President is the Earl Fitzwilliam, the Vice-Presidents being the Marquis of Zetland and the Earl of Crewe, and there is an influential board of governors. The medical staff consists of nine well-known consulting physicians. The visiting physicians are Dr. Alfred R. Parsons and Dr. James B. Coleman. Dr. H. B. Steede is the resident medical officer, and on him devolves the greater portion of the responsibility of directing the treatment of the cases. There is a trained nurse as Lady Superintendent and a small staff of nurses.

Admission to the hospital is obtained only by a letter of recommendation from a member of the Association or subscriber entitled to recommend patients. The central offices are at 5, Leinster Street, Dublin. A minimum charge of seven shillings a week is made for each patient. A few paying patients are admitted at the rate of thirty shillings a week for men, and twenty-five shillings per week for women, and such have separate bedrooms. The hospital, having only a very small endowment, is almost entirely dependent on voluntary contributions.

The hospital, surrounded by twenty-eight acres of ground, is situated about three miles from Newcastle station on the Dublin, Wicklow and Wexford Railway, and can be reached in about an hour from Dublin. Arrangements can be made whereby cars meet any train.

The site cannot be considered ideal, but nevertheless offers many advantages for the purposes of the consumptive subject. The sanatorium is situated on the southern slope of an open grassy upland, and lies about midway between the sea on the east and the Wicklow mountains on the west. The building and grounds are somewhat lacking in shelter, but allow of good exposure to sunlight. The sanatorium is nearly three miles from the sea, and about two miles distant the hills rise to nearly 800 feet. The soil consists mainly of gravel, and is consequently very porous, soon dries, and is convenient for the system of drainage.

The system of sewage disposal has recently been remodelled by the construction of a septic tank and filter beds, and is said to work well. The hospital ranks as a fairly equipped meteorological station of the "second order."

The general character of the building will be ascertained from the following description. The central portion is devoted to administrative purposes. On either side is a three-storied block, one for men and one for women, separated from the central block by a garden. Verandas are provided for the patients while resting. The balconies on the first floor are unfortunately too small to conveniently take a bed. The rooms and wards are good and well equipped for their special purpose.

Several important additions have recently been made, and include a new kitchen, laundry, servants' hall, store-rooms, and rooms for nurses and servants, and also a disinfecting chamber.

On the men's side there is a comparatively new pavilion, which contains four large airy wards, two smaller ones, and four staff rooms, besides the necessary baths and lavatories, and accommodates twenty-six male patients. In front there is a large veranda.

Originally the hospital was ventilated on the plenum system, but now, of course, open-air methods prevail. The windows are arranged so that they can remain open constantly, but arrangements have been made whereby the wards can be warmed by steam.

It is hoped that a new pavilion may soon be erected on the female side of the sanatorium, for at present a large number of applicants are always awaiting admission.

Treatment is conducted in accordance with the principles of a strict hygienic existence. Open-air life is insisted on, exercise and rest is carefully regulated, the food is good and abundant, and every patient is subject to more or less constant medical supervision.

Dr. Steede lives in the grounds in a house specially built for the residence of the medical officers.

According to the medical report for last year, 29 patients were under treatment. Improvement was noted in 32 per cent. of the cases; only six died. Gain in weight was recorded in 90 per cent. of the patients, and weight increase was over a stone. As is too frequently the case, patients do not usually apply for admission until the early stage has been passed. The medical report merits much praise; is a most carefully compiled document, and manifests a fine scientific spirit. We are glad to find that in recording the results of treatment the temptation to classify cases as "cured" has been resisted, although abundant evidence is afforded to warrant the conclusion that in a considerable number of instances the disease has been arrested. The report contains particulars concerning the daily routine, and in an ingeniously arranged table the patients are classified and results of treatment concisely expressed. Abstracts of the clinical records of a large number of cases are given and afford interesting evidence of the care with which individual cases are studied.

Efforts are made to instruct patients in the rational conduct of a hygienic life, and it is believed that many on leaving the sanatorium still maintain open-air habits. Deltweller's expectoration plates have been in use constantly since the hospital was opened in 1898. Strict precautions are taken to ensure thorough dissection of all sputum; it is collected twice daily and completely burnt in the engine furnace.

The central offices of the hospital are at 5, Leinster Street, Dublin, and there is no city out-patient department in connection with the institution, where new cases can be examined, and where also waiting and former patients could perio-

ANKYLOSTOMIASIS.

A great deal of attention is being paid to the existence among the miners of Europe of a kind of worm, located generally in the duodenum and the small intestine, producing gastric disorder and, as claimed by some, miners' anaemia. The name given to this helmint is ankylostome.

Its nature was described by Professor Perroncito, of Italy, who found it in the dejections of the workmen cutting the tunnel of St. Gothard, and who suffered from anaemia with considerable disorders in the intestine. The Swiss doctors on the other side were charged by the Federal Government to verify the assertions of the Italian professor, and found them correct. Subsequently attention was turned to the miners, whose work is somewhat similar in its conditions to that of piercing long tunnels, and in these the parasites were found in abundance, especially among the Austrian and German miners. The French doctors immediately made similar researches in the mines of their country and discovered the same ankylostome.

But here a difficulty arose. Whereas the Italian confreres pretended that the miners' anaemia was due to the presence of these parasites, which in certain individuals attained fabulous numbers—one to two thousand—the French school refused to admit the assertion, declaring that the anaemia was solely due to insufficient aeration, and that in many such cases the worms were absent.

However that may be, it is conceded by all that ankylostomiasis, or the presence of ankylostomes in the intestine, is an affection which materially injures the health of the miner and is easily propagated by the men, who ease themselves promiscuously in the galleries. The recent Medical Congress held at Brussels treated the subject at great length, and finally came to the conclusion that water-closets should be prepared for the men at the surface of the mine, where they should be invited to go before entering the mine, and that receptacles should be placed throughout the galleries for urgent cases. The men should be also instructed on the dangers resulting from infection by the parasite. The French Government has already responded by inviting all the mine doctors of the Republic to send in reports on the presence of ankylostomes among the miners under their care, and to indicate what measures have been taken or should be taken to stamp out the disease.

by PATIENT LOST THROUGH THE TELEPHONE.

A woman patient at Bordeaux was in communication with a patient. Husband: "The condition of my wife is worse, the treatment was not energetic enough." Professor: "We will try the new treatment which I mentioned to you." Husband: "What is it?"

At this point the communication was switched off at the head office, and the husband heard: "I think she is covered with excoriations inside. Let her cool all night, and before heating her, take a hammer and strike her on all sides vigorously!" Evidently it was an answer to some fireman about a steam boiler, but the professor never saw the patient again.

NUMBER OF DOCTORS IN FRANCE.

A census has just been published of the number of doctors in France. It amounts to 18,735, or 1,751 more than the previous year.

Germany.

FROM OUR OWN CORRESPONDENT.

[Berlin, September 29th, 1903.]

The last number of the Therap. Monatschrift has an article by W. Friedländer on Syphilis and locomotor Ataxy, written with a view of determining the etiological connection between the two. Instead of the question, "How many tabetic have had syphilis?" he would ask, "How many syphilitics get locomotor ataxy?"

Reumont, among 3,600 people who had had syphilis, found only forty cases of locomotor ataxy. Nefelt observed that in Central Asia, where he practised for six months and where syphilis was rampant, he did not see a single case of locomotor ataxy. Holzinger, in Abyssinia, where there was an extraordinary spread of syphilis, found locomotor ataxy only very rarely. Däubler, among the negroes on the Zambezi, found syphilis very prevalent, but saw no case of locomotor ataxy. In Abyssinia from 80 to 90 per cent. of the population was syphilitic, and in Zanzibar about five-sixths of the population. In Siam at least 30 to 80 per cent. of the European population had had syphilis. In spite of this general spread of syphilis, the so-called metastatic forms of the disease, tabes and progressive paralysis, were either very rare or altogether unknown. From all this Friedländer concluded that syphilis cannot be the sole cause, or even the most frequent cause, of the disease, as many authors have assumed. V. Düiring, of Constantinople, whose experiences had been very extensive, came to the certain conclusion that syphilis per se could not be the cause of tabes and paralysis. Among the ten thousands of locomotor ataxies in Asia Minor scarcely a tabetic or a paralytic was to be found. The statistics of Fournier were opposed to this. Among 1,000 cases of locomotor ataxy he found 929 who had had syphilis. This author, who looked upon syphilis as the most important factor in the disease, confided the importance of neuropathic weakness and of nervous irritation or over-stimulation, and that tabes was always refractory to antisyphilitic treatment.

Edinger had succeeded in producing changes in the posterior columns and posterior roots in rats that had been made to work very hard. This degeneration, analogous to that of tabes, was caused more readily in rats that had been previously rendered anemic (by prazide). On the basis of these experiments, he had propounded the hypothesis that locomotor ataxy developed in individuals whose organisms had suffered much and become weakened from various causes, among which syphilis might be one; to this must be added the second factor, excessive strain and fatigue of the nervous system. In pure uncomplicated tabes antisyphilitic treatment was risky. A necessary result of the acceptance...
of Edinger's theory will be the maintenance of perfect bodily rest along with good feeding. Suitable hydro-
therapeutic measures would also be useful. As to the employment of "compulsory exercises," opinions are
divided.

In the D. med. Zeitung (7/4/1903), Dr. Bialyolyzski
has a reference to the use of

**METHYLENE BLUE IN URINARY DISEASES.**

In the Child Jesus Hospital in Warsaw, he has used it
in both acute and chronic affections of the urinary
passages, with the best and quickest results. It acted
less rapidly, but always favourably, in supplicative
affections of accidental origin. In gonorrhreal affec-
tions, also, improvement took place; in tuberculoses
diseases the pain and burning passed away, and also
the frequent desire to micturate, but the treatment had
no influence on the tuberculous process itself. In
cases of bladder insufficiency, also, improvement was
obtained. Summing up, he concludes that methylene
blue possesses a calmsative, antiphlogistic and anti-
fermentative action, and that, moreover, it strengthens
the bladder and regulates its function. He has noticed
that in some cases it has caused nausea at first, but in
the end patients have all borne it well.

It has been given in the same doses of 0.0 and
untrollable diarrhoea of phthisis in doses of 0.15 grms. per day.
The following recipes have been recommended:

1. **Methylene blue, 0.15 grm.**
   
   Lactose, 0.0 to 0.8 grs.

2. **Methylene blue, 0.05**
   
   Lactose, 0.2 grs.

Three or four to be given in the day.

The lactose is for the purpose of dividing the powder
better and enabling it to be better borne. The liquid
motions cease very quickly, and may even give place
to constipation.

At the Surgical Society, Hr. F. Krause read a paper
on The Surgical Treatment of Non-Traumatic
Jacksonian Epilepsy.

He said that according to recent investigations, only
the anterior cerebral convolutions were faradically
excitable. This had been tested in the human subject,
and had been found to be the case here also. The
speaker had treated invertebrate cases of Jacksonian
epilepsy starting in a certain group of muscles by
opening the brain, and after determining by faradisa-
tion the point in the cerebral convolutions from which
the epilepsy proceeded, had extirpated it. The first
case was that of a boy, aged 9, who at six years of age
developed Jacksonian epilepsy after an attack of
encephalitis, and who remained imbecile. He made an
extensive trepanation over the anterior cerebral con-
volution, and found a large subconrual cyst below the
region of the facial nerve. After extirpation of the
cyst the epilepsy ceased, and the mental development
became normal. One would, however, have to wait
several years before being quite sure of complete recov-
ery. (2) A case in which the brain surface appeared
to be normal; he ascertained by faradic stimulation the
diseased spot on the lower border of the anterior con-
volution, and excised it to a depth of 5 mm. with a
successful result. (3) A man, aged 36, who up to sixteen
years of age had been healthy; then he had hemi-
plegia with Jacksonian epilepsy, which, in spite of all
treatment, continued unchanged for twenty years.

Here was a slight leptomenigitic change shown by
stimulation of the posterior cerebral convolutions,
extirpation, and recovery. (4) A young seaman;
epilepsy after ascertainment. The spot by faradic
stimulation. Recovery. But how should one proceed
when no anatomical change could be found? The

**VIENNA, September 26th, 1903.**

**EARLY DIAGNOSIS OF TYPHOID.**

Adler recorded his experiments in the diagnosis
of typhoid, and confirmed the agglutination test as
fair a one as we yet had at command. His method of
applying the test is to puncture the spleen with the
needle of a fine syringe and extract one to ten drops of
the fluid with antiseptic care, and then put in sterile
boil bouillon or the serum of a goat diluted to 1 in 100,000.

These experiments have been positive in 94 per cent.
of the cases. The puncturing of the spleen is
an innocent operation except in those suffering from
hemophilia, hemorrhagic diathesis, arterio-sclerosis,
or old age.

**PATHOLOGICAL URINE.**

Jaksch contributed a paper on the distribution of
nitrogen eliminated during the different diseases,
and affirmed that urea was not an absolute measure of
the amount of the nitrogen eliminated, although
urea expresses the largest quantity of it. Yet there are
other bodies not precipitated by tungstate of phos-
phorus and containing a large amount of the nitrogen,
which may be considered amidogenic bodies. These
appear in the urine of patients suffering from nephritic
disease, phosphorus poisoning, diabetes insipidus, in a
less degree in diabetes mellitus, and in typhoid.

These bodies are usually increased in their nitro-
genous property 20 to 25 per cent. in the form of
amidogen or allantoin.

**DIFFERENTIAL TEST IN PHTHISIS.**

Petruschky has published a test to define the pre-
sence of tubercle that may be as reliable as the test
of tuberculin itself, to which he compares it. He tells
us there is pain or tenderness to impressions over the
spinous processes of the third, fourth, fifth, sixth and
seventh dorsal vertebra, which he now recognises as incipient phthisis. In all such cases he has applied the tuberculin injections and found the reaction positive, and looks upon the symptoms as pathognomonic probably due to the initial changes in the bronchial glands, which may give rise to a sort of latent spinalgia. Out of 285 school children he has found it present in thirty-seven, or 13 per cent.

Fürst remarked that in young children we had as yet a very imperfect knowledge how the mesenteric glands took on the tuberculous condition, but we had less about the introduction of the bacillus into the bronchial glands.

Kraemer thought the spinalgia described by Petruschky was more likely to be pathognomonic of spondylitis than tuberculosis of the lung. It is an acknowledged fact that the lung is first affected by the inhaled bacilli before the bronchial glands are affected, and therefore not an early symptom of tuberculosis at all.

Zupnik disagreed with the last speaker, and thought the bronchial glands were early affected.

Singer said he had seen the disease commence mysteriously in the saphenous veins, where no history was to be traced to his ancestors. He then detailed the history of a young man, healthy and strong, with an excellent history, who one day took on inflammatory symptoms over the course of the saphenous, in which tubercle finally was proved.

Mitulescu thought the stage of this disease was an important point in the discussion. He was inclined to divide the changes of the life history into three periods: (a) Evolution, or the initiatory period of development; (b) the period of rest; and (c) a period of devolution or organic degeneration. In the first case the bacillus multiplies and the organism is benefited. During these changes no bacilli are to be found, and the only diagnosis to be relied upon is the tuberculin injection. After an indefinite period of quiet the third stage of degeneration appears when the bacilli are thrown off and the diagnosis confirmed. The lesion at this period is too great to be remedially improved.

Hungary.

[From our own correspondent.]

— Budapest, September 29th, 1903.

At the last meeting of the Nagyvárad Medical Society, Dr. Fräter Imre exhibited a patient with a femoral hernia, incarcerated for fourteen days. The patient, an elderly woman, became very exhausted, the pulse could scarcely be felt, and the limbs were already cold. Operation had to be performed forthwith, to save life. The patient was only anaesthetised by Schleich's method. The incarcerated gut portion was already gangrenous, and during the operation it fell back into the abdominal cavity, so that some of its contents escaped into the abdomen. The diseased gut portion was dissected out, and the ends were united with a Murphy's button; the peritoneal cavity was irrigated with hydrogen dioxide. The edges of the peritoneum were not sutured, but left as they were, and Mikulicz' tamponade was applied; that is to say, the whole cavity was packed with iodiform gauze.

In the course of three or four days the pulse became stronger, the temperature fell, and the patient made an uninterrupted recovery in twenty-one days.

Fräter Imre has employed the Murphy's button already in upwards of one hundred cases, and never has the patient to regret having done so, despite what other surgeons say, cit., that the button cannot escape through the ileo-caval valve.

Dr. Révész Vilmos gave a lecture on Pneumonia Fibrinosa Chronica.

He observed, in his clinic, many cases of this sort, and already possesses the correctness of diagnosis. In the autopsy in the fatal cases. Compared with the great number of the acute pneumonias, it may be said that the chronic cases are of uncommon occurrence. The investigators are unable as yet to settle the question, whether the chronic fibrinous pneumonias stand in any pathalogical relationship with the acute pneumonias or not. Most authors assert that such is the case, in which the disease is attacked by a different form. Whether evolved from a genuine pneumonia, when it is genetically dependent on it, or whether it be an independent pathalogical form, we must consider this variety of chronic pneumonias to be primary because they were not preceded by other changes of the lung tissue.

As to the diagnosis, it is much easier in the later stages than at the onset of the illness, when it is very similar to acute pneumonia. Whether it be associated with tuberculosis can be decided by the examination of the sputum. Diseases of the heart valves are also easily diagnosed. The prognosis as to perfect recovery is not favourable, but life is not endangered even if one lung is shrunken.

Regarding treatment, after the cessation of the acute stage treatment should consist of improvement of the hygienic conditions. The lecturer has chosen the combination of methods advocated by Marchand and Kalden; by this method the mechanical obstacle to the influx of air is put aside. Nominally the authors in question held that owing to congestion in the lungs, alteration in the tone of the mucous membrane cannot be absorbed as brought up. Therefore the lecturer has artificially improved the mobility of the lung by means of massage. Several times daily the chest is rubbed with a 6 per cent. solution of iodosogen, whereby great pressure was exerted upon the smeared surface. At the outset of this procedure the rise of temperature made its appearance, but this promptly subsided after administration of quinine.

Dr. Schiff Ernö, Director of the Hospital for Sick Children, read a paper on Cerebral Abscess after Typhoid.

T. P., aged 92, the late offspring of a musician, fell ill with headache and fever on December 4th. The fever gradually rose in the first days, when, on the sixth day, enlargement of the spleen, roseola, and other signs of typhoid fever made their appearance. In the urine well-marked diuresia was observed. In spite of the fact that the fever reached 40°2⁰ C., not the least alteration was shown in the sensorium of the child. Nay, in the second week of the disease he was mostly sitting in his bed, playing with his toys; and ultimately all the characteristic symptoms of typhoid disappeared, and coincidently with this the morning temperature sank below normal, while even in the afternoon a subfebrile condition was the rule.

Although the typhoid had been recovered from, and the child felt quite well, yet the evening temperature remained subfebrile. Searching for the cause of this state, he failed to elicit any obvious lesion, till the following observations were made:—(1) The pulse-rate became gradually (beginning on January 10th very
high. (2) The increase of the rate of respiration (25-35),
the lungs being not the least diseased. (3) Re-
petual rigors. On April 4th the third stage of
the disease commenced. There was severe headache, and
in association with this vomiting occurred, and soon,
also, photophobia was noticed. The pupils were
dilated, and reacted sluggishly, perception dim, pulse
irregular. On April 21st twitchings were seen in other
muscles, and total aphasia supervened. On April 24th
moderate trismus, aphasia, disartria, and ptosis of the
lids were noticed. From this time the boy became
gradually emaciated. The pulse-rate had been 130-170.
Finally death ensued on April 30th.

The whole pathological picture was in favour of the
diagnosis of a cerebral abscess. As to localisation,
the symptoms of the disease pointed to an abscess
seated in the left lower part of the frontal lobe.

The Medical Section of the Hungarian Natural
Scientists held its great touring session in Volosvar,
on September 9th, Count Esterhazy, president of the
Transsylvania Museum Society, in the chair. Among
the papers read great attention was paid to that of
Dr. Donath, who discussed the diagnostic and therapeu-
tical value of the Quincke lumbar puncture. He especially
called the attention of general practitioners to it
as being very simple, effective, and free from danger.
He had performed it in ninety-eight instances, and
never had any inconveniences with it. Especially
was it found valuable in cases of in-flammation of the
meninges, having a very effective, soothing action;
further, in the gastric crises of tabetics and in the
status epileptics of epileptics. (Donath was the dis-
coverer of the fact that the cramps of the latter are due
to a poisonous metabolic product—viz., cholin.)

Great attention was paid also to the address of
Professor Hephim Apáthy, who read a paper with the
title, 'The World of the Microscope.' 'For sake of brevity
we need only mention the prominent feature of
the dissertation. The author said that the per-
fec tness of microscopical technique had arrived
to-day at such a degree that we could not be satisfied
with the micro-millimetre, that is "µ," but we shall
shortly be compelled to introduce also a smaller unit,
for which purpose the best would seem the acceptance
of the thousandth part of the mikron, to which Dr.
Apáthy would like to give the name of "millimikron."

The Operating Theatres.

ST. JOHN'S HOSPITAL, TWICKENHAM.

NEPHROGRAPHY.—Mr. CARLESS operated on a woman
aged about 40, who had suffered from movable kidney
for many years. She was a thin, spare subject, and
both kidneys could easily be felt moving up and down
on respiration. The excursions were very considerable,
and the patient complained of pain of a renal type and
suffered from nausea and occasional vomiting. As the
left kidney was the more painful, it was decided to deal
with this first. The usual oblique incision was
made across the loin, dividing the muscles. The last
dorsal nerve was seen and pulled on one side. The
loose perinephritic fat thereby exposed was opened
freely, and the kidney freed from it over the whole of
its posterior surface. A considerable amount of this
loose fatty envelope was pulled away. The kidney
was then handled by the hand of an assistant, and a
rectangular flap of the true fibrous capsule dissected
off the cortex backwards; this flap measured three or
four centimetres in length, and two centimetres in
breadth; it was left attached towards the hilum, and a
pair of Spencer Wells' forceps was temporarily placed
on its apex. Silk stiches were then inserted by means
of a hernia needle through the muscular margins of
the wound at the top and bottom, passing en route
through the kidney substance above and below the
detached flap of the capsule. These were tightened
after the kidney had been pushed back into position
against the abdominal wall by the hand of an assistant
placed on the front of the abdomen. As these stitches
included a portion of the capsule and a firm hold of the
kidney was thereby secured, and the up and down
movements of the organ during respiration at once
ceased. All bleeding points were now secured, the
wound in the muscles was closed by a sufficiency of
silk sutures, some of which passed through the flap of
the capsule, which was brought out through the incision,
the apex being finally stitched down by a buried catgut
suture to the outer aspect of the muscles. The skin
was then closed by a continuous suture. No drainage
was required. Mr. Carless has tried most of the many
methods of fixing kidneys. He was one of the first, if
not the first, to attempt Bulbet's operation in this
country (a case of this type was reported in "Operating
Theatres," November 25th, 1896). He had come to
the conclusion, however, that it appeared to him to be
better than any of the other plans which had been
suggested apart from decorticitation of the organ. He
thought it was hardly reasonable to suppose that a
smooth structure such as the kidney in its capsule
would become adherent to the abdominal parietes,
especially when one knew how readily sutures are
absorbed when passed through the kidney substance.

Other surgeons removed nearly the whole of the capsule
from the posterior aspect of the organ by a crucial
incision and fixed the tags of capsule thus formed to
the muscles; personally, Mr. Carless considered the
plan he had just adopted preferable; a sufficient area
of the cortex was uncovered to secure firm adhesions,
and the stitches passed through the organ above and
below the bare area sufficed to hold it in place. These
adhesions were forming, even if they did nothing
more. Unless some portions of the capsule were left
no deep stitch through the gland could be expected to
hold. It was also an important detail to press the
kidney back into position from the front before tightening
these deep stitches.

A Sanitary Crusade Round the World.

Mr. RONALD BOYLE, the well-known sanitary engineer,
is a practical as well as a scientific exponent of the laws
of health, and among the many benefits he has con-
served upon humanity as a pioneer in sanitary reform
may be mentioned the gift of £10,000,000 by him last
year on the occasion of his Majesty's Coronation,
for the purpose of promoting the teaching of hygiene
in the schools and colleges of the Empire. He has
recently returned from what constitutes his eighth
sanitary crusade round the world, having encircled
the globe that number of times preaching the gospel
of pure air and advocating the adoption of hygienic
measures that would tend to secure the better health
and consequent welfare of the peoples of the many
countries he has "rung from China to Peru." Mr.
Boyle having on one of his crusades travelled through
China to its most remote boundaries, and last year the
West Indies and South America.

Typhoid Fever at Merthyr.

According to the report of Dr. D. J. Thomas, the
medical officer of health for the Merthyr Urban District
Council, the outbreak of typhoid fever in August last
was due to the contaminated fish. The kidney
through we cannot say that this assertion is satisfac-
torily established in the report in question. The
alllegation is based on the assumption that the shell
fish became contaminated after their arrival at Merthyr,
which, on the face of it, is unlikely. Still, the evidence
of the epidemic having had its source in the cockles is
very strong, and the only doubtful point is how they
became the vehicle of the poison.
AN IMPERIAL MEDICAL SOCIETY.

There are times for thought and times for action, and a subject we would submit at this holiday period for the reflection of the profession is whether the medical societies of the Metropolis are fulfilling their functions to the best advantage, and, further, whether those functions could not be enlarged and adapted to wider ends. There are some seventy societies, each appealing to some section of the profession, either by their aims or by their locale. Some of them are identical in aim, such as the Medico-Chirurgical and the Medical; others overlap, such as the Medico-Psychological and the Neurological; all tend to the formation of cliques. Every man is confronted with the problem—which societies shall he join, and how many societies can he afford? Not infrequently he relieves his perplexity by joining none. This course does not tend either to the diffusion of knowledge or to good-fellowship. Again, of what do the usual society's proceedings consist? A paper by one man, generally the record of some half-dozen successful cases that have been under his care, followed by a desultory discussion, taken part in by a few members, who think they would have been no less successful had the cases been in their own hands. Dr. A. thinks that peptonuria occurs more frequently in empyema than appendicitis, whilst Dr. B. inclines to the opposite view; C. feels that A.'s and B.'s reagents must have been at fault, for whereas peptonuria is rare in either condition, albuminuria can almost invariably be detected in both. However, A.'s paper passes into the society's transactions—a fact recorded against A.'s name in the "Medical Directory"—and no one is much the better, or worse. A man who belongs to three or four societies finds at the end of a decade or two that his book-shelves are encumbered with a mass of literature in the shape of these transactions, whose interest is quite ephemeral, and he is constrained to take counsel with the second-hand bookseller, who buys by the pound, or to find ignoble uses for the volumes. There must be some radical defect in our system if the energy and money expended on society work—we speak of serious societies, not such as aim at providing relaxation in the shape of social gatherings—conduce to no more permanent, far-reaching, and useful results than these. Two objects we should like to see aimed at especially, amalgamation and concentration; amalgamation into one large society or academy with organised subsections, and concentration of the work of the sections on definite objects. By these methods we believe not only would intermingling tend to obviate the dangers of exaggerated specialism, but the work of the specialists might be made available to the general body of the profession. A central body, with a chosen council on which all interests were represented, could control, govern, and manage the collective work of the sections, prevent overlapping, and direct enthusiasm, aptitude, and energy into the most useful channels; whilst general problems in medicine and general subjects of interest could be discussed at general authoritative gatherings. Individualism would be given full play at sectional meetings, where egoism might be carefully repressed; but the common sectional good would be subordinated to the common academical good. Concentration of work on definite objects could be carried out to the greatest advantage. As a model of the work for sections, we would hold up the report of the Committee of the Clinical Society on Myxœdema, published by that Society in 1888. This report has an authoritative and permanent interest. It presents in the compass of one volume all that was known of myxœdema, historically, pathologically and clinically, at the date mentioned, and no one wishing to make himself acquainted with the subject need go further back in his investigations than that year if he wish to read all that was worth knowing in the year '88. If he do, there is a complete bibliography of the subject attached. We venture to think that were the work of the sections of a central society or academy focused in some such manner as was this Committee's a substantial and durable benefit would result, not only to the investigators themselves, not only to the whole society, but even to the whole mass of English-speaking practitioners of the art of medicine. Such work, however, can only come otherwise than spasmodically, by organisation, cohesion, and systematisation, but for all the topics which would engage the attention of the sections of such a society to be dealt with in this fashion would be an unspeakable boon to the general practitioner who wishes to know, not what the opinion of individuals is, but what is generally agreed upon by those who are especially well acquainted with a subject or department. But the advantages that would accrue to the general practitioner would by no means end here. Although unable to attend central meetings he
could, by being a member of the society, obtain his reports of all that went on in every section at a far lower figure than if he belonged to half the societies now extant, and he would have access to an indispensable adjunct to such a society, namely, a well-stocked library. A subscription of two guineas a year would attract a membership of two-thirds of the profession, and even such a society ought to be financially stable with an income of forty thousand pounds. To attain these ends, we repeat, there would have to be a sinking of the individual interest into the communal, and the success of such an undertaking would rest entirely on the self-abnegation of the members. Facilities for self-advertisement would have no place in its design or method. It remains to be seen whether medical men possess this virtue in sufficient degree.

THE CARE OF THE BRAIN.

The ascendency of the genus homo in the scheme of animal life upon the earth is obviously due to his superior development of brain. To the individual the healthiness of that important organ is of supreme importance. While he may on the one hand get through life with average comfort and happiness in spite of some grave bodily defect, yet on the other hand his lot will be sad indeed should he be cursed with a defective brain. There is reason to suppose that such propositions, commonplace as they may appear, are apt to escape due recognition by those responsible for the care of the brain both in its early and in its mature stages. It is a matter of vital importance, for instance, to recognise in infancy the quality of the individual brain action, whether that be defective, normal, or above the average, inasmuch as each condition demands careful and particular treatment. It is lamentable to reflect upon the irreparable injury to the intellectual commonwealth of the nation resulting from the ignorant methods of the nursery. The recognition that the Infant Feeding and Care of Infants Board is a hopeful sign of the times. Mr. Chaplin, although by no means an ideal statesman, nevertheless distinguished his term of office as President of that branch of the executive by the classification and separate housing of defective Poor-law children. Some day it might not be altogether impossible under more perfect systems to separate and foster the brains that are above the average standard, as well as those that fall below that point. Something of the kind has been achieved among the children of the poorer classes by the School Board system, which, in not a few cases has enabled youths of great intellectual calibre to forsake the slums for the class rooms of the University. Nowadays it is the fashion of social reformers to insist upon the necessity of affording "equality of opportunity" to one and all of our citizens, irrespective of accidents of birth and station. The fact that this phrase almost invariably refers to methods of intellectual betterment as the means to the end is not without its significance. It is the glimmering of the dawn. It means that scientific method is being brought to bear upon the problems of the rearing of a mentally sound race. The increase of insanity under the conditions of modern civilised life demands the careful attention of all who are interested in the present and the future welfare of mankind. It seems probable that a vast predisposing cause of insanity may be found in the unwholesome environment of infantile life, such as bad housing, improper feeding, starvation, and neglect. These injurious influences may be found more or less in all ranks of society. Patent foods and want of ventilation may stunt a baby in the nursery of a palace just as much as in a garret in Whitechapel. Public newspaper writers are prone to wax eloquent upon the increase of national insanity. It may perhaps interest them to learn that a certain percentage of the total amount may be reasonably attributed to the patent foods and the patent medicines for children, the advertisement of which brings huge sums to their coffers. As regards adults a considerable amount of insanity is doubtless due to preventible causes. The nutrition of the brain is affected, and at length the organ is permanently damaged by poor living, drink, dissipation, and other exhausting and impoverishing conditions. Nerve poisons, such as tea, coffee, tobacco, alcohol, and various narcotic drugs seems to exercise a peculiar fascination over mankind in all parts of the world. The way in which the brain of the average healthy man can withstand many years of such maltreatment is a marvellous tribute to the perfection attained by the bodily machine as the result of numberless ages of evolution. The stress and worry of competition tell more or less in the long run on the mental powers of many of those engaged in the modern struggle of life. Yet busy men are often the worst offenders in the abuse of their brain. A city man will obey the advice of his physician implicitly as regards his liver, but will follow his own wayward will when his brain, an infinitely more delicate organ, is concerned. Clearly there is room for much education of the popular mind in the search for the ideal mens sana in corpore sano.

THE RESTRICTION OF HOSPITAL PRESCRIPTIONS.

It has long been one of the unwritten rules of medical practice that nothing short of the best, where this can be obtained, is fit to be employed in the sacred art of healing the sick. It is only when that particular remedy or appliance which would be most suitable in a given case cannot, for some reason or other, be procured, that it is justifiable to use inferior means. This is not a matter of sentiment, but one of duty. Just as all that is noblest and most sublime in architecture and music is pressed into the service of the Church, so the highest of human skill, the most recent scientific discoveries, and the costliest remedies which the earth produces or the chemist manufactures are called in requisition for and made subservient to the physical needs of king and peasant alike. Medicine, like religion, is no respecter of persons. The same drug which pro-
NOTES ON CURRENT TOPICS.  THE MEDICAL PRESS.  375

Sept. 30, 1903.

Cures relief from pain for the poor man in his humble dwelling also assuages the distress of the royal sufferer in his palace. There are times, of course, when temporary measures have their proper place, as when a broken limb is bound by sticks and pads by an intelligent "first-aider" preparatory to its final setting in the more elaborate and scientific hospital swing-cradle, or when the village practitioner is compelled, in an emergency, to use the first drug which comes to hand, there being no time in which to obtain the newer and, perhaps, more efficient remedy. Against such we have nothing to say, but when a hospital, which stands before the public as a place above all others where the latest and best of its kind is supposed to be ready at hand for the use of any sick person, is deliberately asked or expected to withhold its best, to shorten its helping arm, and to offer that which is inferior simply upon the grounds of economy, we feel it to be our duty to utter a protest in the name of the sick poor for whom such institutions were founded. It cannot be that the Metropolitan Hospital Sunday Fund will really seriously insist upon reductions being made in the amount spent on drugs, as it appears to be endeavouring to do. While it is quite right, of course, to guard against unnecessary waste or possible extravagance, it is surely needful to ascertain first whether any abuses in this direction actually exist. A little reflection cannot fail to reveal the fact that the most efficacious remedy, whether it is the most expensive or not, is, in the end, the most economical, for the patient is thereby cured the sooner and therefore either ceases to attend the out-patient department or is discharged from the wards. Again, a patient in receipt of out-door relief does not continue to take his medicine for an indefinite period; it is quickly changed by the physician in charge or dropped altogether. In this manner one remedy is provided against hospital abuse. It is, therefore, in the highest interest of any hospital to employ that drug which is known to act best and most quickly, regardless of expense, within certain limits, for by so doing it places itself in a position whereby it is able to benefit a large number of people. It is the general consensus of opinion that in out-patient prescribing, where extravagance might be supposed to prevail most, economy is practised to the greatest extent. It is to be hoped that the Committee of the Hospital Sunday Fund will re-consider their decision before it is too late, so that this body may remain in the future what it has always shown itself to be in the past, namely, one of the best friends of the metropolitan hospitals.

Notes on Current Topics.

Vaccination and National Economy.

Now that the report of the Metropolitan Asylums Board dealing with the small-pox epidemic of 1901-02 has been issued, the opportunity arises for the keen statistician and the political economist to deduce therefrom those moral lessons which such a document cannot fail to inculcate. Though it may be acknowledged that figures may be distorted in order to suit a particular theory, yet there is no denying the fact that statistics speak for themselves, and that with no uncertain voice. An analysis of the report by Dr. E. Garrett Anderson, the Hon. Secretary of the Imperial Vaccination League, in a recent letter to the Times, shows very plainly the value of systematic re-vaccination at school age, and the question is raised as to whether small-pox epidemics could not be entirely prevented by such means. Thus, while not a single death occurred in 1902 among vaccinated children of all ages under seven, the protective power of vaccination in infancy is seen to steadily decrease with each successive year after this age, but in spite of this diminution the influence of primary vaccination is an important factor, as the mortality occurring from 15-30 was only 48 per cent. among the unvaccinated, as compared with 304 per cent. in the unvaccinated. It is, therefore, among the adult population of London that protection against small-pox is insufficient, owing to the fact that we have as yet no system of re-vaccination as a routine measure. The practical outcome of this unsatisfactory state of affairs is that the country is continually expending a large sum of money in methods of isolation, which include the upkeep of the special small-pox hospitals as well as the provision and maintenance of temporary ones, and in panic vaccination in times of an epidemic. There is always some expense going on in connection with the hospitals and ships, with the necessary apparatus for transport of patients, and this is greatly increased in epidemic years. Moreover, the cost of each epidemic is going up. The ratepayers are, therefore, burdened by these additional charges which need not be incurred at all if a system of organised re-vaccination could be adopted. Unless this be done, epidemics of small-pox are bound to recur. When it is realised that in 1902 the Metropolitan Asylums Board raised a sum of very nearly a quarter of a million more than that raised in 1900, and that £24,608 is the amount of the unpaid portion of the debt incurred by that body, and directly attributable to small-pox, it will be seen that a vast sum is needlessly expended which, if it could be diverted into other channels, might be productive of some real benefit to the public. If we could take a lesson from Germany in the matter of re-vaccination we should soon see the gradual disappearance of this dire preventible disease from our midst.

Left-Handedness.

Professor Lombroso is nothing if not ingenious, and his latest expansion of criminological science may cause a mild shock to those of us who have left-handed relations. We have hitherto been accustomed to think of them as the subjects of a minor freak of Nature, and the only people inconvenience by their peculiarity to be the fieldsmen at a cricket match. But we have been too superficial in our view and too indulgent. In future they must be watched, for they are degenerates,
and lurking in them, according to this eminent psychologist, lie the seeds of idocy, lunacy, and crime. They are reversion to the ancestral type, for in twenty-seven anthropomorphous monkeys Professor Lombroso found the left shoulder stronger than the right; and people who "throw back" are not normal. The reason that the right hand is employed more frequently and for more complex movements than its fellow is "that the left lobe of the brain is larger than the right, and therefore the brain from the left is more directly and in greater quantities." Left-handedness is more common in women than men, and this is especially seen in criminals, among whom Professor Lombroso found 13 per cent. of the males studied were left-handed, and 22 per cent. of the females. Woman is admittedly a less highly-developed organism than man. A fresh abnormality is described under the name of "left-sidedness," in which the whole of the left side is more sensitive than the right; but although this is not so damning a fault as left-handedness, we are reminded that "the proportion of sensitive left-sided persons among criminals becomes very much more if one takes into account the sensibility to pain, which they have more highly developed in the left side." For the ambidextrous there is a little comfort; the equal development of his cerebral lobes is likely only to lead to "complete inertia"; "second childishness and mere oblivion" are to be his portion. We trust that some of our leading ophthalmic surgeons may find solace in the prospect that Broadmoor and Bethlehem are not for them; their painfully-acquired ambidexterity will probably only land them in some quiet "home."

No, the greatest danger to society is to be apprehended from the left-handed, so that we must keep careful guard over our Benjamins, lest some Exad arise from among them and smite us unawares.

The Value of Heart Reflex.

The phenomenon described by Dr. Albert Abrams (a), of San Francisco, in 1898, known as the heart reflex, which is a diminution in cardiac dulness after cutaneous irritation of the precordial region attributable to diminution of cardiac volume, has not, up to the present, been found capable of any real application in practical medicine. MM. Pierre Merklen and Jean Heitz, in the course of their researches in connection with this physical sign, have discovered that it is not only of interest to the clinician, but that it may also find a place in the therapeutics of heart disease. The results of radioscopic investigation leave no doubt as to the fact of the actual retraction of the heart following tapotage. The reflex is present in normal subjects, but is especially distinct in neurasthenic individuals. It is equally well marked in conditions of acute cardiac dilatation. Its temporary absence has been noticed in enormous degrees of dilatation and of great oedema; while it is permanently wanting in pericarditis and in profound myocardial degeneration with atheromatous change. In comparing the results obtained by mechanical excitation of the precordial region with those derived from bath treatment, MM. Merklen and Heitz find that the first are very little inferior to the second, and they point out that massage and friction of the precordium are generally regarded as part and parcel of the hydrotherapeutic treatment. By taking advantage, therefore, of the natural reflex, and assisted by the inevitable counter-irritation produced by mechanical stimulation, it may be possible to give a patient suffering from heart disease the benefits of a course of baths without their attendant expense and other disadvantages. It is also even suggested that the repeated radioscopic examination with the X-rays, which are really necessary if it be desired to note accurately the amount of cardiac retraction, may, in themselves, have a beneficial effect upon the course of the malady.

Garden Cities.

The term sounds paradoxical—the scheme, Utopian. The garden city plan has been much discussed since Mr. Ebenezer Howard first presented it to the world. It is one that, if it can be brought to maturity, will solve not only many economic problems, but many that those who have the well-being of the worker at heart have been puzzling over since the time of Charles Kingsley. To have at once rus in urbe and urbs in ruri is a consummation devoutly to be wished, and one that, like most such, seems far from becoming a fait accompli. But we find that not only is the Garden City Company actually in existence, but that it has actually purchased an estate of four thousand acres in Hertfordshire, and is trying to get manufacturers to establish factories on it. The first essential is that this should be done, and then the estate can be laid out and developed for the benefit of the population that will be attracted. By taking people out of the large towns, supplying them with work under salubrious conditions, amusing them with healthy pleasures, and providing them with the amenities of a small well-governed community the Garden City Company will be doing a national work; we shall watch their progress with interest and trust that their scheme may be a financial as well as a social success. For companies cannot go on unless they pay, even when they incidentally benefit mankind.

The Action of Chloride of Sodium on the Renal Epithelium.

Since attention has been called to the untoward effects of the ingestion of chlorides by the subjects of nephritis, some light has been thrown on the grave results which sometimes follow the injection of normal saline solution in patients suffering from interstitial nephritis. Drs. Castaigne and Rathery, of the Paris hospitals, have investigated the action of chlorides from the experimental point of view, and their results are very instructive. They found that rabbits subjected to repeated injections of small quantities of saline
solution do not develop any obvious renal lesions unless continued for too long a time, or the solution be too concentrated, when albuminuria may supervene. The ingestion of large quantities of salt by the mouth also induces albuminuria, and this effect is induced more easily in those whose kidneys are the seat of disease. On the other hand, deprivation of salt is promptly followed by manifest renal lesions, which improve, and, if not too advanced, may be recovered from, when the animals are again placed on a proper allowance of chlorides. Briefly summed up, their conclusions point to the fact that persons with susceptible kidneys, or who are suffering from interstitial nephritis, develop transient albuminuria under the influence of excessive doses of salt, and any pre-existing œdem and albuminuria in such persons are accentuated thereby. In massive doses salt determines uremic coma followed by death. The deleterious action of the salt appears to be purely mechanical, being due to injurious osmotic processes.

The Treatment of Incoercible Vomiting in Pregnancy.

The number of remedies suggested, and sometimes employed, for the relief of the obstinate form of vomiting associated with pregnancy in certain subjects is well-nigh as great as for seasickness, and their success is about the same in both conditions. It has been argued, and the suggestion possesses a certain plausibility, that the sickness is due to a variety of auto-intoxication. The fact that the victims of this distressing complication are often albuminuric lends colour to this view, as does the fact that the vomiting usually attains its maximum at the period of the formation of the placenta. Moreover, the theory of auto-intoxication would explain why sickness is sometimes severe and sometimes absent, even in the same subject, for, if the cause were purely mechanical, it would be constant, which is not the case. Proceeding on this assumption Dr. Behm, a German obstetrician, resorts to irrigation of the large intestine with normal saline solution, having previously cleared the bowel by an ordinary enema. The results, he states, have been quite remarkable, the vomiting ceasing in every instance almost immediately. The saline enema should be repeated several times daily, by the aid of a rectal tube, at a temperature of between 65° and 75° F., employing not less than a quart on each occasion.

Should Consumptives be Informed of their Condition?

It is a principle with some practitioners never to give phthisical patients a candid opinion, contenting themselves with a vague statement as to the lungs being "weak," or with some other euphemism calculated to lull the patient into a false sense of security. This practice, we hold, is founded on mistaken ideas of humanity. Admitting that in exceptional cases the news should be conveyed in a guarded manner, how can we get the victim of incipient pulmonary tuberculosis to adopt the stringent precautions necessitated by the treatment and the prevention of infection unless he, or she, be placed in full possession of the facts of the case? The patient who is told the truth may be temporarily depressed, but he soon reacts and enters enthusiastically into the fight. Phthisical patients are, as a rule, prone to hopefulness, and if the truth be withheld, and the medical adviser it may be discovered later from some other source, with inevitable discredit to the original examiner. For the good of the tuberculous patients, for the protection of their friends, and of the public generally, they should be fully informed of their condition. It only remains to impart the intelligence with tact and sympathy, and to infuse the element of hope which is never altogether absent from the prognosis of such cases.

Who Should Appoint the House Surgeon?

A difference of opinion as to whether the right to appoint the house surgeon rests with the honorary medical staff or with the Board of Management has led to something like a strike at the Dewsbury Infirmary; the medical staff having nominated one candidate the Board appointed another, whereupon the members of the medical staff declared their intention to discontinue the work of the Infirmary in the absence of a formal and satisfactory understanding on this point. This is an old "bone of contention," but we must endorse the action of the staff in view of the fact that they are unquestionably better able to judge of the capabilities and professional attainments of the candidate than a board of laymen, who must of necessity base their preference on other than professional grounds. Moreover, the onus of working with the house surgeon rests with the medical staff, and not with the governors, so that the former may fairly claim the right to elect. Such disputes can only arise when there is some ambiguity in the text of the regulations, and in the interests of charitable institutions such ambiguity should be removed and a source of possible irritation done away with. The matter is shortly to be discussed at a special meeting of the Board and the medical staff, when, no doubt, a modus vivendi will be arrived at.

The "Abdominal Parotid Gland."

While the functions of the pancreas in connection with the digestive processes have been ascertained more accurately in recent years, there still remain many facts concerning its pathology which seem to defy explanation. Its protness to inflammation or congestion in the course of many acute infectious diseases is one of these. A case of acute pancreatitis occurring with mumps was described by Dr. Jacob (a) in 1900, and M. Simonin now records the fact that out of 652 cases of parotitis treated in the hospital for infectious diseases at Val-de-Grâce, some affection of the pancreas was found in ten instances. The chief symptom in these was a dull, epigastric

(c) British Medical Journal, June 22nd, 1903.
pain, sudden in onset, relieved by pressure, and often accompanied by nausea and vomiting. The pertinacity of the pain was remarkable, as opium, cocaine, and ice, employed both externally and internally, only afforded slight relief. Its average duration was from two to five days. No albuminuria or glycosuria was observed. The condition was therefore practically one of an acute pancreatitis. M. Simonin believes that these cases tend to support the theory which has been formulated that the abdominal symptoms are due to the interstitial, oedematous infiltration of the gland analogous to that seen in the parotid with compression of the solar plexus or seminal ganglia behind the organ. The pancreas would, therefore, well merit the name given to it by the German school of the "abdominal parotid gland." One interesting point is that the digestive functions of the gland are apparently unaffected by the parotid storm.

Excessive Drinking and Intoxication.

One of the great social problems before the community is the prevention of excessive drinking. It is comparatively easy to place difficulties in the way of people getting drunk, at any rate, when it degenerates into a habit, or, failing prevention, they can be made examples of, pending their incarceration in the drinkless Eden represented by the modern retreat for inebriates. No legislation, however, can touch the confirmed toper who is too experienced and too hardened ever to lose or confuse his ego, still less to commit overt acts upon which an unfavourable construction could be placed by a hard-hearted policeman. Yet the confirmed toper is a far more active and potent enemy of the common weal than his misguided fellow-sinner, since he suffers from the disease of inebriety in a chronic form, and the consequences, if less acute, are none the less disastrous. The deteriorating effects of habitual excessive indulgence in alcohol are well known to psychologists, and need not be emphasised; and there remains the waste of money to the detriment of the family and the waste of valuable time. Improvement can only be effected by moral means, by seeking to elevate the victims, or if this, as is so often the case, be impossible, by prophylactic measures destined to place the rising generation on their guard against this insidious habit which is based on regrettable social habits by no means limited to the working classes and but too much in evidence in classes of society whose education, it might have been hoped, would have enabled them to withstand them.

Professor von Behring on the Prevention of Tuberculosis.

At the Medical Congress, held last week at Cassel, Professor von Behring read a paper on the etiology of tuberculosis and its prevention. Incidentally, he expressed the view that human and bovine tuberculosis are one and the same disease, and that the latter can be communicated to human beings through the agency of infected food, notably by tuberculous milk. He pointed out that the alimentary mucosa of infants affords far more ready passage to the infective agent than that of adults; in fact, it actually traverses the mucosa and enters the circulation. He insisted on the difference between tuberculosis and what is popularly known as consumption. It is possible for a person to have tuberculous lesions without obvious impairment of health, the constitutional symptoms only becoming manifest when, under unfavourable conditions of life, the infection becomes more or less generalised. Of course, there is nothing new or startling in these views, but the Professor hinted at the possibility of his introducing in the near future a means of rendering children immune against infection. He considers, moreover, that the milk of cows which have been rendered immune contains prophylactic elements which may prove of service in the treatment of human beings.

The Latest Electric Fraud.

Our contemporary, Truth, the Editor of which has constituted himself the defender of the public health, inter alia, in respect of electric and medicinal frauds, deals in a very drastic manner with the latest electric humbug whose rhodochodral claims recently found hospitality in the advertising columns of the Times. There is nothing particularly novel in the McLaughlin Co.'s programme. It comprises all the usual tricks to gull the victims of nervous exhaustion or whatever other malady, real or imaginary, may be complained of. Nor is exorbitancy of price, & la Harness, anything but a prominent feature of the business. One would have thought that the curing powers of quack electrical appliances would by this time have fallen into discredit with the public after so many exposures, but no, hope springs eternal in the human breast, and there are always a certain number of willing victims at the disposal of any plausible-tongued quack who comes along. The most regrettable feature is that respectable journals lend their aid to the dissemination of pretences which they must well know to be false in their inception and deceitful in their enunciation. Sooner or later Nemesis will overtake this company just as in the case of its predecessors.

A Digital Manifestation of Rachitis.

No attention is called in current text-books, so far as we are aware, to the influence of rachitis on the shape of the phalangeal bones, possibly because the general indications are usually so pronounced as to render minute observation unnecessary. On examining the phalanges of a rickety infant it will be seen that while the epiphyses remain approximately normal in size the diaphyses tend to undergo enlargement, giving a characteristic outline to the hand, best seen when looked at in profile. The enlargement of the bones bears more especially on the dorsal aspect. Sometimes the finger becomes more or less conical in shape with the apex at the terminal phalanx. These changes are stated to be peculiar to rickets and may be observed during the first twelve months.
of life. When they occur at a later date they indicate a grave form of the disease, being invariably associated with considerable enlargement of the epiphyses and the ends of the ribs. The deformity requires to be distinguished from phalangitis of syphilitic origin. In the latter the deformity affects the terminal phalanx, whereas in rickets all the phalangeal bones are equally involved. The phalangeal manifestations follow the course of the osseous changes elsewhere and subside under appropriate treatment, but the symptom makes its appearance early in the course of the disease and may conceivably prove of service in arriving at a diagnosis.

Insanity in Ireland.

The report of the inspectors of lunatics in Ireland for the year 1903 is the saddest reading. The record, year after year, of an increase in the proportion of the insane to the population, without any abatement in the increase, gives rise to the most gloomy thoughts. To what is this increase due? It commenced soon after Father Matthew commenced his temperance crusade, and has continued ever since. Yet if anything should have arrested the growth of lunacy it was the conversion of the nation from drunkenness to sobriety. In 1851 the total number of lunatics in Ireland was 9,080; emigration, then, and for some ten or more years after, was at its height—tens of thousands of young adults of both sexes left the country; and those that left bred healthy families, even in the crowded cities of the Atlantic seaboard of the New England States. But those that remained bred families who increased the ratio of lunacy, until in 1901 the actual number of lunatics was 25,000. The ratio was one in every 1,336 of the population in 1851, and it had risen to 1 in every 860 in 1901. The exodus of emigrants took away a very large number of the more healthy and vigorous of the people, but it also took away the majority of the me'er-do-wells and relieved the congestion; yet the ratio steadily rose. From the famine years onwards a great change took place in the social condition of the people. Before the potato disease appeared early marriages were the rule; potatoes and butter milk formed the staple food, and in the country the wages were, in proportion to the cost of living, greater than to-day. After the famine all was changed; the diet gradually fell off from nutritious porridge and milk to tea, white bread and American bacon; marriage was postponed to later in life, and with the repeal of the Corn Laws commenced the unrest that has marked the relations between landlord and tenant for more than fifty years. The division between the landlord and his tenant was too often one of race, religion and nationality: Teuton and Celt. The younger members, impetuous from race and age, sought to remedy existing conditions by conspiracy and rebellion, and their futile efforts widened the breach. To make matters worse the value of land for tillage fell daily. The States, Canada, Argentina and Russia competed with Ireland for England's custom. More land laws, more conspiracy, a further exodus, and still later marriages were factors in producing the alarming increase in the ratio of lunacy. Let us hope that in land laws we have reached finality, and that in peaceful occupation and in rest from professional agitation the tenants may acquire wealth and enjoy prosperity, and regain that mental stability that is the only prophylactic against insanity.

From the Particular to the Universal—A New Law in Obstetrics.

Some data by which the size of the foetus in utero can be correctly estimated at full term have been long looked for, and many surmises and observations have been made from time to time as to the nature of the factors that govern foetal development. A contemporary—the Lancet—in its last issue publishes a paper by Captain Lane, J.M.S., in which that writer claims to be in a position to lay down a new law in accordance with which the size of the foetus at birth is determined. "The child grows in utero in such a manner and at such a rate that at full term his size is proportionate to that of the mother's pelvis through which he has to pass in order to be born." This amazing information has been acquired by Captain Lane from the result of the examination of fifty patients at the Eden Hospital, Calcutta. There is only one point that interferes with its importance, and that is that it is not applicable to great degrees of contraction, for, reasoning this time from six cases, we learn that two children born through a conjugate of 3 1/2 inches averaged a greater weight than four children born through a conjugate of 3 7/25 inches. This is very wrong on their part, but perhaps in his next series of half a dozen cases Captain Lane will be able to get more suitable results. A deduction that to our mind necessarily follows from Captain Lane's discovery has apparently escaped his notice—namely, that as the average weight of the foetus is known to increase with the number of pregnancies, so the length of the conjugate diameter must also increase pari passu. Captain Lane has also discovered that vesico-uterine fistulae are very rare, seeing that in eighteen months' practice at the Eden Hospital he did not see a single case, whereas vesico-vaginal fistulae "were not infrequently seen." Captain Lane deduces from this that the uterus is, in the great majority of cases, drawn up out of the pelvis during labour. We would suggest that if the hospital authorities took the same care to prevent the occurrence of vesico-vaginal fistulae that Nature takes to prevent the occurrence of vesico-uterine, the former would soon become as rare as the latter.

Antitoxin for Hay Fever.

The premature publication of expected results in a process of scientific investigation, whatever misconceptions and misrepresentations it may give rise to, has yet certain advantages. One of these is that it directs the inquiries of other observers in the same subject, and thus addsuce further facts which tend either to confirm or to contradict the hypothetical conclusion. For instance, when some months ago Sir Felix Semon
published some observations of his in the trial of Professor Dunbar’s hay fever antitoxin, it was thought, from the very inconclusive nature of his experiments that he was in somewhat unnecessary haste. However, there is no doubt that he interested many British physicians who would otherwise have been ignorant of Professor Dunbar’s researches, and reports from many of them are now appearing. On the whole, while it is still too early to give a decided opinion, the balance of evidence is in favour of the serum. For instance, in a recent paper, (a) Dr. Borromean, of Cuff, relates his experience in three cases, in all of which he believes the patient received benefit from the local use of the serum, while he thinks that its hypodermic infection produced in himself a certain degree of immunity. As, at any rate, the serum is quite innocuous, there is every reason why medical men should, wherever they have the opportunity, make further trial of it.

Diphtheria and its Bacillus.

That the Klebs-Loeffler organism may persist in the mouths of patients for many weeks after an attack of diphtheria has long been known, and the question always arises whether in such cases isolation is necessary. In some fever hospitals it is the rule not to discharge a diphtheria patient until a negative bacteriological report has been received, but in many cases this custom is impracticable. Usually the organism loses its virulence and becomes almost harmless (quite so to the patient himself), but one never knows what circumstances may cause a recrudescence of virulence so as to render it highly infectious. If one had any ready means of testing the pathogenicity of the organism it would be invaluable, but even inoculation, besides being too expensive for habitual use, is not satisfactory. For instance, in a case recently reported under the erroneous title of “Chronic Diphtheria,” inoculations of guinea-pigs proved fatal, while no infectivity was manifested, although many people were exposed to infection during the persistence for several months of the diphtheria bacillus in a patient’s throat.

The New Housing of the Working Classes Act.

According to a circular which has just been issued by the Local Government Board to the various town and urban district councils, it will be seen that several important amendments have been introduced into the law relating to the housing of the working classes. Under Section 32 of the Act of 1890, it has been the custom for the sanitary authority, upon receiving a report from the medical officer of health as to the unfitness of a dwelling-house for human habitation, to serve a notice upon the owner or occupier thereof to abate the nuisance before obtaining the necessary closing order. The procedure will henceforth be simplified by Section 8 (1) of the new Act, which will empower a justice to issue a summons for a closing order and the same to be granted without such notice having been served. In the event of a demolition order being made where there is non-compliance with the order for closing, the Council has hitherto been required to sell the materials and after deducting the expenses of the demolition to pay the balance of the money (if any) to the owner, but no provision was made under the old Act where the sale of the materials did not meet the cost of the demolition. Under Section 9 of the new Act, the Council may now recover the deficiency from the owner as a civil debt under the Summary Jurisdiction Acts, or under the provisions of the Public Health Acts relating to private improvement expenses. Though these innovations may appear somewhat drastic to the owner himself, yet it must be acknowledged that the interests of the public health will be truly served thereby. The responsibility of the medical officer of health in this matter will also be necessarily increased. The new Act cannot fail to stimulate the councils of boroughs and urban districts to exercise the considerable powers which they will possess under its provisions.

The Kaiser as a Surgeon.

We learn from an admiring American contemporary that the Kaiser has been able to add the record of another title successfully assumed to the many which he has previously adopted. Monarch, statesman, preacher, poet, sailor, soldier, critic, and universal admirable Crichton; he has now shown the world at large that he can also at need be a surgeon, and has taken suitable means that the knowledge of this fact shall be transmitted to posterity. A piece of tree-bark about eighteen or twenty inches long has been deposited in a glass case in the Hohenzollern Museum at Berlin, bearing the following inscription:—“Tree-bark with which his Majesty, the Emperor, improvised a temporary splint for the arm of her Majesty, the Empress, at the time of her accident in the Grunewald, March 27th, 1903.” We hope that his Majesty will confine himself to improvisations, and will not trust himself among the consequences that might result from attempts to establish a reputation by serious wanderings into medical science.

Poisoning by Tannic Acid.

The toxic effects of tannic acid, when taken internally, have usually been considered so slight as to be practically neglected, and no mention of this substance is made in many works on toxicology. Nevertheless, in an inquest recently held upon the body of a stoker who fell into a tanning pit in Bermondsey, the medical evidence was that the deceased, who was rescued from the pit and died later in Guy’s Hospital, had succumbed to an irritant poison, and, as an analysis of the bark liquor into which the man had fallen showed it to contain tannic acid, the conclusion was that the fatal result was due to its action upon the mucous membranes. It is understood that Dr. Stevenson coincided in this view. In virtue of its chemical nature tannic acid in large doses appears to lose its astringent properties, and then acts as an irritant in a similar way to other acids, though in a less degree.

(a) Scottish Medical and Surgical Journal, September.
In such a case as this the question of idiosyncrasy must be taken into consideration, as instances are known in which medicinal doses of the drug have produced irritating effects upon the various mucous membranes. The fact that many of the workmen in the tannery are said to consume bark liquor as a "pick me up," even in large quantities, only shows that they have gradually become accustomed to its action, but when an enormous amount is consumed at one time, the limits of toleration are exceeded, and its toxic effects then manifest themselves. The stimulating properties of this peculiar beverage are due not so much to the tannic acid as certain other vegetable astringent substances it contains, such as oak bark and acorn cup. The habit of drinking haphazard such fluids is not one to be recommended, and, similarly, the practice of "nipping" spirits, essences, and oils, frequently indulged in by other factory workers is to be equally condemned.

Formic Acid Production in Acute Rheumatism.

The evidences regarding the infective nature of acute rheumatism have been greatly strengthened during the last few years. It is now pretty well established that the disease is due to a particular variety of coccus, whether this be described as a diplococcus, streptococcus, or not. It has given positive inoculation results, thereby fulfilling the necessary criteria of a pathogenic organism. In the course of a recent paper communicated to the British Medical Journal by Dr. Ainley Walker, who has been working at the subject, it is stated that the appellation of Micrococcus rheumaticus appears to be more in accordance with the requirements of systematic bacteriology. In association with Mr. Ryfel, demonstrator of chemistry at Guy's Hospital, Dr. Walker has studied the pathology of rheumatism more especially from the chemical aspect, with a view to obtaining further evidence as to the production of acid in that disease. The same observers a short time ago came to the conclusion that it was not lactic acid which was concerned in the rheumatic process, and now the interesting statement is put forward that the micrococci produce formic acid in considerable quantity, and that this substance appears in the urine in appreciable amounts in rheumatic fever. The acid is not only present in the filtered cultures, but also in the bodies of the organisms themselves. Although the subject is still being pursued further, yet this fresh discovery is one of great importance, especially as it opens up the possibility of the explanation of the beneficial effect of the salicylates in acute rheumatism upon chemical lines.

Buffalo, had been in operation at Coney Island during the past summer, until the Society for the Prevention of Cruelty to Children caused the arrest of one of the proprietors of the incubator exhibit, for running a "baby farm." The case was brought before the Coney Island Court, and to decide upon the merits of the apparatus the Mayor appointed a committee of health officials, who reported that the incubator was doing good and should be purchased by the township.

Mammary Opotherapy.

In view of the uselessness of the majority of the medicaments and measures destined to determine an adequate secretion of milk in young mothers, it is interesting to know, on the authority of Dr. Prip, of Copenhagen, that the ingestion of cows' udders almost invariably accelerates and enriches the flow. The gland was given boiled, roasted, pounded or fried, but, unfortunately, however prepared, the patients often evinced great repulsion for this article of diet. If Dr. Prip's observations are confirmed it would be worth while to invent a means of exhibiting the gland that would be more acceptable to the patients, although, as a certain quantity must be taken, the problem presents some difficulty.

Tuberculosis in Cattle.

Butchers' associations are getting nervous in respect of the prevalence of tuberculosis in cattle, and we note that at a recent meeting held in Cardiff a resolution was unanimously passed that in future no stock would be purchased without a guarantee of freedom from the disease. If this example be followed the tuberculin test for tuberculosis will have to be resorted to on a much larger scale unless the vendor be willing to take the chance of the cattle turning out to be diseased when slaughtered. If strictly applied, the result must infallibly be a general rise in the price of meat, but after all, it is better to pay a slightly enhanced price than to run the risk of becoming infected.

Dr. Harold Scrufield has been elected Medical Officer of Health for Sheffield. A vacancy will therefore be created at Sunderland.

Sir John A. Cockburn, K.C.M.G., will deliver the Introductory Lecture at King's College on October 1st, taking for his theme "Imperial Federation and its Physiological Parallels."

Special Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

[from our special correspondent.]

Belfast.

The Water Supply.—The question of our water supply and its relation to the constant epidemics of typhoid from which we suffer is still a matter of general interest, and has been discussed with considerable warmth at meetings of the Corporation and Water Commissioners. Whatever the ultimate verdict may be, nothing but good can result from the free
ventilation of Professor Lorrain Smith's report, to which reference was made last week. The Public Health Committee, while emphasising the fact that the report holds the water as chiefly to blame, is paying some attention to such questions as drain testing, ashpit cleaning, milk vending, and the far too common practice of keepig pigs in the city. The chairman of the Belfast Water Commissioners, at the last meeting of that body, called attention to the report, and criticised its length. To that fact blinmed people, however, his statements will be largely discounted by the fact that he made a vigorous personal attack on Professor Lorrain Smith, accusing him of being prejudiced, partial, and unfair. His chief argument against the report was that typhoid occurred in all parts of the city, and not only where the Stoneyford water is supplied, and that sufficient precautions were not taken to prevent typhoid infection getting into the reservoirs from the cases occurring in the catchment area. He also stated that in the village of Dumurrury, which is now supplied with Stoneyford water, typhoid is no commoner than before that water was laid on, and that all the cases actually occurring had been traced to causes other than the water, such as bad drainage or infected milk. In a recent epidemic in Belfast, cases occurred in eight out of the twelve houses in an inquiry it was found that all of the eight received their milk supply from a particular dairy, from which none of the others were supplied. It was only to be expected that each of these public bodies would try to shuffle off its responsibility on to others, and that is simply a bluff, and they see quite clearly that they must really attend to their business a little better, and not merely talk.

CHLOROFORM FATALITIES.—There have unhappily been two fatalities with chloroform during the past week. In one case the patient was in a state of exhaustion from suppuration at the knee-joint, and an amputation was about to be done to give him a last chance. After careful consideration chloroform was chosen as the anaesthetic, but the patient died almost at once from cardiac failure. The other case was in hospital, chloroform being administered by a resident pupil for a minor operation.

Correspondence.

BOARD-SCHOOL DISEASES.

To the Editor of The Medical Press and Circular.

Sir.—With regard to some remarks in your article on "Board-School Diseases," the writer apparently has not realised the distinction to be drawn between board and board schools. "Ragged" and "granular lids," comparatively trivial in the latter, is of course a serious matter in the former. This confusion is common to many writers on ophthalmic work. A little experience of day schools as well as the hospital outpatient room, soon effectually removes it.

I am, Sir, yours truly,

JAMES KERR.

September 25th, 1903.

DISEASES OF THE HEART. (a)

This is a pretentious volume of 800 odd pages. The author treats his subject in a light and readable manner, which does not impress one with either weight of reasoning or high authority. "No claim is laid to originality, as is apparent from the numerous references to authors from whose works valuable suggestions and information have been derived." It would be well to do so, however, if they were the authorities referred to had been given, so that inquirers might go to the source direct, if they so pleased; but many of the names given as authorities are not of such world-wide reputation that the mere mention of their names guides one to their classic monographs. Some of the names snuggled up to each question are given, scarcely seem to obtain much dignity thereby, e.g., "the apex bruit in neurotic individuals is not infrequently vibrant or 'whizzing' (Drunmond) (?)" whereas for the time-honoured and realistic illustration of the appearance of a heart covered with pleomorphic cells, to "resembling the appearance produced by tearing apart two pieces of thickly buttered bread," no mention of Lennec, its author, appears. In fact, on reading through this book hardly anything is new, even men as Lennec, Corrigan, Stokes, contributed anything of importance to our knowledge of the heart, if we except Cheyne-Stokes' respiration and Stokes-Adam's disease. Lennec is mentioned a few (four) times in reference to unimportant points, and "Corrigan pulse" is also mentioned.

"The phraseology has been kept simple... the terms which are in most familiar use among American and English physicians." Many expressions are used which the latter, however, would hardly consider technical, and which some will think detract from the dignity of descriptive English. For instance, instead of "the density of the liver," "the flatness of the heart," where hepatic or cardiac dulness are meant; "the pulmonic sound being split," "the pulmonic sound being very brawny and slightly split," "the action of the heart was likened to rope jumping." Physical examination is dealt with very clearly and carefully, and many illustrations are inserted for making clearer special points alluded to. In the case of pericardial effusion, we cannot agree with the author on the great value of Rotch's sign. We admit that if it can be made out it may be the earliest recognisable sign of effusion, but the demonstration of its absence is not so easy as would appear from the text. The book description is all right if we are not dealing with an enlarged heart, but where there is slight hydrothorax, or the right side of the heart is, or may be dilated, the certain diagnosis of effusion relied on by this sign alone is to our mind unsatisfactory.

We prefer to follow Hilton Faggie in considering that the most important indication of the presence of fluid in the pericardium is augmented dulness first discovered at the base, viz., in the third left interspace. So much importance is attached to Rotch's sign, and the making out of straight or curved lines of dulness, that the great importance of the upward spread of dulness is not sufficiently emphasised.

Figure 29 represents the condition of a case on June 2nd. There was evidently a large pericardial effusion, reaching up to the second rib, which was subsequently absorbed, for on June 24th an autopsy revealed extensive soft, recent adhesions. It is evident, however, that this effusion was not recognised, owing, perhaps, to Rotch's sign not being made out. The case has been given as illustrating acute endocarditis. Again, Figure 62 represents a large pericardial effusion reaching to the second rib, but though the relation of this case occupies eight and a-half pages, there is no mention of either its presence or absence. There was hardly a post-mortem examination, but the rapid cardiac failure, with late oedema quickly increasing, while "the urine was always remained negative," is strong support of the inference we have drawn from the diagram.

"Special attention has been paid to treatment."—Nearly 100 pages are devoted to the treatment of heart disease, and it is not altogether agreeable with both in the various phases and with respect to habits, marriage, climate, use of drugs, &c. We must confess, however, that we consider that too great prominence has been given to treatment owed to Schott's treatment. No work of the kind would have been complete without a concise account of these methods, but several pages of letterpress and nineteen illustrations of the graduated or resistance exercises advocated by Schott give that treatment a prominence.
of which it is not worthy. Baths, too, whether taken at Nauheim or at home, hardly deserve the importance they are given. Does any scientific physician honestly believe that "water containing 10 per cent. of sodium chloride and 1-10th per cent. of calcium chloride" (p. 465) will cause "increased tissue change, together with reflex stimulation of the heart, which causes its slower and more powerful contractions, and with a physiological stimulation of the arterioles and capillaries by the passage of the gas and salts through the skin" (p. 467, italics ours)? Why not add to the writer's evanril and sugar and so have nourishment as well?

The writer frequently illustrates special points—mostly in dealing with treatment—by relating cases which have occurred in his own experience or practice, and in most instances these illustrations are very strikingly and clearly given. By going into details of the treatment of special cases he, however, lays himself open to criticism which we all know is more free and general on the subject of treatment than on almost any other. He evidently has great faith in cathartics; he says "the success of such treatment depends not alone upon its vigour, but also upon its persistent course. DAY after DAY, till the upper hand has gained over the dropsy." In reading over one case—which occupies eight and a half pages—we find these precepts were carried into practice. It was a case of ascites complicating second and terminal peritonitis, and we read that on one day (Tuesday, apparently) "cathartic was ordered," and he had "half a dozen cathartics" on the Wednesday morning, in spite of the patient's condition being very far from a worse." "Thursday came. . . . More bowel movements of a watery character were secured without any impression on the stasis." He died about 10.30 that night (p. 317). The author says (p. 402): "This proved the necessity of suitably adjusting the dose on the ground that the cardiac sufferer is too weak to endure depletion. As a matter of fact the patient's weakness is due to his circulatory embarrassment, and experience teaches that in being entirely surprised the degree a healthy individual would be by the purgation, the cardiopathy actually finds he feels stronger so soon as the primary effect of the catharsis is past." For our own part, we agree with the above objections. We are convinced that, though robust, half-a-dozen watery stools in a forenoon would have a depressing effect, and this repeated three days in succession would certainly cause us very considerable weakness. How such an effect on a healthy individual could be transformed, so as to make an advanced cardiopathy feel stronger, passes our comprehension, and our experience is, that it does not.

The subject, "heart pain," considered apart from angina pectoris, is treated in three-quarters of a page. It is a subject that deserves more attention, but it requires a great and ripe experience to deal with it in its various bearings. To most students and recently qualified men cardiac pain means angina pectoris, or it means nothing.

The book is profusely illustrated with diagrams, pulse tracings, skiasgrams, and photographs of various morphic conditions of the heart and vessels. But it is not one with originality in research or teaching.

As with most American publications, the book is so heavy that it must be read at the table, which the high-priced surface of the paper renders distressing to the eyes. Some material or substance used in the binding or printing has pervaded the book with a strong, and most unpleasant odour.

LIFE AND LABOUR OF THE PEOPLE IN LONDON. (a)

Mr. Charles Booth's epoch-marking work finds a worthy conclusion in the present volume. Seventeen years and an equal number of volumes have been occupied in this monumental production. Not only have the researchers themselves proved of exceptional interest and wide service, but they have done much to awakening the conscience and intelligence of many thinking men and women to the problems of our metropolitan life. The living conditions and habits of people are constantly changing, and the conclusions of Mr. Booth are still far from dateless. The book is divided into two parts: (1) The Social Studies: and (2) The Material Life of the People. Every chapter teems with suggestive notes. We have careful comparisons of poverty and crowding, birth-rate and death-rate, and poverty and health. The ways of the masses are portrayed with truth, discernment, and luminous descriptions are given of their customs and manners, habits and fashions. Much light is thrown on such matters as marriage and morality, the use of holidays and amusements, eating and drinking, and the various economic conditions of life. Important sections deal with public-houses and licensing, prostitution, and police and crime. The medical reader will be particularly interested in the chapters on the organisation of charity hospitals and nursing; the latter, however, being all too meagre for an adequate presentation of the subject.

A very valuable feature of this volume is the convenient abstract of the contents of the complete work, which with its seventeen volumes forms quite a little library. An interesting map of London is given, showing the distribution of churches, schools, and public-houses, all most important factors in the evolution of the people.

We have nothing but admiration for Mr. Charles Booth and his coadjutors in this remarkable investigation, but we cannot but feel that a much nearer approach to the true meaning of many perplexities and problems in which the physical element necessarily looms large would have been attained if the intimate cooperation of specially experienced medical men had been sought. In spite of limitations and many shortcomings, the work is a monumental one, and all who love to play a part in useful service for mankind should study it with discernment. We particularly commend the concluding volume to all medical men.

MESSRS. J. AND A. CHURCHILL announce for early publication a new (the sixth) edition of Dr. Galabin's "Manual of the Diseases of Women." The work has been greatly enlarged and contains twice as many illustrations as in the previous edition, viz., 284. The same firm have also in the press new editions of Dr. lettuce's well-known books on midwifery and gynaecology. The latter will be much larger than before, and be profusely illustrated.

ANTIPHLOGISTINE.

The Denver Chemical Manufacturing Company have submitted to us a sample of a product called antiphlogistine. This is a grey paste which, when spread over the skin of an inflamed part, exerts a resolving and anodyne effects tending to promote the subsidence of local inflammatory mischief with relief of pain and swelling. It is not greasy, does not stain linen, and is intended to be left in situ for at least twenty-four hours, when it can be peeled off easily enough. Anti-
phlogistine is a smooth homogeneous mixture of several chemical substances, the base being the silicates of alumina and magnesia in intimate alliance with pure glycerine, while the antiseptic property is conferred by the presence of boric and salicylic acids. There are, in addition, other ingredients which in our opinion combine to render this preparation well suited for the purposes for which it is designed.

This preparation has met with success in America as a local application of great value in various classes of cases. We have given it a careful trial, and we have satisfied ourselves by analysis that its composition corresponds with the ingredients stated, and that its beneficial therapeutical effects are such as to render it a valuable adjuvant in the treatment of localised inflammatory and certain other conditions.

CHELTINE: A SOLUBLE MALTOSE FOOD.

We find on examination that, as claimed, this food is practically all soluble in water, and is free from woody fibre and from starch, both substances but too often present in foods intended for infants. The sample submitted to us yielded, on analysis, the following results:—Moisture, 4.5 per cent.; nitrogenous matter, 8.0 per cent.; fat, 1.0 per cent.; mineral matter, 2.6 per cent.; the remainder consisting of sugars (chiefly maltose) and soluble carbohydrates.

The directions given are that milk should be used in preparing the food for children, which is scientifically correct, inasmuch as the addition of milk provides the due proportion of fat which is at present lacking to make the proper balance of constituents for a correctly designed infant’s food. The food is sterile, it would apparently keep good for any length of time if closely stoppered. Unless corked tightly each time it is used, it absorbs moisture from the air, but not so rapidly as to entail any serious detriment to its value.

This food fully complies with the standards for infants’ foods, set forward by Mr. C. G. Moor in his work on “Standards of Purity for Foods and Drugs.”

FERRUGINOUS TABLOIDS.

MESSRS. BURROUGHS WELLCOME AND CO. now prepare a tabloid product containing soluble iron phosphate (gr. ij.) with soluble hyposulphite of iron (gr. j.)—a useful combination suitable for administration in cases of neurasthenia associated with anaemia, and generally as a ferruginous tonic. The tabloids are sugar coated, thus ensuring their inalterability.

QUININE SALICYLATE TABLOIDS.

The salicylate of quinine is a salt which has of late come into favour in rheumatic and neuralgic affections. As it is also an excellent tonic, a tabloid containing only one grain of the drug is now prepared.

SOLOID ROMANOWSKY STAIN.

The Romanowsky stain (Leishman’s powder) is the most recent addition to the useful series of “soloil” microscopic stains. The soloil product is dissolved in to cc. of pure methyl alcohol for use in staining blood films, the characteristic red tint being brought out by dropping distilled water on to the film under examination. Each tube contains six “soloil” products.

New Instruments.

AN IMPROVED MOUTH GAG.

Suggested by Dr. COLE-BAKER.

This instrument is made in the form of a forceps, the front ends of which are fitted with grooves to fit on the gums or teeth. The invention consists in making the front limbs with two pivotal joints so arranged that when the gag is fixed in the mouth the handles can be bent out of the way by the operator. Many mouths, from absent teeth on upper or lower jaw, offer great difficulties for the ordinary gag. With this invention there is no mouth in which a suitable position cannot be found. When fixed it will allow of operating on either side, the handles being bent well out of the way. The handles of the instrument are so slender that with the ordinary face-piece, gas can be readily given for the extraction of teeth, allowing the operator to rapidly pass from one side to the other by simply turning the handles laterally on their pivotal joints. The instrument can be most readily inserted by holding the last phalanx of the limbs between finger and thumb with the ends of the fingers pressed against the ends of the grooves and thus steadying them with the handles resting in the palm of the hand. This can be done with one hand, while by the other the handles are squeezed together in order to open the limbs sufficiently, these being held in proper position required by means of a ratchet arrangement.

The gag is made by Messrs. Arnold and Sons of London, and can be used for removal of tongue, adenoid tonsils, cleft palate, and all laryngological operations—in fact, for every use of all other gags except that of forcing the mouth open.

Obituary.

DR. JAMES RAVERTY, OF BRAY.

We regret to announce the death of Dr. James Raverty, of Bray. He was medical officer of the Bray No. 1 dispensary district, and medical officer of health for the borough. He belonged to a medical family which for the past seventy years were resident in the town. His practice was large and remunerative, for he was not only successful as a physician but was possessed of the secret of inspiring and retaining confidence.

MR. ALBERT CHARLES QUEELY.

MR. ALBERT CHARLES QUEELY, a Fleet-Surgeon of the Royal Navy, retired, died on Wednesday of last week at the age of fifty-five. During the war between Chili and Peru, 1879-1881, he, as senior officer of the “Triumph,” the British flagship on the Pacific, was detailed for duty at the hospitals at Lima to aid the sick and wounded during the course of hostilities, for which services he received the approval of the Admiralty, and also the thanks of the Provisional Government of Peru.
Medical News

Plague and Cholera.

Both plague and cholera are raging at Peitang, 2,000 deaths having occurred during the last two months. The present mortality averages fifteen daily. The epidemic of plague at Rio de Janeiro shows no signs of abating, and there have been ten deaths during the past week.

University of Durham.

The following candidates passed the Second Examination for the Degree of Bachelor in Medicine during the September examinations in Anatomy, Physiology, and Materia Medica:

Honours—First Class.—Lewis Augustus Catterluck, L.R.C.P., and S. Ed. and I.

Honours—Second Class.—Vincent E. Badcock, Florence B. Lambert, Frederick C. Fylus, Neville A. Eddlestone, Richard W. Swain.

The following candidates passed the First Examination for the Degree of Bachelor in Medicine:

The following candidates passed the Third Examination for the degree of Bachelor in Medicine:

Honours—First Class.—Lewis A. Clutterbuck, L.R.C.P., and S. Ed. and I.

Honours—Second Class.—Olga A. Schiele, Reginald I. Douglas.

Society of Apothecaries of London.

The following candidates passed (September, 1903) in:

Surgery.—W. V. Braddon (Section II.), W. H. Bush (Sections I. and II.), K. R. Jay, A. Jurriaanse (Sections I. and II.), P. S. Kloots, L. W. Roberts, S. H. Ryan (Sections I. and II.), A. Turner (Section II.).

Medicine.—J. E. L. Bates, W. H. Bush (Sections I. and II.), L. E. Ellis (Section II.), A. H. Falkner (Section II.), A. Jurriaanse (Sections I. and II.), N. O. Roberts (Section I.), F. Robinson (Sections I. and II.), S. H. Ryan (Section I.), F. J. Waldmeier, J. W. Watson (Section I.).

Midwifery.—W. B. Harris, A. Jurriaanse, R. Reynolds, F. Robinson, S. H. Ryan, A. Williamson.

The Diploma of the Society was granted to the following Candidates, entitling them to practice midwifery, surgery, and midwifery:—J. E. L. Bates, L. E. Ellis, and A. Jurriaanse.

Dr. Louis Parkes has been appointed to succeed the late Professor Corfield as Consulting Parliamentary Adviser to his Majesty's Works and Public Buildings Department. Dr. Parkes is lecturer on public health at St. George's Hospital.

Central Midwives Board.

A meeting of this Board was held at the Board Room, Suffolk Street, Pall Mall, London, on September 24th, when the following business was transacted:

(1) Dr. D. was re-elected chairman of the Board until the first meeting in the month of April, 1904. (2) A letter was read from the Clerk of the Council enclosing a sealed copy of the rules as approved by the Council, August 12th, 1903. (3) The secretary reported that the rules and forms were printed and ready for publication, and were on sale at Messrs. Spottiswoode and Co.'s, Limited, 54, Gracechurch Street, E.C., and 5, New Street Square, E.C. Prices: Rules (paper covers), 6d., post free 7d.; (stiff boards), 8d., post free, 9d. Forms, 1d. each. (4) The secretary was instructed to complete the registration of the rules and forms, so as to preserve the copyright. (5) A letter was read from the hon. secretary of the Manchester Southern and Maternity Hospital enclosing an application for a recognition as a training school for midwives under the regulations of the Board. The further consideration of this matter was adjourned, and the secretary was instructed to ascertain mean while whether the application of the hospital included a request for the recognition of their certificate as a sufficiency qualification under Section 2 of the Act. (6) Applications were received from registered medical practitioners for recognition as teacher under Section C (3) of the rules. The secretary was directed to obtain further particulars from the applicants. (7) Several applications were read from ladies desiring to be trained as midwives at a nominal fee. The secretary was instructed to refer any such applicants to the Association for Promoting the Training and Supply of Midwives, 29, Buckingham Street, Strand, where all information relative to the training and work of midwives might be obtained. (8) It was unanimously resolved, on the motion of Mr. Parker Young.—That the best thanks of the Central Midwives Board be and are hereby given to the Privy Council for their kindness in placing office accommodation and the use of the Board Room at the disposal of the Board during the time they were without offices." (9) The "Suggestions to County and County Borough Councils " as to the working of the Act (including the delegation of powers) were further considered and amended. The secretary was instructed to inform the county councils that the suggestions would, when finally approved, be forwarded to any council desiring a copy.

King Edward's Hospital Fund for London.

It is proposed to create a "Shopping Day" in connection with the King Edward's Hospital Fund for London, and to endeavour to make it a record one for all classes of shops in London Joining the scheme. The day fixed is the first Tuesday in November next. It is hoped that those joining the scheme will benefit by the advertisement and publicity given them, and that they in return will be willing to contribute a percentage of their takings on that day to the London hospitals. The King and the Prince of Wales, as patron and president of the fund, have signified their approval of the movement, and a number of well-known proprietors of retail establishments in the West End and City have already intimated their intention of supporting it.

The North London Medical and Chirurgical Society.

At the next meeting which will be held in the Board Room of the Great Northern Central Hospital, High Holborn, on October 8th, at 9 p.m., Professor R. T. Hewlett will read a paper on "Insects as Carriers of Disease." The attendance of medical practitioners is cordially invited.

English Hospital at Venice.

A new English hospital has been opened on the Giudecca Island, Venice, by Princess Christian, who was accompanied by the Princess Elizabeth of Saxony. This foundation, which supplies a long-felt need, is due to the benevolence of Lady Layard.
Jersey General Dispensary and Infirmary.—Resident Medical Officer, Salary £120 a year, with rooms and meals, applications to Honorary Secretary, Infirmary, Jersey.

London County Asylum, Bainton, Corporation, N.S.W.—Senior Assistant Medical Officer, Salary £150 per annum, with board, furnished apartments, and washing. Applications to J. W. Partridge, Assistant Committee Office, 6 W. Drury Lane, London, E.C.2.

Manchester Children’s Hospital, Pendlebury.—Medical Officer, Salary £200 per annum, including board, furnished apartments, and washing. Applications to J. W. Partridge, Assistant Committee Office, 6 W. Drury Lane, London, E.C.2.

Parish of Birmingham.—District Medical Officer, Salary £300 per annum, including board, furnished apartments, and washing. Applications to J. W. Partridge, Assistant Committee Office, 6 W. Drury Lane, London, E.C.2.

Southampton Incorporation.—Resident Assistant Medical Officer, Salary £200 per annum, with apartments, rates, washing, and attendance. Applications to David P. Griffin, Clerk's Office, Workhouse, Southampton.

Warwick County Asylum, Hatton, near Warwick.—Third Assistant Medical Officer, Salary £120 a year, with board, lodging, and washing. Applications to the Medical Superintendent.

**Timeline and Events**

**Meetings of the Societies, Lectures, &c.**

**Thursday, October 8th.**

**The British Gynaecological Society**—Will meet this evening. (Specimen.)—President.—(1) A Case of Carcinoma of the Uterus, by Dr. Maughan-Jones—Most likely to be Gland by means of Epithelium, and other specimens illustrating cases. Dr. Macrahan-Jones.—(2) Notes on a Case of Carcinoma of the Uterus, by Dr. A. H. Henderson—Excessive Obstetrical labour after Hysterectomy. Dr. Henderson, Incorrigible and Irreducible Perineal Horrible in a Woman.—Instrument. Dr. Maughan-Jones, Peritoneal Knife.

**Appointments.**

**Cross, John, M.B., Ch.B., Glasc., House Surgeon to the Victoria Infirmary, Glasgow.**

**David, Edward Sandon, MD, L.R.C.P., L.S.A., District Medical Officer by the St. Austell (Cornwall) Board of Guardians.**

**Eckard, W. McLean, M.S., L.R.C.P., F.B.R.S., Eng., Joint Lecturer on Anatomy at St. Bartholomew's Hospital.**

**Geoghegan, Francis J., M.D. Trinity College, Dublin, Resident Medical Officer to the Victoria Central Hospital and Wallasey Dispensary, Liscard, Cheshire.**

**McKellar, William A., B.A., R.C.P., &c, Medical Officer, Dupont of the Poplar Union.**

**Norman, R. H., M.D., Lond., B.A., M.R.C.S., L.R.C.P., Amnesthetist to the Hopital Royal Infirmary, Glasgow.**

**Russell, James, M.B., Ch.B., Glasc., House Surgeon to the Victoria Infirmary, Glasgow.**

**Smith, M. Stew., M.R.C.S., L.R.C.P., Lond., Assistant Medical Officer to the London Temperance Hospital.**

**Vacancies.**

Belmullet Union, Knocknawler Dispensary District.—Medical Officer’s Salary £170 per annum. Applications to E. N. Fryan, Belmullet (Radio).—Aids to the Sick.

Bradford Poor Law Union.—Resident Medical Officer for Sanatorium. Salary £120 per annum, with rooms and meals, and washing. Applications to Thomas Crowther, 2 Manor Row, Bradford.

Cheltenham Union.—Medical Officer. Salary £175 per annum. Applications to the Chairman.

David Lewis Northern Hospital, Liverpool.—Matron. Salary £110 per annum. Applications to the Chairman.
Original Communications.

A GLIMPSE AT SOME OF THE DEFORMITIES AND DISEASES OF WOMEN DUE TO CLOTHING.

By W. WILLIAMS, M.D., M.R.C.P.

Hon. Physician, Royal Southern Hospital, Liverpool.

In the beginning of 1892, I published in the Liverpool Medico-Chirurgical Journal an article on the disease known as chlorosis. In that article I pointed out the probable connection between this disease and tight costume.

In my contribution to these reports it is but fitting that I should again refer to the practices prevailing among women with reference to their clothing, and to the consequences resulting from these practices, as they are responsible for the largest class of ailments I have to deal with in the female medical wards of this hospital.

In the above-mentioned article I endeavoured to show that chlorosis, in some degree an almost universal complaint among young women, was the simplest of all forms of anaemia, that due to hemorrhage; that this bleeding took place in the stomach, that it was derived from a gastric ulcer, and that the gastric ulcer was in its turn produced by the stays, or, in other words, by wearing about the waist a tight, unyielding, constricting mechanism which compressed the liver and stomach, disarranged their circulation, and—as further explained—produced the lesion in question.

Practically every young woman loses blood in the way indicated, and, as a consequence, becomes the prey to anaemia more or less marked; the worst cases of anaemia from this cause occur not in those whose figures have been systematically trained by the stays from infancy, but in those who from previous neglect are taken in hand later in life, and more hasty and violent measures resorted to, as is the case with the poorer classes.

In an ordinary case the change shows itself shortly after the final alteration or evolution as regards dress of the girl into the woman, from the 16th to the 18th year, but the exact age will necessarily vary with the tastes of the mother. Stays, in some form or other, are worn from infancy in nearly all the cases where they are used, but up to 16 or so, except in a certain proportion of cases, the victim has only been broken to tolerate the stiffness and feel of the thing; growth, therefore, is, we find, fairly advanced in most cases before the anaemia supervenes, before a very injurious degree of pressure comes to be applied. It is consequently, as a rule, not the building up of the frame, but the building of that more important edifice, the constitution, that is most interfered with. This work, which may be defined to be the maturation of the frame, organs and their functions, is a work with which we all become occupied after the period devoted to growth is over, and which of necessity takes some years to accomplish.

There can be no doubt but that constitutionally the average young woman is far behind the average young man, and that with increasing age the difference between them becomes more and more marked. The powers of the system in those who have suffered from the ill-effects of stays do not appear to be vigorous enough to
be sufficiently sustained to accomplish both purposes—the effort made to build the frame seems to exhaust it. And we must all readily admit that to be without healthy digestion and without healthy blood from 24 to 30, which is now the case with most, with nearly all, young women, especially with those who are of a very fashionable turn themselves, or whose mothers are of that degree or persuasion, is to arrive at the latter age in a very deplorable condition, without a constitution, without, in other words, that which we all have to rely upon to secure us an enjoyable existence, and to ward off from us invalidism, premature old age, and decrepitude. Some apology for a constitution may no doubt with reform be acquired after thirty, even though reform after this age is necessarily a rare contingency and one difficult to accomplish, and to compare a constitution obtained by such late repentance with one secured by healthy habits all through life would be to compare things of a very different quality.

The lives of women, and the functions and responsibilities belonging to them, require that they shall have strong, robust constitutions, and it is besides no less essential to them that it is to the rest of the animal kingdom that their anatomy should be normal, the and worse condition; and she avoids almost invariably injuring the vital parts; we see, for instance, that the spinal marrow escapes injury in most instances of disease of the bones which leads to curvature of the spine, and the normal or relative size of the base of the chest as gauged by the amount of diaphragm action that is present in any case is, so far as my experience goes, never interfered with in cases of deformed chests from disease, or from causes other than voluntary interference except in hypertrophic emphysema. Are all departures from the normal chest—excluding those that are voluntary—always compensatory, and so never present without altered lung capacity, spinal disease, or some other disease, condition requiring an alteration in the shape of the chest as a contribution to aid recovery?

In hypertrophic emphysema, with an increase in the lung volume and in the size of the thoracic angle, there is a marked decrease in the lung function and in the action of the diaphragm.

The few cases of deformity of the chest due to Pott’s curvature that I have so far examined have all of them shown a great increase in the size of the thoracic angle, but as the increase was not associated with a lessening of the action of the diaphragm in any of these cases, it

No. 3.—A girl, aged 14, convalescent from typhoid. The thoracic angle, marked as in the other cases with a chrome pencil before being photographed, was in this case found to be a little more than a right angle. The size of the thoracic angle, normally about a right angle, is an accurate measure of the area of the base of the chest in most cases. Respiration was abdominal. By the aid of the X-rays the movements of the diaphragm were measured and found to be 2½ inches. This is a good example of a normal chest with normal respiration.

Parts allowed to remain in their normal positions; whereas the present practice that prevails so largely is to push a stomach into this out of the way corner, and a liver, or some other equally ignored organ, into that anywhere in fact, so long as place is made for the waist, a voluntary deformity of as undesirable a nature surely as any that ever originated in thoughtlessness and ignorance, and compared, or side by side with which, many an unavoidable deformity due to disease would, but for the depravity of taste, which faulty education has brought about, be a more acceptable contemplation. Nature has always a merciful design, her deformities are for the purpose of curing or improving some other

No. 4.—A strong, active woman, aged 40, by occupation a vegetable-cook; admitted for influenza. Thoracic angle appeared normal; breathing abdominal, ample and free. Had not worn stays as a child; had tried to do so later in life, but for long, as she could not do her work with them on, may be a compensation to an encroachment on the area of the base from some other direction.

Whilst it is the case that the corset is the author of the worst evils humanity owes to its vices, it is true also that there are other habits, with reference to clothing, that lead to deformities equally pernicious morally, though applied to regions of less immediate importance vitally. In China, for instance, we know that it is a custom for all women, except those of the very lowest class, i.e., those who work, to have the natural growth of their feet stopped at an early age. In other countries, and the fact is made abundantly clear to us in ours, it is a custom for the women as a whole, or very nearly as a whole, to have the natural development of their waists, chests, breasts, and backs diverted into deformity, with muscular and glandular atrophy, also at an early age. Either of these two practices—the one has no more to recommend it than has the other, beyond the fact that the Chinese woman meddles with a less important part than do her sisters in other countries—were they adopted as generally by
the male population of any country, would insure the extinction of the race to which it belonged as an independent people, and a lapse of it into slavery as certainly and as quickly as would a combination of all the vices that have ever been instrumental in destroying nations in the past. Bearing in mind its powerful moral influence as well as the cause of retrogression can be more rapid than that produced by, or arising from, a loss of bodily health from vice.

Most vices promise, and indeed afford, at all events for a time, a period with pleasurable sensations; these are the return, the set off, against the hosts of drawbacks inseparable from vice always. It is possible, indeed it happens in most cases of vicious habits, that the drawbacks are seen to so far outweigh the apparent advantages that the game ceases to be considered, so to speak, worth the candle; under these circumstances the victim may reform, and so return to what he knows to be a better and more enjoyable state of existence. Before such a result as this can ever become possible, however, it is clearly necessary that the backslider, of whatever sort he may be, should have the materials at hand wherewith to form a judgment, that he should know experience, at hand whereon to found a judgment—the habit is imposed upon them at such an early age that they can have no knowledge of a previous natural condition to guide them, they are brought up artificially in a bad faith, they do not know what is right from what is wrong in this respect, the faculty of natural appreciation is here in abeyance.

It is evidently under these circumstances, with the loss of the initiative in the individual, that the necessity arose for the establishment among us of a custom for general guidance. This has developed into a vice, and the practical outcome is the strict and rigid conventionalism which we see prevailing in the present day in regard to female dress and habits, with its effects, moral and physical. If pride of figure and pride of style are based on a false foundation, one composed of artificial moulding in one region and of padding in the next, there is instituted a wrong moral teaching, which is always detrimental to mental health.

Conventionalism is now the reigning authority, the deity to whom the female form, and the female life as well, are sacrificed. Conventionalism, always an eloquent confession of individual ignorance and insuf-
for women, to the cultivation of tastes for athletics and for manual labour, which, though as yet so generally ignored, may be dangerous to one sex, can be disastrous to no one, provided its neglect, as it only means leading a natural and healthy life in place of one of an opposite kind; in fact, in the direction and with the aid of these the healthiest influences, moral and physical, that can be brought to bear upon human existence, whatever the state this may be in. Let us wish all speed to these agencies, and congratulate ourselves upon the fact, as I think we may, that they, but more especially the first and last, are more in contention in the present sphere, with ignorance, prejudice and credulity, their natural enemies, than they have in the case of women ever jointly been before, probably.

Deformity due to Clothing.—The first of these to appear is lateral curvature of the spine. In this deformity, the spinal column assumes the shape of the letter S reversed, with the upper curve to the right, and the lower to the left. Briefly, of course, it gives rise to inequality in the height of the shoulders, to a projection, a growing out of the right shoulder-blade behind, and to an ungainly figure generally.

Cause of Lateral Curvature.—In the natural exercise of the spine preserves its normal form, or lines, by means of its beautifully arranged and most delicately balanced muscular system; being a flexible column, having so many joints at such short intervals, such a system is essential to it—one set of muscles, designed to exactly counterbalance the opposite. It can readily be imagined how easily such a system can be deranged by any interference. Boys are allowed full freedom to retain this mechanism in its highest perfection, and their freely active lives enable them to go on developing this system of muscles to its full extent; consequently, we never see boys with lateral curvature of the spine properly so-called. The case of the girl is different: she has to wear supports to her spine from infancy; this support presumes to supply the place of the delicately balanced muscular system already alluded to, which Nature has provided for the spine. That it is a great deal less fit to do this than a wooden leg to compete with a real one can readily be gathered from the fact that the muscular system of the spine is infinitely more complex than that of the leg; moreover, artificial support to any part means that the natural support provided for that part will waste away, in other words, every structure, organ and function in our bodies must be kept in normal activity, must be frequently worked in a proper manner, or it will lose its ability.

Nothing produces a straighter or better-shaped back than does the special use the muscles of this part are put to when a weight is carried on the head, though this use is not so much a special use as it is an exaggeration of the function of the spinal column itself. The spinal column with its muscles forms the only prop between the head and pelvis, and this has to be kept more than usually rigid to support the extra weight, and a great deal of muscular power is also made use of, and made use of in the best way muscles can be used in preserving the balance, i.e., antagonistically; no muscle or set of muscles can in this way develop in excess of their opponents. It is, no doubt, the necessity there is for a proper balance during progression under the conditions of increased difficulty which prevail when a weight is carried on the head that leads to such an equal development of the intrinsic and other muscles related to the spine as to result in the beautifully straight backs we are familiar with in basket women.

The next deformity that I shall allude to may be called the "ewe-neck." This is commonly seen in women, especially those who, from choice or necessity, have been very fashionable, and who have commenced to be so at an early age. Accompanying this deformity, and characteristic of it, is a hump in the dorsal region behind the shoulders. The ewe-neck itself is a congenital complication at the nape of the neck such as is present in sheep, the reverse, in fact, to an arch or crest.

Cause of the Ewe-Neck.—Its production may, I think, be accounted for in the following manner—the head, face included, is attached to the spine eccentrically, and consequently the weight is carried on the spine at the back of the neck and not on the back of it. This, we find in the human subject, is supplied by the upper extremities, shoulder-blades and arms, which are attached to the head behind by means of the trapezius muscles. These, then, act as counterweights, help to keep the head level. But to do this effectually the shoulder-blades must be allowed to hang free, and also to hang well behind, so that the line of pull may be at right angles to the transverse axis of the head. Where the above conditions are not fulfilled, and where the shoulder-blades come to be supported, and as mostly happens they even come to be pushed up by the upper parts of the stays, their influence as weights is destroyed and the muscular attachment to the head, forming normally the nape of the neck, being no longer in use, wastes, and a hollow concavity—the deformity in question—is created at the back of the neck of the shoulders; at a higher level than the normal one, with a forward inclination of the neck and a cocking up of the chin, the latter made necessary under these changed conditions to prevent the balance of the head, tend to accentuate the peculiarity.

Next Deformity.—The chief of the deformities which I have to refer to is the waist, a contraction of the area of the base of the chest brought about by pressure applied to the lower ribs, by means of which they become eventually deformed and fixed in an altered and false position. This deformity, as is abundantly proved by the extent of it which is met with in the majority of middle-aged women, results in the most serious manner in very many cases be started at a very early age, in fact, while the ribs are still soft and capable of readily yielding to pressure; up to twenty or so, by reform aided by muscular exercise, much of the evil may be undone, but at twenty-four, or soon after, my experience is that it has become permanent.

In addition to the intercostals, latissimus dorsi, serrati and pectorals, which are affected through being so bound down by the stays that they cannot be used, the special muscle involved here is the diaphragm; this, next to the heart itself, is the most important muscle in the body—the breathing muscle. The diaphragm, besides playing the important functions of the abdominal organs, to which the importance of its influence as a propelling force it would be difficult to exaggerate, plays the chief part in the functions of the lungs, which will consequently suffer as a consequence of its restricted area, and integrity of this muscle. When the area of the base of the chest is reduced in size the action of the diaphragm is lessened in exact proportion to the amount of this reduction, because, by the approximation—a gathering together of its attachments to the lowest ribs—it is made too slack for a contraction to be effective in producing the piston-like descent which is characteristic of the work a normal diaphragm has to do. When the stays are on the tension below also comes into operation as a preventive.

The abdominal wall muscles that have attachments to the ribs or to their cartilages are affected in the same way, only in a lesser degree, as the diaphragm is, i.e., their attachments are approximated in all cases where the area of the base of the chest is lessened.

In very many women, then, the function of this all-important muscle is seriously impaired to intents and purposes annihilated, and they consequently never use it at all, but while the stays are on, but create instead an artificial way of breathing for themselves, with the upper part of the chest. This part in them, as is amply evident when any uncut dress is worn, performs the natural act of the discarded diaphragm. This thoracic variety being quite an unnatural way of breathing, must, in common with all things that are unnatural,
fall short of the requirements and demands of the original design; and therefore, it is said to mark the wants of a vigorous constitution. Thoracic respiration by itself is artificial, and supplementary to all human beings, men and women alike. In children of both sexes a normal variety of thoracic respiration prevails invariably. We see men made dependent upon, and compelled to resort to, thoracic respiration alone only in certain diseased conditions, as, for instance, in hyperpyretic emphysema, where the diaphragm has already become involved, to its function, and it is that position by the enlargement of the chest and lungs which characterises that affection, and we see thoracic respiration prevailing in other diseases, acute most of them.

As related in the article already alluded to, compression of the waist, and in this compression is included two-thirds of the chest and abdomen, interferes also with the functions of digestion and assimilation, leads to dilatation and ulceration of the stomach, atrophy, attenuation and dilatation of the abdominal walls with their accompanying evils, of which hematemesis, anemia, dyspepsia, &c., are a few of those that are most familiar in everyday practice. I have seen cases where dilatation of the heart was present, the direct result, I thought, of exercise under the conditions of lessened lung space and breathing capacity.

Not all evidence before us, it can scarcely be necessary to ask ourselves the question: Why does a woman get old sooner than a man? The latter at seventy and over can do his day on the hills or at the river, and only very occasionally have to fight hard in detail.

A woman, on the other hand, is, in the majority of instances, permanently crippled as to her skeleton at twenty-four, and permanently crippled as to her muscular system by the time she is thirty. Those who will not subscribe to this statement, let them ask themselves the question: How many women are there who can go even for a long walk without their statin, or more than a short hop without the crutches? and they will find that these views are not unfounded on well-known facts. That this process of crippling and deformation is conducted under the sway of ignorance is proved by the fact that the most deformed are considered the best figures, and are advertised as such, along with the most effective stays, in all the foremost journals of fashion, and that all natural figures are viewed with abhorrence and disgust when they are met with. They are therefore met with, and we know besides that it is alone the unlimited nature of the vicious mental effects of vice long indulged in that can make such a state of things possible.

It is certainly not a prevailing rule in the animal kingdom generally that the females are less able-bodied than the males, and we know that in some classes the females actually exceed the males in bodily strength as well as in size, as in the falcon tribe, for instance.

If all children, irrespective of sex, start even, as we see they do, what but a change in their later habits and mode of life can lead to the great disparity that eventually creates such a gap between them as men and women?

Any effort made to remove this difference does but seek to increase the happiness of both sexes, by indicating the way partnerships between them could exist on more equal terms than at present prevail, and to show that women need in no case so dwindle in their bodily capacity as to be forced to belong more to the house than fit to compete with their male companions out of doors, which we see is so much the tendency.

Women lead healthy, active lives, i.e., the lives of the ordinary out-of-door men labourers, such as is happily still the case in some country districts, and especially the case in the colliery districts of South Wales, where they are mostly fine strong-bodied individuals, and many of them are far more powerful than the average man. Their condition is entirely due to the fact that they work with pick and shovel, like men do, and do so properly clothed in jodhpurs.

The choice of clothing here is, of course, the choice of necessity, otherwise the more universal pattern is different from theirs, and consequently the wants of a vigorous constitution.

OPTHALMIA NEONATORUM: ITS ETIOLOGY AND PREVENTION.

By SYDNEY STEPHENSON, M.B., C.M., Ophthalmic Surgeon to Queen Charlotte's Hospital, &c.

(Concluded from page 350.)

It is, however, probable that there is another means whereby the eye becomes infected in utero, namely, by the passage of gonococci through the intact membranes. The first authentic case of this kind known to me was reported in 1878 by Rivar, of Lyons, and since then cases have been published by Chacon, Strzeminski, and Armaignac. Armaignac's case (Annales d'Oculistique, October, 1803) was so well reported as to deserve a word of passing description. An ill-developed infant, weighing only 1,286 grammes, was born at the eighth month, after a labour lasting one hour and a half. The membranes were ruptured by the midwife three-quarters of an hour before the expulsion of the foetus. At birth the eyelids were found to be red and swollen, and, on separating them, pus escaped from the eyes. A purulent viritis was also present. The mother had borne one child two and a half years before, and that child had remained free from ophthalmia. During her second pregnancy, however, the mother had suffered from metritis. One must therefore admit that so-called congenital ophthalmia neonatorum "does occur, although very rarely. Nieden's case (Klin. Monatbl. f. Augenheilk., October, 1851), where a baby, born in a caud, developed ophthalmia twenty-four hours later, doubtless belongs to this class. Under the above circumstances, we must, for the sake of completeness, assume the existence of a congenital metritis, with the passage (direct or indirect) of gonococci into the amniotic fluid, although that is a possibility upon which it would be most interesting to hear the expert views of members of the Society. Finally, Dr. Mules ('Essay on Ophthalmia Neonatorum," 1888) has claimed that during the passage of the foetal head through the external orifice, specific muco-pus may be introduced directly into the eyes by a mechanical action of the tightly-stretched edge of the perineum. This interesting fact, which Mules has himself seen, need not detain us, inasmuch as for present purposes such cases may well be classed with those where infection occurs shortly after birth.

The recognition of the connection between leucorrhoea in the mother and ophthalmia in the baby certainly dates back to 1750, when Quellmats (Cenntubl. f. Augenheilkunde, February, 1804) insisted upon the point. The fact was mentioned by Goetz in 1791, and by Selle in 1793. It is, however, gratifying to note that to an Englishman, Dr. Benjamin Gibson, of Manchester, who wrote in 1807 (Edinburgh Medical and Surgical Journal) that "in 1591 we owe the first clearly reasoned description of the rational means of preventing ophthalmia neonatorum. I cannot refrain from quoting the exact words, which are as follows:

(c) Read at the meeting of the Obstetrical Society of London, July 1st, 1808.
"(1) To remove, if possible, the disease in the mother during pregnancy; (2) if that cannot be accomplished, to remove artificially as near to the term as possible, from the vagina at the time of delivery; and (3) to pay, at all events, particular attention to the eyes of the child by washing them immediately after delivery with liquid calculated to remove the offending secretions and prevent its inoculation."

A few years after the appearance of this article, Dr. John Vetch ("Practical Treatise on the Diseases of the Eye," 1820, p. 242) furnished the experimental proof of the truth of Gibson's description by inoculating the eyes, without ocular antiptic, and thereby inducing gonorrhea within thirty-six hours.

To Créde, however, undoubtedly attaches the credit of having devised the most practical means of preventing ophthalmia neonatorum. This was by the application of a single drop of a 2 per cent. solution of silver nitrate simply dropped into the baby's eyes as soon as possible after birth. Writing in the year 1881, Créde explains that during some seven years before the adoption of his plan, no less than 10 per cent., in round numbers, of the 2,266 babies born in the Leipsic Maternity Hospital developed ophthalmia. After the systematic use of the silver nitrate, the infants born with the infection, among 1,600, was attacked, that is, 0 per cent.

As Dr. J. Watt Black, a former President of the Society, has justly said, when discussing this question a few years ago: "Except the introduction of vaccination for smallpox, certainly, at my suggestion, is the prevention of blindness in children" ("Transactions," Vol. xxv., 1894)—a sentiment with which I am in complete accord.

Many attempts have been made to replace silver nitrate by other agents, antiseptic and otherwise. This includes carbolic acid, sublimates, sterile water, iodine solution, protargol, anidol, iodine trichloride, to name only a few of the number. Each and all of the foregoing agents, with the possible exception of carbolic acid and protargol, have proved inferior to the 2 per cent. silver recommended by Créde. A glance at the following figures, modified from Köstlin's tables by Dr. Lucien Howe (American Journal of Ophthalmology, Vol. iv., 1897, p. 232) and myself, will render this obvious:

**Agent.**

1. Silver nitrate, 1%... 1.223 2.42
2. Carbolic acid solutions... 1.62 0.77
3. Sublimates, 1%... 2.061 0.47
4. Sterile water... 5.83 3.12
5. Carbolic acid solutions... 731 0.12
6. Protargol, 20%... 2.100 0.28
7. Anidol, 1 in 4,000... 260 0.74

Although objections have been raised to anything like a general adoption of Créde's method, yet these objections have been of so nature as to render it impossible to examine the seriously, let alone to refute them. On the other hand, of 1,100 medical men who replied to a circular letter on ophthalmia neonatorum issued by Professor Hermann Cohn, of Breslau, in 1896, fifteen only were opposed to the general introduction of the Créde method ("Ueber Verbreitung u. Verhütung der Augenerkrankungen der Neugeborenen," Berlin, 1896). Of the dissentients, one alone (Dr. Wilbrand, of Hamburg) was able to bring forward any definite objection in the shape of consecutive corneal opacities. Two or three other objections have been mentioned by various writers. They are three in number, viz., (1) conjunctival catarrh, (2) conjunctival hemorrhage, and (3) corneal opacities or ulcerations. It will not be a waste of time to examine these points one by one.

(1) That the use of 2 per cent. solution of silver nitrate is often, perhaps always, followed by a discharge from the eyes, and in rarer instances by a certain amount of hyperemia which will be described more particularly below. This has had practical experience of the method. Cramer's observations (Centrallbl. f. Gynäkologie, 1899) bear out this statement. He found an appreciable reaction in no less than 96 per cent. of his 100 cases. This, he thinks, is closely connected with the development of the baby, and to some extent with the mode of birth. Cramer believes that in a large number of instances the silver sets up inflammation of the conjunctiva, and entails incurable sequelae. It must, however, be pointed out that Cramer did not adhere strictly to Créde's method, but in order to secure a full distribution of the solution, opened and closed the baby's eyes with his finger and thumb a number of times. This makes it possible that traumatism had something to do with his bad results.

In order to ascertain the facts, Drs. Brehaut and Worthington, of Queen Charlotte's Hospital, have made a number of observations upon babies in whom Créde's method had been employed shortly after birth. The results were as follows:—Between January 5th and January 21st, 1903, fifty consecutive babies were closely observed, and in all, except possibly one, there was some reaction after the use of the silver drops. This took the form of a watery, mucous discharge from the eyes, unaccompanied by any appreciable redness of the ocular or palpebral conjunctiva. In a few instances a small discharge from the eye was noted within one hour of the application, but usually it was not observed until three hours had elapsed. It persisted from four hours to two and a half days.

Zwiefel (Centralbl. f. Gynäkologie, 1900, Nr. 51) has lately conducted some suggestive experiments to ascertain the cause of the catarrh that so frequently follows Créde's method. In 816 newly-born babies that observer washed one eye with distilled water before applying the silver, while, after the silver had been applied, he irrigated the other eye with a dilute solution of sodium chloride. Zwiefel found that catarrh was much less common when sodium chloride was applied to the eye, and therefore thinks that catarrh may be due to the presence of the saline tears from the newly-born child, and, logically enough on this view, advises that the silver solution be employed after the tears, and afterwards neutralized by means of a solution of salt.

So far as I can gather, there is no evidence to show that the application of 2 per cent. silver can cause an actual inflammation of the conjunctiva. Post hoc is not always propter hoc. At most, it may predispose to such inflammation by reducing the resisting powers of the parts, so that common micro-organisms, usually non-pathogenic as regards the conjunctiva, may assume infective powers. This view is borne out by the undoubted fact that in many mild catarrhs of newly-born babies where the silver has been used nothing can be found in the conjunctival secretion beyond the S. p. albus and the ubiquitous Xerosis bacillus, which some authorities think to be normal, or almost normal, inhabitants of many healthy eyes.

(2) It is a rather curious coincidence that several cases have been personally observed by the writer of this article and the conjunctiva has followed the use of silver drops. For example, A. J. Abbe (Annals of Ophthalmology, 1899, p. 10) mentions such a case in a baby, born at term, but weighing only five pounds. Some twelve
hours after birth, owing to the existence of discharge from one eye, a drop of a 6 per cent. solution of silver nitrate was used, but "before this was done," to quote the author's words, "the lid of the right eye had begun to swell and to be red." Shortly after the application, blood commenced to trickle from one eye, and this was soon followed by bleeding from the other eye. Despite treatment, the baby succumbed about two days after the bleeding was first noticed. In De Schwan- n-feld's case (April 18th, 1891), a 2 per cent. and then three hours later, a 4 per cent. solution of silver nitrate was applied to the eyes. Twelve hours afterwards bleeding from the conjunctiva set in, and persisted for two days. The author, in regard to the cases mentioned it is clear that in neither can the haemorrhage be charged against Credé's method, in which a single drop of a 2 per cent. solution is used.

In a case recorded by Pomeroy (New York Medical Record, August 20th, 1897), Credé's method appears to have been adopted one day after birth, and was followed by a slow oozing of blood from the conjunctiva. Baby died. In this connection it may be noted that bleeding from the conjunctiva has been seen by several authors in babies suffering from, or convalescent from, ophthalmia neonatorum. Hanzell (Ophthalmic Record, February, 1901) described such a case, in a child born at the end of a month, and treated with silver nitrate. Netteship ("Diseases of the Eye," 1897) met with a similar condition. Oettinger ("Jahresbericht," 1900, p. 458) mentions the case of an undersized baby in which a superficial hemorrhage occurred from the conjunctiva of one eye, and was followed next day by hemorrhage from the skin. Death took place in six days, and the autopsy revealed hemorrhages into internal organs.

Indeed, it may fairly be asked whether there is any causal connection between the use of silver drops, on the one hand, and conjunctival bleeding on the other. In trying to decide this question we must remember that the children, newly-born with hemorhages, as witness those not altogether uncommon conditions epistaxis, cephalhematoma, sterno-mastoïd ecchymosis, meleona neonatorum, omphalorhagia, and visceral hemorrhages. In some babies, again, aside from any definite anatomical lesion, there is a great tendency to spontaneous bleeding. Although rare, this so-called "idiopathic hemorrhage" (which appears to be distinct from hemophilia) is well known to those who have much to do with very young children. It has been estimated that death occurs in from 30 per cent. to 60 per cent. of the cases, and the condition, in some cases, almost certainly congenital syphilis. Cases of this kind have been recorded where hemorhage occurred from the conjunctiva, apart from any use of silver drops. Thus Kusich ("Jahresbericht der Ophthalmik," 1898, p. 274) reported such a case in a baby one day old, which proved fatal in about seventeen (a) days. It is quite likely that Pomeroy's case (the only one in question) belonged in reality to that class.

It is alleged that corneal opacities may follow the use of the Credé method. Few of the recorded observations with regard to this point will bear any critical examination. Wilbrand's two cases have been mentioned in neither of which a profuse discharge was ascertained. But despite Professor Cohn's careful inquiries into the facts—a how the method was carried out, nor (b) the actual strength of the solution employed. I must leave you to judge whether or not that the conditions of this kind. Van den Bergh (Presse médicale belge, October 13th, 1895) reports a case where the energetic use of sublimate and of after 2 per cent. nitrate of silver was followed within twenty-four hours by opacities of one eye. But none of the cases has been recommended to a drastic measure of prophylaxis. Romié (La Stycie, February 2nd, 1896) quotes cases where a fibrinous conjunctivitis and corneal opacities followed the use of Credé's method, but his statements are open to a similar kind of criticism.

Against these inconclusive statements we may put the fact that amongst 30,000 babies treated by Credé's method by Dr. W. (Berl. klin. Woch., No. 33, 1892) an unfavourable reaction was never observed.

The same remark applies to the 24,723 babies tabulated by Dr. R. Köstlin. It may be taken for certain, as Dr. Lucien Howe has shown, that if a bad result could be traced to the Credé method, the fact would be accorded a wide publicity.

Two other objections have been raised to anything like the general adoption of the Credé method: (1) that it is too complicated to be recovered by the midwife; and (2) that it does not always prevent the development of ophthalmia.

(1) That the ordinary midwife is too unimportant to apply the method correctly can scarcely be admitted as a serious argument. She is often compelled, for instance, to undertake things that require at least as much intelligence as applying a drop of liquid to a baby's eyes, such as tying the cord, or giving a vaginal douche. Michaelson's case (Centralblatt f. prakt. Augenheilkunde, 1900, p. 63) where a midwife, having run out of the 2 per cent. solution, hastily sent to the nearest chemist, and obtained a solution of 20 per cent. silver, which she dropped in the eyes of two babies, with consequences that may be better imagined than described, must surely constitute a unique instance of carelessness on the part either of the chemist or the midwife. It is, however, no argument against Credé's method. Nevertheless, stress has been laid upon this objection by several of the contributors.

(2) Does Credé's method always prevent the development of ophthalmia neonatorum? The answer to this question must be in the negative. In response to Cohn's oft-quoted circular, replies were received from thirteen medical men, who had met with no fewer than 370 cases of blennorhea neonatorum in 3,500 births—i.e., that it is to say, in 12 per cent. This seems a startling result. But a moment's reflection will show us that the percentage ought to be calculated, not from the results of thirteen returns only, but from the whole number of replies to the circular. Then there remains the fundamental fact, namely, that amongst the 24,723 babies included in Köstlin's lists, where the Credé plan had been used, only 0.65 per cent. developed ophthalmia.

Indeed, it may be said that these silver drops should prevent ophthalmia when the eyes have not been inoculated with specific secretions either just before or just after birth. On the other hand, it may reasonably be anticipated that the secretion, which I admit to be rare, or secondary inoculation, which I know to be common. Hence the method may be expected to fail in a certain small percentage of cases, and that has been shown to be so by Köstlin's figures.

To sum up the whole matter, the sole disadvantage of the Credé method, according to my view, is the production of a more or less trivial catarrh of the conjunctiva, and, after all, what is that compared with the risks of being blinded by ophthalmia?

The Obstetrical Society of London acted well and wisely when it caused to be inserted in its midwives' syllabus the disclaiming of babies' eyes with a 1 in 4,000 solution of corrosive sublimate. The question now is whether with all the evidence before it the Society might not be induced to record a formal approval of Credé's method. I recommend it for general adoption. That recommendation, coming from such a body, would go far to strengthen the hands of those who for years have been trying to get the plan universally adopted. It would, moreover, have an immense influence in still further reducing the ravages of ophthalmia neonatorum.

The twenty-second annual dinner of the President's, Fellows and Honorary Fellows of the Royal College of Surgeons, Ireland, will take place on the morrow of St. Luke's Day—Monday, the 19th inst—at 7.30 o'clock, p.m., in the College Hall.
Vienna Clinical Lectures.

SPONTANEOUS FRACTURE OF A VESICAL CALCULUS,
By Prof. G. KAFSAMMA, M.D.,
Vienna University.

The spontaneous fracture of a vesical calculus is a phenomenon of sufficient rarity to justify such a case being placed on record. In my search through the literature of the subject I found but sixty such cases. The resource to litholapaxy in modern times has made the probability of such cases small, and the future even less frequent. In the observed cases were, almost without exception, urates. In one case, however, that of Benno Schmidt, the stone was a phosphatic one, and in the case of M. Simons it was an oxalate. Fully 90 per cent. of the cases occurred in old men, and the rest in 15 refused proportion between young women and children. In the first observed case, that of Borricinus (1671), the patient was a boy, et al. 7. The conditions under which the fractures occur are unknown, as Zuckerkandl, in his work, “Local Diseases of the Urinary Organs,” in 1809, does not mention them. The theories which have been put forward to explain the phenomenon are principally based on chemical grounds. Heller, in 1863, put forward the theory that between the layers of uric acid occur deposits of porous ammonium phosphate, which, owing to their porous nature, contain urine, which after a little undergoes decomposition, with the production of carbonic acid and the forming apart of the segments of the calculus. Southam (1868) also added to the development of general theory. Ulitzman, in accepting Heller’s theory, considered that chemical changes occurred in the calculus and also crystalline metamorphoses, brought about by alkalinity of urine, which had a solvent effect on the uric acid, causing its partial removal and replacement by porous forms of the alkaline earth. Ord, in 1881, considered that the chemical changes in the constituents of the urine were the principal cause. The calculus, saturated with urine to its nucleus, was affected by the chemical change in the secretion, and by chemical action the stone was forced asunder in fragments. On the other hand, Leroy d’Etiolles (1855) found in the description of the nucleus an explanation of the fracture. Frish finds the cause in the development of bacteria. We see that these theories are in opposition one with another. We have not sufficient data to establish an acceptable theory, and those put forward are not satisfactory; they rest on hypotheses unsupported by facts.

I now bring before you a case of spontaneous fracture of a vesical calculus, which, I think, cannot be explained by any of the aforesaid theories. A man, et al. 74, suffering from a great enlargement of the prostate gland; Dittel in 1893 performed on him the operation of litholapaxy. Two years afterwards, Schustier, finding that the growth of the prostate had so modified the urethral passages, he performed the passage of straight instruments, performed a perineal lithotomy and removed two calculi, each of which was the size of a walnut. Not long afterwards the symptoms of stone in the bladder returned. He suffered from spasmodic pains in the bladder, with violent desire to make water. When I was called to see the patient I found him in a truly lamentable condition; every ten minutes he strained violently to pass water, and suffered from severe spasms in the bladder; he was bathed in sweat, and cried out with the sharpness of the lancinating pains from which he suffered. I introduced an elbow catheter of silk, which, owing to the enlargement of the prostate lobe of the left side entered the bladder with difficulty. On entering the vesixus was impacted on a calculus. There was no urine in the bladder, with the exception of the calculus, empty. Under the influence of morphia, he obtained relief from his pains. On the second and the third day the attack was repeated, palliative treatment only being adopted, as he was suffering from an attack of bronchitis. Going to his advanced age, and being naturally inclined to keep him as a least as possible under chloroform, I decided not to perform the perineal lithotomy, but to do the high operation, which I did, extracting forty-nine calculi. I completely closed the wound; the patient made a good recovery, getting up on the seventh day. The calculi presented on their exterior a smooth surface, and elsewhere, there were irregular cleavage. The stones were wholly of uric acid, perfectly smooth and dense, no evidence of porosity being present nor trace of crack, nor presence of phosphates; they presented as beautiful stratifications as an agate, and layers of lines of urates. Of the forty-nine stones removed it was possible to form ten groups. All these ten had the same form, and were of the same size. The majority of them were triangular in form, and in weight they varied from 8.5 grammes to 12.5 grammes. Four of the calculi were formed of four fragments, four of them of five fragments, one of six fragments, and one of seven fragments. The fracture was clearly due to a mechanical conformance to some law, as appears from the compact line of cleavage. The fracture appears to be produced by the severe spasms of the bladder alone. Those who saw the patient during his paroxysms of pain prior to the operation will not hesitate to credit the bladder with a crushing power equal to the task of fracturing the calculus. This view is not new, in 1835, and Benno Schmidt, in 1865, held that the pressure of the bladder was sufficient. In 1869 Civiale gave it as his opinion that contraction of the bladder was sufficient to occasion the fracture. And although this theory was finally accepted and announced by his pupil, Debout d’Estrées, and acknowledged as possible by Severeano, in 1887, in the Congress in Moscow, it is not to be found, even as a curiosity, in the German literature. Civiale considered that such fractures were due to hypertrophy of the muscular coat of the vesixus; but there is no necessity of the existence of such, as my case demonstrates. When suturing the walls of the bladder, the patient I had to be very careful not to penetrate the mucous coat, as the walls were very thin. I know that this cause, violent contraction of the bladder, is not sufficient to account for all the cases. It is difficult to explain the fracture of a single stone from this cause, also in cases where, owing to prostatic hypertrophy, the insufficiency of the true bladder tissue, with residual urine, the essential condition, according to Ulitzman, for the formation of a calculus. In my case there was marked hypertrophy of the prostate with insufficiency of the bladder and residual urine. After the extraction of the calculi its cavity measured seventy cubic centimetres. On passing
a catheter prior to operation the bladder could be felt to grasp the instrument, and to press the calculi together. By the violent pressure of the calculi together they were cracked in lines of least resistance, and afterwards they broke from a repetition of the pressure. Similar observations have been made on pressure as a cause by the following surgeons:—Von Crosse, who removed twenty-two calculi, weighing two and a half ounces; one of these was broken a short time after its removal; the remainder, consisting of twenty-one calculi, were ununited; formed three stones; of these one consisted of four fragments, one of eight pieces, and one of nine pieces, all of which had been fractured at different times. Croft removed forty fragments, which formed three large calculi, from a man, æt. 74, in St. Thomas’ Hospital. In Walther’s Museum (No. 1,945) is found a calculus consisting of nine wedge-shaped pieces. In 1715 Walther removed twelve fragments which, reunited, formed one large calculus. Leroy d’Itiéolles observed the separation of one large calculus into four parts. The case placed by me on record shows, I think, very clearly the possibility of the fracture of a calculus by the contraction of the bladder alone.

THE TREATMENT OF CERTAIN INFLAMMATORY AFFECTIONS BY THE LOCAL APPLICATION OF ANTIPHLOGISTINE.

By COLIN CAMPBELL, M.R.C.S., &c., Southport.

My experience of antiphlogistine is not very extensive, but it has been varied, and, so far, quite satisfactory. As the experience has been expressed that I should make known my results, whatever they were, I willingly do so. The cases in which I have used it are as follows:—Pleurisy, two; chilblains, one; phlebitis, one; bubo, one; Gout arthritis, two; laryngeal ulceration, one.

1. Pleurisy.—Dr. B. was under my care last within an hour, and a temperature of 103°. His previous attacks had occurred at his home, where careful poulticing was practicable, but in apartments this was unsatisfactory, and so it occurred to me to try antiphlogistine.

The material was warmed and "trowelled" on for many inches around the pleuritic centre, then covered with non-absorbent lint and Jaconet. (I can only obtain this lint from Mr. Martindale, New Cavendish Street.)

The result was remarkable; the pain disappeared within an hour, and the high temperature within two days.

Many advantages over poulticing were noticed by the patient; facility of application, no unendurable heat, rapid relief of pain, its adhesiveness rendered movement possible without tight bandaging or the alternative sudden influx of cold air. The following was a case of a poultice from the skin when loosely applied.

I had no further opportunity of testing antiphlogistine in pleurisy until July, 1903, when a small patient, Miss B. D., æt. 5, who was at the time under treatment for traumatic pulmonary abscess, developed a sudden rise of temperature, with acute pain over the large cavity situated in the left base. Friction sounds were absent, but the other symptoms left no doubt as to the attack being inflammatory and pleuritic.

The result of the first application of antiphlogistine seemed marvellous—the pain disappeared in twenty minutes, although the temperature continued above normal for a week. Attacks of pleurisy do not always exist are serious, not alone in reducing the patient's strength, but also—by rendering coughing painful—cause the retention of sputum or pus, as the case may be.

2. Chilblains to many will appear a trilling disorder, but as one whose schooldays in winter were rendered miserable by them I can assert that they are most madmen's. Last winter, a daughter, æt. 11, suffered severely from them. Each time antiphlogistine was applied the redness and intolerable itching disappeared in a night. I have tried remedies innumerable with no such result.

3. Phlebitis.—The case occurred last March in a young woman, K. G., who was under treatment for asthma. She had suffered a slight abrasion over the inner aspect of her tibia, which, being neglected, had adhered to her stocking. Two or three days after the saphenous vein was found inflamed to the extent of about three inches. A copious dressing of antiphlogistine was applied, rested ordered, and a second dressing in six hours. In twenty-four hours the inflammation had subsided. Nature and zinc ointment completed the cure.

4. Bubo.—Last July a young gentleman asked me to see a swelling in his groin, stated to be connected with a previous operation for appendicitis. Examination revealed phimosis with lacerations of the adenoids. Last stone of the prepuce, and a very insanitary condition of these parts. Inflamed lymphatics led to the bubo, which was about the size of a small split lemon; no fluctuation could be found, but it was red, very tender, and looked decidedly as if it must suppurate. Large douchings were prescribed between plans and prophylactic and antiphlogistine, and the bubo, to be renewed every four hours. In two days, it began to subside. A fortnight later it was the size of half a walnut, and I allowed him to go on his holiday without fear of suppuration.

Of course, I do not attribute more than a part in the improvement to antiphlogistine, but efforts to maintain anything like an aseptic condition of the preputial sac were ineffectual owing to the existence of the tight phimosis, and under these circumstances I think the avoidance of suppuration was due to the dressing employed.

5. Gout Arthritis.—The patient had suffered from his first prolonged attack in the summer of 1902, and attributed it to recent indulgences in strong tea, sparkling water, and strong gin. Local applications then gave practically no relief. The second attack occurred in April, 1903, when, after a week of the usual local treatment (with medicines, of course), antiphlogistine was tried, with immediate relief.

The result in the third attack, July, 1903, is unique. The writer had had a wide experience in the treatment of gout in others, but now he is the patient. The attack commenced acutely in the great toe in the early morning. Antiphlogistine
was applied at 7 a.m., and every four hours during the day. By the next morning at 7 he was able to resume his leather boot.

Quite recently I have been called to see a patient suffering from laryngeal tuberculosis. Exposure to the rays of radium bromide appear to lessen in a remarkable way the sensitiveness of the ulcers to which they can be applied, but he still suffers much, and recently, after a chill, developed symptoms of that terrible, fatal effusion. When this does occur, although there is no track, I have no procedure. I have ever known to delay the inevitable end—is the immediate blister produced by brown paper soaked in dil. ammon. fort. But his symptoms rarely demanded this, and as poulticing the throat is, of all places, most impracticable and useless—every movement loosens it—I applied antiphlogistine. All I can say is that the dreaded "effusion" did not proceed, it appeared to have been checked by the treatment.

In conclusion, I would express a tentative opinion that antiphlogistine exercises a decided effect in abstracting or diverting excessive blood supply from an inflamed part, and I submit that the foregoing cases justify this opinion.

THE RELATION OF DENTAL HYGIENE TO THE GENERAL HOSPITAL.

By William Hern, M.R.C.S., Dental Surgeon, Middlesex Hospital.

The lecturer dwelt on the value of medicine as a calling, in that it developed the highest faculties of man and afforded the widest scope for the exercise of courage, perseverance, tact, and human kindness. He referred also to the enhanced facilities now offered by the well-equipped laboratories and class rooms lately opened at the Hospital Medical School for the acquisition of scientific professional knowledge.

He pointed out that one of the great differences between the medical methods of past and present times was the substitution for the old empiricism treatment based upon an inquiry into the causes of disease. Modern practice must resort to the farmer, who knew, and bestimes destroyed, the sources of blight and blight. From the utilitarian point of view the labours of the patient investigator into the causes of disease far outweighed in value the devotion and self-sacrifice of the unscientific philanthropist and guardian of the sick. The popular tendency was to ignore the causes of ill-health. Had the doctor, in "Macbeth," complied with the king's request to find the disease of the Commonwealth, he must have pointed to the unsuspecting king himself. Martyrs to the results of evil habits and the thralls of dental disease seemed to regard their troubles as the thorns that made inevitably springing into being with the rose of life, the possession in the possession of remedies for a complaint must not blind them to the necessity of doing all they could to render that complaint impossible. To this end the medical man required to impress upon the people the strict observance in everyday life of hygienic principles. Thus alone might the doctor's visits be rendered far and few between. A sick man's recital of his woes had usually reference to his symptoms only; the medical man's duty was to discover and treat the underlying cause.

Oral sepsis, that is, a foul and infectious condition of the mouth cavity, and dental caries or decay, he remarked, were affections of the same class; it was most important to ascertain the origin. The mouth, being open to the air, moist and warm, and having distributed in it from time to time the "dbris of food" itself the habitat of minute organisms, served as a most prolific and efficient chamber and breeding-house for rapidly-multiplying disease germs. Experiments in the steps of Leuwenhoek, Gallipe, Miller, and others had been able to demonstrate that though some of the micro-organisms of the mouth were harmless to man, others might occur therein which had been identified as associated with maladies the most deadly to humanity. The effect of the mischief-working germs on the gums was to produce inflammation therein which might lead to loss of teeth, inflammation, to general but minor disturbances of health, or to acute and fatal blood-poisoning. That the worst possible results did not commonly follow on prolonged oral sepsis was because probably the patient by degrees became to some extent immune to his own poison.

Dental caries, or decay, of the teeth, he said, was a disease of all ages of the world's history, and most rife among civilized peoples. Nearly 80 per cent. of the children in industrial schools were found, in an investigation by the British Dental Association not long ago, to be subjects of it. Of some half-dozen theories advanced to account for dental caries those which might be termed the chemico-parasitic, attributing the affection to the work of disease germs, was the one now regarded as tenable. The predisposing causes of caries—those which might be said to prepare the soil for the parasitic growths—included abnormalities in the form, structure, and position of the teeth, debilitating illnesses, congenital tendencies, certain occupations, the somewhat obscure influences coming under the head of "civilization," and last and mainly the diet, more especially one consisting largely of vegetable matter, and, it might be added, milk. But that which constituted the primary or exciting causes of caries was the food and situations of the various parts of the teeth, whether such as would retain decomposing and therefore infectious food dbris, or such as being rounded or continually swept by the tongue and lips did not admit of the lodgement of particles. It followed from this that though the teeth of a robust man did not suffer in the same degree, they showed caries in the same positions as in the teeth of the sickliest and most weakly of mortals.

Experiments with sound natural teeth, placed in various mixtures, had evolved the following facts:—Alburninous and fatty matters mixed with saliva and kept warm produced by decomposition an alkaline reaction. Fermentation occurred; the acid yielded an acid solution which, like a weak solution of lactic acid, effected the first stages of caries; the second stage was accomplished by the solvent action of micro-organisms provided by the saliva. For the prevention of caries, therefore, the important considerations were, first and foremost, regular and systematic sweeping of the teeth with toothbrushes stiff enough thoroughly to clear away food remnants, and secondly, the use of antiseptic mouth washes. That these measures and the consequence of their neglect had not been brought before the lower orders of society, their children especially, was a reproach to preventive medicine, if not to the State. Thousands of our working classes yearly sought the hospitals because of ailments directly or indirectly due to unclean mouths, caries, or loss of teeth. A State which could afford to control the drunken, provide the poorest with free instruction, and appoint opthalmic surgeons to Board Schools must surely be able to organize some system of gratuitous dental supervision and treatment to supplement the necessarily limited work of our few existing dental hospitals. If it should be impossible to establish State-aided dental dispensaries, there might at least be provision for instructing the children of the poor in oral hygiene. The cause no less than the effects of oral caries or sepsis can be controlled within the purview of the medical profession as a whole. He urged that a knowledge of the importance of good teeth to the well-being of the body, and instruction how best to preserve them, should be imparted to all patients,
especially the poor and ignorant; and the nurse who attended to the ablation of the body should see even more punctiliously to the cleansing of the teeth.

Acquaintance with dental pathology, he added, afforded a clue to the physician, the surgeon, and the throat, ear, and the eye specialist in tracing the origin of maladies of the most diverse kinds; and he who by timely warning and advice sought to save his patients from the evil consequences of oral sepsis and dental caries was choosing the better part of medicine—the prevention of disease, which was better than the most brilliant cure.

THE ATTITUDE OF THE PRACTITIONER.

By SIR CHARLES WYNHAM.

Addressing the students of the Charing Cross Hospital at the close of the prize distribution, Sir Charles said he stood before them as one who formerly had the honour to belong to the profession they were about to enter. His diploma was in order, and it was competent for him to operate upon or prescribe for any one of them who might have the pluck to entrust himself to his tender mercies. A little learning, however, was a dangerous thing; the sciences of therapeutics of those days had long since been forgotten, and the theatres in which his operations were now conducted were not of a surgical character. Theoretically, he belonged to the same direction that stood apart, but not for him. The memory of that part in his life which was now the present, and would be the future in theirs, was to him a bond between them that the rapid and ruthless passage of years could never wholly efface. His first counsel to them was to put before and above everything else the primary virtue of loyalty to their profession. They could not have too exalted a conception of the vast importance, the nobility—he would almost say the sanctity—of their calling. Science demanded moral courage from its votaries. In this age, when the smaller vices were multiplying, and with their attendant nemesis of disease, they must have the courage to call things by their proper names. If ignorance and misfortune conspired to drown it in misery by drink, drugs, or vicious life, he should be told so in the plainest terms. Let them not disguise the truth by some euphemistic Greek phrases ending in "itis"—phrases which fell weakly on one coward's ears and issued lightly from another coward's lips. To gloss over the vice which caused, nay was, the disease, and thereby encourage its continuance, was high treason to their profession. There were occasions when an agreeable bedside manner was less appropriate than a dash of the caustic, staid honesty of an Abernethy. No less exacting were the demands made by their vocation upon the intellectual side of their nature. Never was there a time in the history of the healing art where greater alertness and versatility of mind were required by its practitioners. Increasing variety of disease demanded at their hands increasing resourcefulness. Never had their profession stood higher in man's estimation than now. They had, on the one hand, the most practical Sovereign of the day, King Edward, faithfully interpreting to them the sentiment of his subjects, and, on the other hand, the voice of the nation to sustain them. And there were still many unsolved problems to stir their ardour. For many as were the mysteries which the healing art had fathomed, they were as nothing beside that vast, but often obscure, universe of diseases which still ceaselessly throbbed and tossed on the rocky bed of pain and moaned around them with its many voices.

THE RELATIONSHIP OF THE MILITARY MEDICAL SERVICE TO THE CIVIL PROFESSION. (a)

By V. W. LOW, M.D.

Our medical unpreparedness before the Crimean war, and also in 1899, was not, observed the lecturer, the fault of any department. It was the fault of the nation. Economy was the motive; and, naturally, the humanitarian department of the Army must feel it, and most acutely. It was believed that anything but the trained fighting man could be purchased in the open market on the day. Practically this was done. If the breakdown of the medical arrangements was not absolute, this escape from utter disaster was due to the superhuman exertions of the R.A.M.C. officers and men, and to the Anglo-Saxon adaptability of the host of civilian doctors, nurses, and orderlies who were sent out. The war, however, brought medical civilians into closer contact with their military colleagues, who were, normally, far too much cut off from association with the general body of the profession. Quite lately, however, the status and pay of the R.A.M.C. officer had been improved so far that even promotion to be granted; and, more important still, officers in the early stages of their career might be "seconded" to hold posts in civil hospitals. It was to advances in this direction that the lecturer turned when he spoke in the Army Medical Service, and it would be by these means that the civil and military branches of their profession would be brought into closer union. Unlike any other branch of the Army, the medical department possessed a reserve for war of men perfectly trained for their profession, and untrained only in the administrative work which must fall to the lot of every medical officer with an army. "Improvisation" was the main feature of the Crimean war, and the medical service was the main obstacle to perfect success in the "mobilisation" of the medical reserve. He suggested that any scheme of medical organisation for military purposes must rest upon the R.A.M.C. and its framework. "Medical units" organised and administered by civilians were not economical, and not perfectly effective. Secondly, every civilian auxiliary officer entering his term of service should have a rank equivalent to that of his military colleagues of similar professional standing. Thirdly, the liability for military service should not be imposed upon the young civilian "reservist" for longer than one year at a time. Fourthly, there must be a reserve of the civilian auxiliaries. In the late war there were only two grades—consultants and civil surgeons. Three grades suggested themselves—Class A might consist of men recently (i.e., within three or four years) qualified; 300 or 400 would be needed for three army corps. Class B would be members of the junior honorary staff of Metropolitan and provincial hospitals. The trained physician was especially needed. The operating surgeon was required to assist and supplement the limited number of such surgeons already to be found in the R.A.M.C. Class C would consist of a few of the heads of the profession, including at least one eminent pathologist. Their natural field of work would be the large base hospitals, and they would also be general advisers. As to details, he suggested that members of Class A should receive a small retaining fee while on the yearly register; that they should, if possible, undergo a month's training in the field, for which period they should receive £1 per day; that, in the event of mobilisation, each man should be attached to a unit in a certain army corps, with the rank and temporary rank of a lieutenant R.A.M.C. In the event of re-enlisting for a third period of service they should receive, on mobilisation, the rank and pay of a captain R.A.M.C. Men of Class B had fixed responsibilities from which they were not easily dispensable. (a) Abstract of Introductory Address delivered at St. Mary's Hospital, on October 1st, 1903.
In their case the period of training should be made optional. A small retaining fee would be required, and about fifteen men would be needed for three in the corps. On mobilisation each should be attached to a definite unit with the temporary rank of major R.A.M.C. Three periods of enlistment, with training, would qualify for the position of lieutenant-colonel R.A.M.C. on mobilisation. Class C would consist of very few men, and to be chosen for it would be no small honour. In war time each man would receive the rank and pay of a surgeon-general. For the Militia and Volunteers some analogous system would be applicable.

REVERENCE AND HOPEFULNESS IN MEDICINE, (a)

By Sir SYDNEY DUCKWORTH, M.D., F.R.C.P.

In regard to the former, he remarked that a habit of reverence was everywhere becoming, but he ventured to think that it was less manifested in these days than formerly the case. The absence of reverence might be safely regarded as a symptom of decadence in manners. The spread of democracy and an extension of education need not necessarily entail bad manners, but has a tendency to bring the better ones of the past, but those who had reached his time of life would testify to a somewhat prevalent spirit of irreverence, and a tendency to a laxity of manners and conduct, which was certainly less marked in our earlier years. Such conduct, if not immoral, was at least significant of bad breeding. Passing on to his second point, that of hopefulness in medicine, he said the present period in the lives of most of his hearers was truly one in which hope was no longer a prominent feature, one in which little or nothing appeared to blight or darken it. If they were not inspired by hope now they never would be. Let them cherish that gift now and always. Speaking next of boldness as a necessary equipment of all who practised the physician's art, he said there were, and always had been, optimists and pessimists in medicine. While nothing was more damaging to a man's reputation than an unfounded evil prognostic, it faded badly with him who, not having recognised indications of danger, had consequently raised false hopes; yet there was a measure of hopefulness which was always becoming in the physician's duties, which was potent to inspire and to secure the highest efficiency, all engaged in the service of the sick. Such hopefulness should be carried to the bedside of the patient, and its power was not small, both in reinforcing remedial agents and in promoting recovery. With it lay much of the personal influence exercised by those who succeeded well in practice, and the absence of it sometimes explained the failure of others, often able and accomplished, to impress or inspire their patients. In thus urging a rational and wholesome degree of hopefulness in professional conduct, he was not for a moment approaching the subject of that pestilent nonsense called "faith-healing," which in these days of widely-spread religious feeling was captivating many members of the body. It was truly deplorable to find that the sacred name of Christian was claimed for this method by persons whose education ought to be a safeguard against such posthumous folly. Perhaps the explanation might be found in the sagacious remark of John Hunter, that "everything new carries a greater weight and makes a deeper impression on a weak mind." They would do better to take to heart the words of Peter Mere Latham: — "Medicine, as it begins to touch upon higher interests, even the interests of life and death, should feel itself in alliance with higher motives than any which can be thought to help and quicken its pursuits as a mere science. Medicine claims a sort of general control over the handling; it calls upon the conscience as well as the intellect for more caution to avoid error, and more fearfulness of overlooking the truth."

BRITISH SANATORIA FOR CONSUMPTION.—XIV.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

ALTADORE SANATORIUM, IRELAND.

Altadore Sanatorium occupies a remarkably fine situation on the slopes of the Wicklow Mountains and in the midst of a district peculiarly rich in attractive features. It has been adapted from an old country mansion with picturesque turrets at the four corners, and admirably serves its present purpose as a sanatorium at an elevation of 750 feet and is effectively protected on the north, east, and west by woods and mountains, the latter rising to a height of 2,000 feet. Delightful views of the sea five miles distant towards the south are obtained from the house and grounds. The various rooms are large and airy, and have been so modified as to allow of a satisfactory conduct of open-air methods. The dining-room is well fitted for its purpose, and from it are a peculiarly attractive views of woodland, vale and sea can be enjoyed.

The extensive grounds of 630 acres present many special features. They are excellently wooded and particularly well adapted for the carrying on of carefully graduated exercise. Within the demesne is a charming glen with trout stream, several water falls, numerous plantations, lawns and conveniently arranged paths. For patients able to take advantage of the district offers opportunities for numerous fine walks, and the immediate neighbourhood is particularly rich in features of much interest. Convalescent patients can readily reach Powerscourt, the Dargie, Glendalough, the Glen of the Downs and many other spots of much beauty in which the district abounds.

Great pains are taken to make the life of the patients bright and cheerful. The wide expanse of view from the south windows of the building is expected to exercise a psychological influence rich in benefit for a restoration of physical vigour.

In addition to the numerous very suitable rooms in the house proper, there are a series of well-designed and very conveniently arranged bungalows. We enjoyed the privilege of sleeping in one of these during an exceedingly wet night, and found it everything that could be desired. The sleeping bungalows have been erected in a sheltered portion of the grounds near to the central building. They are provided with verandahs which well protect from driving rain. The bungalows face south and have been so constructed as to ensure for the patient the greatest possible exposure to fresh air while at the same time securing physical comfort.

There are also shelters in the grounds where patients may rest or engage in light forms of manual work or simple amusements. Carriages may be obtained at a reasonable charge by patients desirous of taking drives, subject, of course, to medical permission. A laundry is attached to the sanatorium.

The proprietor and resident physician, Dr. J. C. Smyth, has spent a considerable time at Nordrach, studying the hygienic methods of Dr. Walther, and treatment is carried out in strict accordance with the modern principles of open-air life. The doctor and his wife share the life of the patients, and constant medical supervision is exercised over the details of the daily routine of each. We were much struck by the wise combination of a rigorous rational régime with much of the amenities and enjoyments of home life. Such care is taken to provide a suitable dietary. The cooking is excellent.

The natural features of the place are exceptionally good. The soil is of gravel and sand, the rainfall comparatively small, the climate mild, and altogether the climatic conditions appear to be well adapted for the consumptive.

The building is such as will readily allow of considerable extension, and the grounds are so extensive and suitable for patients that the greatest privacy and quietude can be secured without leaving the estate.

—(c) Abstract of Introductory Address delivered on October 16th, 1903, at Liverpool University College.
GERMANY.

Oct. 7, 1903.

WATER POWER CAN READILY BE OBTAINED AND SHOULD PROVE MUCH SERVICE IN PROVIDING FOR ELECTRIC LIGHTING. THE SANITARY ARRANGEMENTS ARE GOOD AND AN EXCELLENT SUPPLY OF PURE WATER IS PROVIDED. PATIENTS SUFFICIENTLY STRONG CAN, IF WANTED DESIRABLE, ENJOY OUTDOOR SWIMMING IN A SMALL LAKE IN THE GROUNDS. CROQUET IS ALLOWED AND CAN BE PLAYED ON A GOOD LAWN CLOSE TO THE HOUSE.

ALTADORE SANATORIUM IS FIVE MILES FROM GREYSTONES, AND EIGHT MILES FROM BRAY, WHICH PLACES CAN BE READILY REACHED FROM DUBLIN (WESTLAND ROW OR HARcourt STREET STATIONS). CARRIAGES ARE SENT TO MEET THE TRAINS. ENGLISH PATIENTS WILL DO WELL TO TRAVEL BY HOLOHEAD. THE PASSAGE FROM HOLOHEAD TO DUBLIN OCCUPIES LESS THAN THREE HOURS, AND THERE IS A GOOD SERVICE OF TRAINS FROM DUBLIN TO BRAY AND GREYSTONES (DUBLIN, WICKLOW, AND WEXFORD RAILWAY). THE TERMS ARE FROM THREE AND A HALF TO FIVE GUINEAS, ACCORDING TO ROOM. THE ONLY EXTRAS ARE PERSONAL LAUNDRY AND ALCOHOLIC DRINKS, WHICH, HOWEVER, CAN ONLY BE TAKEN BY PERMISSION OF THE DOCTOR. FRIENDS AND RELATIONS ACCOMPANYING PATIENTS ARE ONLY ALLOWED TO STAY BY SPECIAL ARRANGEMENTS.

THE POSTAL ADDRESS IS ALTADORE, KILPEDDER, CO. WICKLOW; THE TELEGRAPHIC ADDRESS, "ALTADORE, NEWTOWNMOUNTKENNEDY."

FRANCE.

FROM OUR OWN CORRESPONDENT.

PARIS, OCTOBER 4TH, 1903.

FURUNCULOSIS.

PROFESSOR BROCO RECOMMENDS THE FOLLOWING TREATMENT FOR THIS TROUBLESOME AFFECTION. THE OLD HABIT OF PURGING THE PATIENTS IS GOOD, AND SHOULD BE FOLLOWED. A GLASS OF SOME PURGATIVE MINERAL WATER SHOULD BE GIVEN FOR THREE OR FOUR DAYS, AND THEN FRESH BEER YESTERDAY IS ORDERED BEFORE EACH MEAL IN A GLASS OF WATER, AND CONTINUED EIGHT DAYS. THE DIET MUST EXCLUDE WINE, ALCOHOL, POKE, &c., AND IF THE DIGESTIVE TRACT IS IN GOOD CONDITION, COD LIVER OIL, ARSENIC, OR IRON MAY BE GIVEN.

AN EFFORT MAY BE MADE TO ARREST THE DEVELOPMENT OF THE BOIL BY APPLYING TINCTURE OF IODINE OR LIQ. MOISTENED WITH SPIRITS OF CAMPHOR, OR A MIXTURE OF BOTH OF THESE IN EQUAL PARTS. M. GALLOIS, HOWEVER, RECOMMENDS—

IODINE, 3f. ACETONE, 5i.

EACH OF THE INFAMED BOILS IS TOUCHED SLIGHTLY WITH THE MIXTURE, AND IN GENERAL THE FOLLOWING DAY IT HAS DRIED UP. THE REMEDY SHOULD BE HANDLED WITH PRUDENCE ON ACCOUNT OF ITS CAUSTIC ACTION.

IF THE BOIL CONTINUES TO ADVANCE POULICHE WITH POTATO FLOUR OR STARCH MOISTENED WITH SPIRITS OF CAMPHOR. TO PREVENT INOCULATIONS OF THE REGION THE PARTS SHOULD BE FREQUENTLY WASHED WITH AN ANTISEPTIC LOTION (SUBLIMATE) AND COATED WITH BORIC ACID OINTMENT.

MYDRITICS AND MYOTICS.

M. J. TISSOT, IN PRESENTING SOME REMARKS ON THE INDICATIONS AND MODES OF ADMINISTRATION OF MYDRITICS AND MYOTICS IN OCULAR AFFECATIONS, SAYS THAT THE INDICTION OF ANY SOLUTION INTO THE EYE PRODUCES, ALTHOUGH CONSECRATIONS MAY BE USED, A CERTAIN AMOUNT OF PAIN. THIS INCONVENIENCE MAY BE OBLIVIED BY RECOMMENDING THE PATIENT TO LOOK UP AND BY LOWERING THE UNDER LID SO THAT THE DROPS FALL AT FIRST INTO THE CONJUNCTIVAL SAC. HOWEVER, AS THERE MIGHT BE DANGER OF THE SOLUTION PASSING THROUGH THE LACHRYMAL DUCTS, AND THUS BEING SWALLOWED BY THE PATIENT, THE FINGER SHOULD BE PRESENTED ON THIS PART AT THE MONTAGE OF THE OPERATION.

THE MYDRITICS MOST COMMONLY USED ARE ATROPINE, HOMATOMINE, DIOBOSINE, HYOSCYAMINE, HYOSCIN. ATROPINE IS THE BEST OF ALL. ITS INDICATIONS ARE: KERATITIS (HYPERCHRONIC) OR IMPETIGO OF THE CORNEA; HERPES OF THE CORNEA (SHOULD BE CONTINUED A LONG TIME); INTERSTITIAL KERATITIS. THE ATROPINE RELIEVES THE PAIN, AND

BY DILATING THE PUPIL PREVENTS THE FORMATION OF SYNCHI. IT IS IN AFFECTIONS OF THE IRIS THAT MYDRITICS ARE ESPECIALLY USEFUL. IF THE EYE IS TOO SENSITIVE TO THE ORDINARY SOLUTION (ATROPINE 1 GR., WATER 30IS.), THE FOLLOWING SOLUTION IN WARM COMPRESSIONS ON THE EYES SERVES EQUALLY AS WELL:

ATROPINE, GR. 6;
WATER, 3I.

A TEASPOONFUL IN A BOWL OF HOT WATER AND APPLIED TO THE EYE.

OR THE FORMULA OF GALEZOWSKI:—

| EXTRACT OF BELLODANNA, |
| EXTRACT OF HYOSCYAMUS, |
| WATER, 5X. |

MYDRITICS HAVE ONLY ONE COUNTER-INDICATION, WELL KNOWN TO ALL. AS THEY RAISE THE OCULAR TENSION THEY SHOULD BE ABSOLUTELY PROHIBITED IN GLAUCOMA.

MYOTICS COMprise SERINE AND PILOCARPINE. A FEW DROPS OF A SOLUTION OF SERINE SOMETIMES PRODUCES SHARP PAIN, BUT THE MIOSES IS PROGRESSIVE AND DURABLE. A LOWERING OF THE TENSION AND A DECREASE IN THE SECREATION OF THE CONJUNCTIVA ARE THE EFFECTS OF SERINE. PILOCARPINE IS LESS PAINFUL, BUT ALSO LESS TRUSTWORTHY.

M. DARIER PROPOSES THE FOLLOWING FORMULA:—

HYDROCHLORATE OF PILOCARPINE, GR. 1;
SULPHATE OF SERINE, GR. 1/2;
WATERY EXTRACT OF SURRENAL CAPSULES (EQL. PARTS), 5ISS.

WATER.

THE CHIEF INDICATION FOR SERINE OR PILOCARPINE IN GLAUCOMA, PRESCRIBED EITHER BEFORE OR AFTER AN OPERATION. FREQUENTLY IT OBVIATES THE Necessity FOR AN OPERATION, BUT EVEN AFTER IT IS USEFUL IN PREVENTING RELAPSES SO FREQUENT IN THAT AFFECTION.

GERMANY.

FROM OUR OWN CORRESPONDENT.

BERLIN, OCTOBER 3RD, 1903.

AT THE SURGICAL CONGRESS DR. KUIMMEL, HAMBURG, READ A PAPER ON RECENT METHODS OF EXAMINATION AND OPERATION RESULTS IN KIDNEY DISEASE.

HE SAID THAT THE NEWER METHODS OF EXAMINATION IN KIDNEY DISEASE WERE NOT YET RECOGNISED AS THEY CERTAINLY OUGHT TO BE. MODERN RENAL SURGERY HAD THROUGH THEM ENTERED UPON A NEW STAGE. THE METHODS WERE (1) RÖNTGEN ILLUMINATION IN CALCULUS DISEASE. A NEGATIVE APPEARANCE WAS HITHERO NO PROOF THAT NO STONE EXISTED AS THE PROCEDURE LEFT ONE IN DOUBT IN VERY FEW PEOPLE. THE TECHNIQUE HAD, HOWEVER, NOW ADVANCED SO FAR THAT A STONE COULD ALWAYS BE BROUGHT ON TO THE PLATE, AND THE ABSENCE OF THIS PROVED TO A CERTAINTY THAT NO STONE WAS PRESENT. (2) CATHETERISATION OF THE URETER. THIS HAD RECEIVED BETTER RECOGNITION. IT HAD BEEN ADVANCED THAT INFECTION OF THE BLADDER WAS CAUSED BY IT; BUT IN MANY HUNDREDS OF CASES HE HAD NEVER SEEN IT HAPPEN. NATURALLY, THE RULES FOR ASEPSIS WERE TO BE STRICTLY FOLLOWED. BY CATHETERISATION WE COULD COLLECT THE URINE OF EACH KIDNEY SEPARATELY. THIS WAS OF SPECIAL IMPORTANCE FOR THE CYROSCOPY, TO BE DESCRIBED LATER. THE QUANTITY ALSO AND THE DIFFERENCE IN THE EXCRETION OF THE TWO KIDNEYS WAS DETERMINED BY IT. CATHETERISM WAS VERY IMPORTANT FOR THE EARLY DIAGNOSIS OF TUBERCULOSIS OF THE BLADDER OR KIDNEYS. BY THESE METHODS, WHEN THE SYMPTOMS WERE NOT DISTINCT, DISTURBANCES COULD BE RECOGNISED. A CERTAIN AMOUNT OF DEXTROSTERE AND EXPERIENCE WERE NECESSARY FOR CARRYING OUT THE PROCEDURE, AND INSTRUMENTS HAVE NOW BEEN PERFECTIONED SO THAT THE URINE OF EACH KIDNEY COULD BE COLLECTED SEPARATELY. ABSOLUTELY CERTAIN RESULTS WERE, HOWEVER, SCARCELY LIKELY TO BE OBTAINED, AS ABSOLUTE
shutting off of each half of the bladder had not been yet reached. (3) Functional renal diagnosis. The most important method was cryoscopy, the determination of the freezing-point of the blood and the urine. This gave a reliable datum. He had used cryoscopy in 550 cases, and it had never yet left him in the lurch; the results of the examination had been confirmed at the operation or the autopsy. In normal renal function (200 cases) the average freezing-point was 0.56 (slight deviations were of no special value); it fell in double kidney disease and in insufficiency (77 cases). The method was important in hypertrophy of the prostate, in determining whether disease of the kidneys was present. In one-sided kidney disease, when the function of one kidney was normal, there was only a slight sinking of the freezing-point (74 cases).

The limits of the freezing-point, where nephrectomy for renal disease should not be undertaken, was 0.6. Nephrectomy only is permitted when the other kidney cannot be properly sounded. If the sounding is successful and the cryoscopy shows that the other kidney can perform its functions and those of the diseased one, then the latter may be extirpated. When operation has been performed in defiance of it being forbidden, death has invariably followed. A lowering of the freezing-point is possible from loading of the blood with carbonic acid. The speaker had never seen it from large tumours. In acute febrile diseases, such as typhoid, the freezing-point was always normal. In malignant new growths of the stomach, intestines, &c., if the nutrition of the part was good the freezing-point was normal; if there was much cachexia it fell as low as 0.65. In tumours of the kidneys, in hydro- and pyo-nephrosis, it was generally normal if the other kidney was healthy. Derangement of the tissue changes was not decisive. In the time before cryoscopy he had had a mortality of 16.5 per cent. in 240 kidney operations; since the introduction of cryoscopy it had fallen to 7.8 per cent.

The limits of medical men especially interested in the study of spas and bathing resorts led many of their number to Bad Neuenahr and the Ahr Valley a few days ago. As the discovery of the Apollinaris Spring in 1852 resulted in the founding of a spa, later on, at Neuenahr, some 200 physicians from all parts responded on the present occasion to an invitation to view the celebrated Apollinaris Spring, the directors of which gave information concerning the various processes of cleaning, filling, and despachting the 30 million of bottles and jugs which leave the establishment in the course of a year, opinions being unanimously expressed that the spring and the methods of bottling were patterns of what all similar undertakings should be. At a luncheon, Justizrath Helliger, of Cologne, as President of the Council of the Act. Ges. Apollinarisbrunnen, spoke a word of welcome and greeting, and added some remarks which showed the many sided importance of the undertaking. In happily chosen terms Prof. Ott (Prague) returned thanks in the name of the guests.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIERNA, October 5th, 1903.

THE THERAPEUTIC AND DIAGNOSTIC VALUE OF TUBERCULIN.

Adler gave a long account of his experience in tuberculosis with "Tuberculinum versus Koch." During the past year he had treated twenty cases with it, but admitted that in its use a few precautions were necessary, and he gave an example of a female, 43, who had suffered for fourteen years from severe hemorrhages arising from bronchial catarrh, which finally would not heal. Having first seen it at this stage, he found infiltration of the right upper lobe with fever, night sweats, uncontrollable cough, and offensive sputum, in which were found tubercle bacilli. The breathing and palpitation were very troublesome, while her weight had rapidly diminished. After a short remission to bed the injection of tuberculin was given, it being 0.0001, and the treatment repeated for nineteen weeks, during which time 13 grammes of the tuberculin had been injected, the six last doses being 1 gramme each. After a few weeks from the beginning of the treatment the patient gradually improved till finally there was only a little dulness over the right apex without any vesicular râles being observed. All subjective symptoms had been restored, cough nil, and in every respect she felt perfectly well.

Three months later, however, the pause was disturbed by a repetition of the phenomena which have just been described. The same treatment was repeated but fever being present some time had to elapse in bed before commencing the injections.

The first dose was commenced with 0.00001 gramme gradually increasing to 0.0005 gramme.

He is inclined to believe that considerable judgment must be exercised in the quantity prescribed under different conditions. This, he tells us, was the reason of reducing the quantity from 0.0001 gramme. The first six weeks of the injection was given weekly, but never before the reaction of the former injection had disappeared. The temperature usually rose to 37.4 Centigrade, with headache, uneasiness and loss of appetite, although sometimes it was much higher with the increase of the dose. The greatest dose injected on this occasion was 1 gramme. The local reaction was confined to the points of injection over the extensors of the forearm. This varied from a slight reddening to phlegmonous swelling leaving tubercles behind, which would persist for some time. The patient can be allowed to move about when this treatment is proceeding if the doses administered be small, and the subject confined to bed the following day.

VENEREAL DISEASE.

The first Congress dealing with this painful subject has now come and gone, but with what results it is hard to predict. It is interesting to learn how the resolutions passed and the different opinions expressed as to the cause of so much venereal disease and prostitution. Some blame drink, some society, while others accuse trades and bad housing of the people. All or any of these causes may be argued as the first principle, but who is bold enough to prescribe the remedy? The Congress proposed that the benefit insurance societies of Germany should take the lead in this movement, but they refuse to have anything to do with it, as ulula virens of the Krankenversicherungsgesetze.

Schmölder endeavoured to give the Congress the legal knowledge necessary for their guidance, and proposed that any person knowingly conveying an infectious venereal disease to any healthy person, or endangering another by contact, should be and could be committed to prison for a year or pay a fine of 1,000 marks. If this law were strictly carried out at the present time in Germany it would have a salutary effect on reducing genital diseases. It was finally resolved that this should be increased to two years' imprisonment, and, further, that the subject should be deprived of all civil rights by striking his or her name off the roll. This statute is directly aimed at secret prostitution.
In the case of lawful solicitation the punishment has to vary between six months and three years.

The next point was marital protection. It was resolved that all benefit societies have on their sick sheets columns for this, and that warning should be given to the sufferer to take medical advice as to when to avoid marriage. In the discussion, Professor Erb declared that this could be carried too far. Abstinence in the passions has its limits, and he had seen much harm done in both sexes by total abstinence, particularly in hysteria and neurasthenia. He would counsel moderation, as the other extreme was certainly the worse of the two.

The social point dwelt on the homes of the people as inadequate for the cultivation of privacy in the family. It was proposed to press an inquiry, to be made in every town and city, to have the houses improved.

Becher thought that some of the reserve funds of the Kranken Kasse might be applied to the improvement of the dwellings, but the mayor of Mannheim questioned the legality of such a step.

The Operating Theatres.

CANCER HOSPITAL.

CARCINOMA OF THE PYLORUS COMBINED WITH LARGE CYSTIC DISEASE OF THE OVARY.—Mr. Bowes-Bowes of Oxford, a woman, aged 37, who had been sent to him suffering from constant vomiting and inability to take any solid food. She had been losing flesh for the last twelve months, and had suffered during that time apparently from violent attacks of dyspepsia. During the last three months she had been quite unable to take any solid food whatever, and had lived on milk and meat essences. About a fortnight before admission, at one of the attacks of vomiting she brought up a quantity of blood. On examination, Mr. Jessett found she had a tumour in the abdomen extending from the pelvis to two inches above the umbilicus, apparently containing fluid. On examining the pylorus nothing could be felt. There was no dilatation of the stomach, and it was difficult to account for the inability to take food. For signs, the uterus was drawn up and difficult to examine. Mr. Jessett recommended her to have the abdominal tumour (which was diagnosed to be ovarian) removed, and held out hope that possibly her stomach symptoms might improve after the operation. The tumour was removed, and proved to be a semi-solid ovarian tumour of the size of a large melon. At the operation he took the opportunity of examining the pylorus and found a hard mass, apparently scirrhous, in this situation. This mass was adherent to the surrounding parts. The adhesions were broken down and the pylorus liberated.

The patient was now, however, in such an exhausted condition that it was not deemed desirable to attempt either removal of the growth or a gastro-enterostomy. The abdomen wound was closed in the usual manner, and the patient returned to bed. Mr. Jessett said that this case presented some points of interest, as the patient had applied for relief for her stomach symptoms and did not seem to be aware of the large ovarian tumour which existed. He said that on several occasions when operating on malignant disease of the stomach, where it was impossible to remove the growth, he had found that the disease had apparently disappeared after the operation. The patient, in many instances returning to their normal vocations and enjoying good health. He quoted one instance in which he had performed gastro-enterostomy on a woman who had a growth as large as a fist firmly adherent, the patient lived for twelve years afterwards, the tumour entirely disappearing. In the other cases in which he had opened the stomach and found a large and apparently malignant growth occupying and ulcerating through the posterior wall of the pyloric end of the stomach, after the operation the patient had got quite well and complained of no further symptoms. It would be interesting, he pointed out, in the present case to watch and see if the growth found in the pylorus, after being manipulated and the adhesions torn down, benefited in the same way. On microscopical examination of a part of the ovarian tumour removed, it was pronounced to be of epithelial type, and was looked upon with great suspicion as to its malignancy or not.

The patient made an uneventful recovery and left the hospital a month after operation.

WEST LONDON HOSPITAL.

RUPTURED GALL-BLADDER.—Mr. Swinford Edwards operated on a boy aged 17, who had been admitted suffering from shock caused by having been run over in the street. A wheel of a cart was said to have passed over his mid-abdomen. The first urine passed was slightly blood-stained; the abdomen was slightly distended, rigid, and tender to the touch, especially over the left lumbar region. The diagnosis was bruise of the left kidney with possible laceration. The boy was kept in bed and watched, nothing more being done for the time. After a lapse of five days the abdomen became a little more distended, and the boy's expression was more anxious; the pulse was somewhat accelerated, but the temperature was not above 101°F. Looking at these conditions, Mr. Edwards thought an exploratory operation should be undertaken. An incision was then made in the left lumbar line, and level with the lumbar region, for the purpose of exploring the left kidney. On opening the peritoneal cavity a quantity of bile escaped. It was thus clear that the injury was to be found in the neighbourhood of the gall-bladder. A second vertical incision was therefore made over the situation of the gall-bladder, extending a short distance, and cartilage downwards to the outer side of the rectus muscle. The gall-bladder was found to be ruptured at its fundus, the rent being about three-quarters of an inch long. After having packed the operation area and well pulled up the ribs in order to facilitate closure of the rent, three interrupted Lembert's sutures were inserted and a gauze drain left in, extending to the sutured surface of the gall-bladder, and the two abdominal wounds were closed in the usual way. Before and after suturing the gall-bladder Mr. Edwards carefully drained off and swabbed out the extravasated bile. Mr. Edwards remarked that the lesion found was quite unexpected, for all the symptoms had pointed to damage to the left kidney; no doubt, he said, this organ had also been bruised at the time of the accident. He pointed out that there was no evidence of peritonitis, although no doubt this membrane had been bathed with bile for the past five days, and this showed that bile in itself is an aseptic fluid.

A fortnight after operation the boy was doing well: The wounds had healed well, and no kind of biliary fistula was left.

The Incorporated Society of Medical Officers of Health holds its annual meeting at 5 p.m. on Friday, October 9th, at the Holborn Restaurant, when Dr. Joseph Groves, of Carisbrooke, Isle of Wight, delivers his Presidential Address. The members dine together the same evening at the Holborn Restaurant.
heavy, that is, compared with the normal of the quiet, stagnant years that preceded the passing of the Act. Although we consider the moment ill-chosen, we should raise no objection to a departmental, or any other unprejudiced, committee inquiring into the subject of the cost were it not for two factors that give ground for serious apprehension. The first is, and we say it with regret, that the question is prejudged by the very person who appointed the committee—Mr. Walter Long. Mr. Chamberlain, who called Mr. Long’s attention to the increased expense, wrote to the Birmingham Guardians that he had conferred with the President of the Local Government Board; that that Minister had appointed a committee to consider and report, but that “in the meantime the President recognises the necessity for some change.” We cannot flatter ourselves into believing that Mr. Long considers the public vaccinator underpaid, and we feel very strongly that the consideration and report of the Committee should have been left unhampered by Mr. Long’s prepossessions. The other point on which we have misgiving is this: Are the committee taking the personal or written evidence of the public vaccinators themselves? This is of such prime importance that we should feel little hesitation as to their recommendations—in spite of their mandate—were they to hear the experiences of some thirty or forty public vaccinators from large urban districts. Than these nothing could be more pitiable in many cases. The public vaccinator is supplied by the vaccination officer with a list of unvaccinated children four and a half months old. He has to write to their parents informing them of his intention to visit, call at the appointed time, and, in a large proportion of cases, on his arrival, he finds the house shut and the people out. He calls again and again till he finds someone in, and then the excuses begin. Objections to the operation on principle; the child is not well; their own doctor will do it, and so on. All this and much rudeness he has to swallow for one shilling. If he can get the people to consent, he has to perform the operation with scrupulous care and attention to technique, subsequently ascertain the result, and attend the child (supplying all necessary medicines) if the arm inflame. For this he receives five shillings. We leave out of account the book-keeping, postage, and horseflesh involved, and ask if this is excessive pay for a scientific man? Were it not for the keen competition in our ranks and the altruistic desire of our profession to promote the public health, we doubt if men could be found to do so much for such niggardly remuneration. But this is not all. The public vaccinator is not a popular figure in the community in which his work lies, and his own practice is almost bound to suffer in the poorer parts of the large towns if his zeal to promote vaccination is as fresh and vigorous as it should be. He has, too, as his direct employers, the guardians, who nearly always contain among their number members elected for their uncompromising hostility to vaccination; these
gentlemen, we all know, are not distinguished by their suavity and sympathetic bearing towards the vaccination officials. The Local Government Board, from their experiences at Leicester, St. Pancras, and elsewhere, must be fully alive to the value of having tactful and energetic vaccinators, and of the great measure in which the success of the working of any Act depends upon the co-operation of the officials as distinguished from the guardians. Without dwelling on the advisability of employing special practitioners for performing public vaccinations, or of the suitability of the boards of guardians as the administrators of the vaccination laws (questions that we may return to at a future date), we warn the Government solemnly that any attempt to reduce the fees paid to public vaccinators will add one more difficulty to the many that already beset them. The feelings aroused by vaccination controversies are so acute that any misapprehension of them may easily lead to the defeat of any Government. No administration can afford to slight or over-ride its public officials.

THE RESPONSIBILITY OF RESIDENT MEDICAL OFFICERS.

The attainment of one of the coveted posts on the junior or resident staff of the great teaching hospitals is rightly regarded as a fitting end to the medical student's career, and as the goal after which he should earnestly strive immediately he is in possession of his diploma. The peculiar attraction which attaches to a house appointment lies not so much in the ever-varying sequence of cases and emergencies, the first treatment of which falls to the lot of the holder thereof, or even by virtue of its social status, as in its new and added responsibilities. The house physician or house surgeon is the centre of a little clique or "firm" of clerks or dressers, into each member of which he endeavours to inculcate that wholesome spirit of rivalry which is productive of the best work, and which conduces, in the end, to the true feeling of esprit de corps which characterises the men turned out from each hospital. He begins to appear before the public in something of that capacity in which he will shine in after life, and during his term of office he becomes acquainted with a very important branch of practical forensic medicine in the shape of the coroners' and the magistrates' courts. In the absence of the visiting staff he is personally responsible for the welfare and treatment of their cases in the wards, where he also has ample opportunities for displaying his powers of originality in therapeutic matters. In cases of real difficulty or emergency occurring at those times, he is able, in most cases, to obtain the superior advice of a resident physician or surgeon, whom, indeed, he is expected to consult in such circumstances. Very different, however, is the position of the resident medical officer in one of the smaller hospitals without a medical school. There he may be single-handed, or only have the assistance of one or two colleagues, who are generally junior to himself, and, when the visiting staff have made their rounds for the day, he is responsible for the whole medical conduct of the hospital. In many cases, and especially at night, or where telephonic communication happens to be wanting, he will have to act entirely upon his own initiative, and he must deal with emergencies as they arise. There are many conditions which, by reason of their extreme urgency, will not bear waiting while the surgeon is sent for, in which he must therefore act promptly, and without dallying or wavering, he must be prepared to perform tracheotomy or paracentesis thoracis at once if it be likely that the patient's life will be saved by so doing. From this it will be gathered that it is necessary for the resident officer that he should have had some experience, preferably by holding some house appointment at his own hospital, before he applies for a similar post at a smaller one. In countless ways will the capabilities of the resident medical officer be tested and the fitness with which he is endowed to undertake the responsibilities of his office gauged, not only by the medical staff but also by patients, nurses, and other officials, all of whom are quick to detect any evidences of his inefficiency. There is one point to which special attention may be drawn, namely, the great importance of judicious prescribing on the part of the resident officer, for he will speedily learn that the reckless ordering of expensive drugs and stimulants may bring him into unpleasant relationships with the governing body of the hospital, as was threatened recently at a provincial institution. It is generally considered that the trying of every new drug in the market in turn is rather a sign of the amateur, and the resident medical officer will certainly not be acting unwisely if he keep, as far as possible, to the older and more trustworthy methods employed by his superior officers in this as well as in other matters.

NATIONAL PHYSIQUE.

Mr. Benjamin Kidd has striven earnestly to demonstrate that the trend of evolution in the Western world—that is, in those nations that are still rising in the scale of mankind—is not primarily intellectual. He shows that when a nation becomes too highly developed intellectually its social efficiency suffers, and that it soon finds itself on the down-grade of the international plane. The ancient Greeks and the present-day French are the most striking examples of over-development of the national intellectual centres; the former have long since ceased to be, the latter are every day becoming less and less, a factor in world-politics. Mr. Kidd finds that the element that tends to give preponderance to any particular social organism is the character of the individuals composing that organism, the important feature in the character being the development of those qualities that lead the individual to subordinate immediate pleasure and gratification to the future interests of society. This may be so, and Mr. Kidd has certainly argued his case with an ingenuity and plausibility that do much to carry conviction.
There is, however, a factor which is so elementary, we might almost say elemental, in the structure of a successful nation that it deserves the greatest possible consideration. We refer to the physique of the individual. This may indeed be called the unit of national strength, for it is at the bottom of those characteristics that Mr. Kidd would have us cultivate—resolution, endurance, enterprise, and energy. The big intellect is often wrapped in a frail body, but the worker, the soldier, the colonist, and the administrator must be men primarily of sturdy build and resistant frame. Are we tending to produce and perpetuate such a race? There can be but one answer—the negative. Not only do the recruiting returns and opinions of Lord Kitchener on the later additions to the South African Field Force emphasise the difficulty of obtaining hardy young men for military service, but we see with our own eyes in the candidates that come up for life assurance, and in the habitus of the out-patient departments of our hospitals, lamentable evidence of the poverty of physical resource in the average individual. The Commission that has lately reported on the condition of children in the Edinburgh schools found that no less than 70 per cent. of them suffered from physical disability of some kind, and no less than 35 per cent. were seriously diseased. If these facts be true, or approximately true, of the rising generation all over the country, we may well consider ourselves in a parlous state. The Lord President of the Council has a committee sitting to make a preliminary inquiry into the statements that have been made as to physical deterioration of certain classes of the population, and we venture to congratulate the Duke on his bold and original action in so doing. But we do not need their report to know that under modern urban conditions an environment is being formed that does not, as Lord Rosebery has put it, “breed an Imperial race.” Mr. Booth and Mr. Rowntree have variously estimated the proportion of the population that is chronically under-fed, but both agree that the proportion is negligible one. Deficient air-space at home and insanitary domestic surroundings retard the development and stunt the stature of many more. Out-door recreation is only for the moderately well-to-do. To all those who have the cause of the Empire at heart, and to change a famous phrase, “We are all Imperialists now”; to all those who wish to live in a healthy, contented community; to all those who care for the poor and needy, we commend the wise words of Sir John Gorst, spoken at the opening of the Stockport Technical School. The ex-Vice-President shares with the Prime Minister a gift that is rare among public men, the ability to detach himself from the hurly-burly of the politics of the moment and regard facts in some sort of perspective. Sir John showed that the very justifiable cry for increased technical teaching will find nothing but a mocking echo unless the students be in a condition of receptivity—namely, a condition of intelligence and of health.

No such condition is possible unless they be trained with those ends in view in the primary schools. It is in those schools that the evils must be grappled with. The education authorities are now linked with the sanitary authorities, so that a co-operation formerly unknown will be possible in the future. It is by purging the stream at its source that the whole may be purified, and it is to those controlling the elementary schools that we must look for a system of practical instruction in the laws of health, and a system of remediying or relieving those defects and ailments that will handicap the child in his after-career. Much, too, can be done by reporting to the sanitary committee of the Municipal Council those facts that can be usefully dealt with by them. We would, therefore, urge that all the educational bodies in the country should appoint medical advisers, for without expert advice much of their energy may be misdirected. We believe that the Bradford School Board were the first to have their own medical officer; the School Boards of London and Manchester have followed their lead. These excellent examples may be taken as precedents by all the new authorities, and it is difficult to set bounds to the potentialities, local and Imperial, of such appointments, if the right men be chosen. The new education authorities will be left to mould the national character and to educate the national intelligence. Without quoting the hackneyed phrase of the satirist, we may remind them that their efforts are likely to be poorly rewarded if they neglect the national health. A sound frame of the individual unit is the basis on which all ultimate national success must be erected.

Notes on Current Topics.

The King’s Sanatorium.

The King has for long evidenced his unfailing interest in all matters relating to the alleviation of the sad lot of the poor consumptive, and when, nearly two years ago, it was known that £200,000 had been placed at his Majesty’s disposal, and was to be employed in the crusade against pulmonary tuberculosis, high hopes were raised both in the profession and among the public. But unfortunately, as is now generally agreed, his Majesty’s advisers have not succeeded in securing such measures as are likely to bring the greatest good to the greatest number of the King’s suffering subjects. Dr. Charles Reinhardt, in the October issue of the Health Resort, boldly faces the situation and openly claims that by the arrangements which have been adopted for the establishment of “The King’s Sanatorium” near Haslemere, there will be “a waste of lives and money.” It is said that the new institution cannot be ready for fully two years, and that the fabric alone will cost £60,000. Dr. Reinhardt argues from the standpoint of an enthusiastic believer in the advantages of a chalet colony settlement for consumptives. A good sleeping chalet of wooden construction, in-
cluding furniture complete, can be built for £30, though for a more permanent and better equipped structure, upwards of twice that sum could be well employed. The châlet system, although, of course, not without drawbacks, has the advantages that the patients are isolated, can enjoy complete privacy, and always a practically open-air life. In the palatial building now in course of erection through the beneficence of Sir Ernest Cassel, much money will be uselessly sunk. It is estimated the cost will work out at about £1,000 a bed. The £200,000 placed at the King's disposal, if used to establish sanatoria on the hut system, might have provided ten institutions capable of accommodating 100 patients each, and these could have been placed in different parts of the Kingdom. The total cost, including purchase of freehold of the necessary grounds and the equipment of furniture, would have been covered by £10,000 per sanatorium, which works out at the rate of £100 per bed. By such an arrangement only half the capital sum would have been absorbed, leaving £100,000 to be invested at interest to provide an annual income of £4,000 which, if allowed by public subscription and patients’ contributions would have provided for maintenance. Dr. Reinhardt also seeks to prove that during the two years that must elapse before “The Haslemere Palace,” as he calls it, will be ready, 7,800 persons will have been lost who might have been saved from much suffering and whose lives might have been usefully prolonged. The article to which we have referred contains much information concerning the construction of sanatoria upon the châlet system and certainly at the present time, when the accommodation available for the indigent consumptive is all too meagre, much can be said in favour of the hut or châlet method of establishing a hygienically constructed sanatorium.

The Silly Season and Obstetrical Science. In our last issue we published a short notice on a paper by Captain Lane, I.M.S., in which, in a clear process of reasoning from the particular to the general, he was able to announce some amazing “facts” in obstetrics. Says Captain Lane, “The child grows in utero in such a manner and at such a rate that at full term his size is proportional to that of the mother’s pelvis through which he has to pass in order to be born.” We are now surprised and delighted to find that our contemporary The Lancet, in whose columns Captain Lane’s paper first saw the light of publicity, is so impressed by his logic that, in its next issue, it has a leader of more than two columns, in which Captain Lane’s “very important conclusions,” and “investigations” on a series of first fifty and subsequently six patients are pronounced to be “of much value,” and are compared with those made by Budin, Pinard, La Torre, and others. The silly season is responsible for much, and we fear that it has drawn away our usually staid contemporary’s obstetrical editor to summer resorts, and has left in his place a most sarcastic gentleman. Seriously, however, we wish our contemporary would be a little more definite, and would tell us whether he is laughing at Captain Lane, or congratulating the obstetrical world on having so acute an investigator. Our contemporary’s leader says, in effect, that, granted a few impossibilities, Captain Lane’s investigations are of much value; but whether our contemporary wishes the impossibilities to be granted in order that Captain Lane’s laws may become possible, or whether it wishes to decry the importance of Captain Lane’s discovery and to insist on the right of a woman to have infants of different weights without at the same time altering the length of her true conjugate, is not plain. Perhaps it will devote another leader to explaining.

The Mystery of Memory. The most striking feature of the function which we call memory is that all the anatomical and physiological investigations of which the brain and nervous system have been the subjects have failed to throw the slightest light on the mechanism by which the brain registers impressions and holds them, more or less, at our disposal. Our knowledge furnishes us no clue to the nature of the indelible impress which passing events and even internal mental processes leave on the cerebral cell, and we are equally, it is impossible to be more, ignorant of the means by which we revive these impressions, either by an effort of the will or by automatic cogitation. Memory is currently described as evanescent, but though the capacity of recalling images may be difficult at a given moment, the permanence of the impress is shown by the odd way in which it is manifested quite unexpectedly after long intervals of apparent forgetfulness. The occultness of its mechanism is not less wonderful than its extraordinary comprehensiveness; in fact, there do not appear to be any well-defined limits to its scope. Fortunately there are faculties even more important than memory, for memory is not intelligence, although it furnishes the canvas upon which intelligence can work. It may attain an extremely high degree of development in a person who intellectually belongs to a decidedly low grade. This is in accordance with the law that the hyper-development of any one faculty is usually at the expense of the others, or of some of them. When by chance a maximal memory happens to be associated with a high degree of intellectual power we get the highest type of the human mind. By intelligence we mean the ability to co-ordinate rapidly-revived groups of correlated facts and their antitheses, and with these images before the mind to deduce certain logical conclusions. The strange effects of disease on memory only enhance the fundamental mystery and leave us in amazement at the inscrutable complexity and methods of the cellular machine. Through these morbid deviations we catch tantalising glimpses which lead us to hope that by-and-by we may succeed in discovering the thread which shall enable us to follow the mental processes through the cerebral labyrinth and establish the mechanism by which these marvellous results are achieved.
The Dangers of Sewer Gas.

That the risks run by workers in sewers are not inconsiderable is exemplified by a recent occurrence in South London, in which six men, who were engaged in building a new sewer, were overcome by the emanations of gas. They were all happily extricated, though not without great peril to their heroic rescuer. Exactly in what the poisonous properties of sewer-gas lie, when inhaled, has been a matter for some discussion, but there is little doubt that sulphuretted hydrogen is the most active ingredient in producing toxic effects upon its victims. When respired in small quantities, this gas gives rise to feelings of nausea, dizziness, weakness, and possibly diarrhoea, but larger amounts produce cardiac distress, cyanosis and collapse. The asphyxia is due to the action of hydrogen sulphide upon the haemoglobin of the red corpuscles, by which they are deprived of their power as oxygen-carriers to the tissues. The gas is, moreover, very slowly eliminated by the lungs. In other instances, carbonic acid seems to have been the cause of the fatal issue. Some authorities, however, consider that the toxic action of sewer-gas consists in paralysing the nervous centres. The organic constituents of the emanations from sewers appear to possess some harmful properties which act injuriously upon the animal economy. Thus, the belief that a certain variety of sore-throat is liable to be contracted in the neighbourhood of a "bad drain" is a deeply-rooted one, but that it is not altogether without scientific foundation is proved by the fact that micrococci have been discovered in the air around the offending spot, and septic organisms can frequently be cultivated from the fauces in such cases. Some degree of immunity against this infection must be acquired by workmen, or otherwise these forms of toposillitis would be far more prevalent among them than they really are. The dangers of poisonous gases still remain, and these can be minimised, to a great extent, by efficient ventilation.

Infantes and Opiates.

We have many times alluded in these columns to the lamentable sacrifice of infant life caused through the administration by ignorant parents of totally improper food or of "soothing" draughts to their unfortunate offspring. Nourished by doubtful milk, hulled into an unnatural quietude by powders or draughts which are advertised to ensure perfect freedom from restlessness, it is a wonder that as many of them survive as they do. Under such euphemistic and deceitful titles as "Comforter," "Friend," or "Treasure," these concoctions find a ready sale among mothers whose lives are worn by the incessant cryings of their babies. But now and then fatal results occur, and, for a time, the eyes of the public are opened to the dangers of these nostrums. At an inquest recently held at Earlסטon, near Warrington, upon a child aged seven weeks, it was stated that it had been given only a half-teaspoonful of one of these comforting draughts, a "bottle" of which was shown to contain three drachms of the syrup of poppies. Although this is, of course, one of the weakest preparations of opium, yet the quantity therein is apt to be uncertain, and, moreover, the peculiar susceptibility of young infants to the drug must always be taken into consideration. Where there is actual necessity for checking haemorrhage or albuminous discharges, small quantities may be given for a short period combined with some stimulant, but its medicinal and haphazard uses are two very different matters. It is worthy of note that, although the jury considered the person who sold the mixture censurable, yet the coroner is reported to have offered no comment, in view of possible proceedings by the Pharmaceutical Society. A few remarks from this official might have had more weight with the public and have assisted in checking this abuse.

The Trinidad Epidemic.

Vaccination is responsible for one disadvantage at least. Its effect has been such that medical men have almost lost the faculty of recognising small-pox. There is probably no infectious disease so capable of exact diagnosis as is variola to those familiar with it in both its natural and modified forms. For this reason it seems extraordinary that no definite conclusion can be arrived at with regard to the nature of the epidemic that lately prevailed in Trinidad, unless we assume (as we have no right to do) that the medical officers of the island were not familiar with small-pox. Even had this been so, an epidemic attacking over four thousand people would have rendered them sufficiently familiar with the disease they were dealing with to be able to decide whether it did, or did not, accord with the classical descriptions of small-pox. The opinion entertained at Trinidad is that the disease was neither small-pox nor chicken-pox, and Drs. Dickson and Lassalle, who have just published a communication on the subject, give it the name of varioloid varicella. Perhaps we ought to call it the "fifth disease." Their description of the clinical course is clear and careful, and several features are markedly different from those of ordinary variola. The two points that strike one most forcibly are that the rash appeared in crops, and that second attacks were not uncommon—twelve instances of recurrence having come under notice. The exceedingly low case-mortality, 0.44 per cent., is certainly unlike that of any epidemic of variola that we have met with, but modified small-pox is often a very benign disease, and the occurrence of so few deaths is not necessarily fatal to the hypothesis of variola. The distribution of the rash, some of its characters, the complications, and the effect of vaccination in the incubation stage are strongly reminiscent of true small-pox, and the age-distribution of the patients is almost exactly what one would expect in an epidemic of small-pox in a well-vaccinated community. A similar disease had existed in Venezuela for some time before Trinidad was
invaded, and Spalding, of Chicago, has described analogous outbreaks in the States. In Barbadoes, at the same time as Trinidad was attacked, frank small-pox was prevalent, and there was a good deal of feeling at the ports of Barbadoes being put under restrictions whilst those of Trinidad were left open. The question turned on points of clinical diagnosis, and the Trinidad doctors stuck to their opinion, as they had every right to do. We could wish that one of the schools of tropical medicine had sent out an expedition consisting of acknowledged experts at the time of the epidemic, for we should then have had a solution of one of the most interesting problems in the natural history of disease that have come under our notice in recent years.

Light in Dark Places.

A well-known philanthropist, speaking of deaf-mutes, said that Nature had inflicted upon them but one defect—imperfect hearing. That was too bold an assertion. The deaf-mute not infrequently has other limitations—mental deficiency and imperfect vision, for instance. To overcome this, it is generally hopeless; the latter so difficult that even partial successes are few and far between. A totally-blind deaf-mute can only be placed en rapport with his surroundings by the sense of touch, taste, and smell, and acuity of the latter can seldom be cultivated to a degree that is of any practical help. It is therefore only through the touch that any real communication can be made, and for this purpose neither of the two recognised systems of combating deaf-mutism, the oral or the manual, is available. Extraordinary demands must be made on the patience, intelligence, and sympathy of both teacher and pupil before any progress can be made, and for a blind deaf-mute to attain such a degree of intelligence as to obtain honours in University examinations is no mean triumph.

"The Story of My Life," by Helen Keller, which has just been published, is an autobiographical account by a blind deaf-mute of her passage from darkness to light, and reveals to us a psychological study of unique interest. Starting with the mind a complete blank, the little girl was taught to recognise objects; then to understand the principle of the name; thence general names, and—most striking of all—moral ideas. Finally the power of speech was elicited. She was educated, always through the medium of her indefatigable teacher, Miss Sullivan, at Cambridge, U.S.A., and the devices contrived by this clever lady to convey information on such subjects as geometrical problems form a chapter of fascinating interest. Academic distinction is not the only evidence of Miss Keller's extraordinary ability, for she is an authoress of considerable power, and her reflections are always sagacious. She is not, of course, the only blind deaf-mute who has been educated, as we all remember the story of Laura Bridgeman, in Dickens' "American Notes," but she is by far the most successful product of the teacher's art of whom there is record. Dumas was astonished at the facility with which the inhabitants of Sicily could communicate by signs; we wonder what he would have thought of Miss Keller?

A Testing-Home for Drunkards.

The ways of religious people, when they deal with things medical, appear passing strange to the man of science. Many of their ideas are excellently conceived in the interests of humanity, but their methods are often puzzling. We confess we read with some bewilderment of the new enterprise on which the Church of England Temperance Society are embarking. This beneficent society are starting a "testing-home," whose object will be to test drunkards who have just come out of inebriate retreats with regard to their newly-acquired resistance to the enemy. We do not know quite how the "home" will be run. Perhaps an official will meet the quondam toper and invite him to have a drink, or sparkling whiskies-and-sodas will be left casually on side-boards to see if they disappear. A more insinuating plan would be to put gin in the water-bottle and see if the testee spurns the evil thing when he raises his glass to his lips. What is to happen if he swallows it? Will pressure be brought to bear on him to return to his retreat, or will he be bundled off to a certain institute to undergo a "cure" which at least one ecclesiastical dignitary advocates by sermon and pen? We shall be much interested to hear more of the "testing-home" and the plan that will be followed there. We can hardly credit the Church of England Temperance Society with the ingenuity such a scheme suggests. We have always thought the best plan with a reformed drunkard was to keep him from any temptation to test his principles, and we have learned nothing lately in our studies in inebriety to suggest any other method. We note that £150 is needed to start the home, which, it is naively remarked, "will be the first of its kind in the country." We pass every day a good many "testing-homes" for those addicted to drink, but they are not run by the Church of England Temperance Society.

Orthostatic Albuminuria and Movable Kidney.

The pathology of the so-called "cyclic" albuminuria has always been attractive to clinical workers, probably on account of its mysteriousness, and yet very little real information regarding its true significance has been forthcoming. The name "orthostatic," as Dr. G. A. Sutherland points out, seems to be the most descriptive, as indicating its postural characteristics, and in a paper contributed to the American Journal of the Medical Sciences he narrates fifteen cases in which this variety of albuminuria was associated clinically with movable kidney. Two of these were in males and thirteen in females. In five both kidneys were movable, the right one being affected in ten. Abnormal pulsation of the abdominal aorta was felt in nine cases. The average age was 10 and
the oldest 14. Pain was complained of in two-thirds of the cases. The connection between the two morbid conditions is most important and suggestive. Dr. Sutherland believes that the daily surcharging of the renal organs with venous blood is the chief factor in producing both the albuminuria and the displacement, though the influence of some congenital weakness in the attachments of the kidney is not overlooked. An analogy is traced between some of the symptoms and Graves' disease as occurring in adult life. It is quite possible that movable kidney will be found in a greater number of cases of orthostatic albuminuria than has hitherto been done, while these observations tend to shed a new light upon this little understood affection. With regard to treatment, it is asserted that simple bandaging of the abdomen is generally sufficient to relieve the symptoms in children, without resorting to operative measures.

The Introductory Lectures.

This autumn's introductory addresses afford evidence of a desire to break the monotony of these oratorical performances by requisitioning the services of eminent persons who might irreverently be termed "outsiders." True, Sir Charles Wyndham revealed to our astonished ears that he is in possession of diplomas entitling him to registration, so that technically he belongs to the fold although he does not avail himself of his right to tamper with the constitutions of his fellow beings. His bright, sparkling address to the students of the Charing Cross Hospital was a pleasant variation on the hackneyed theme, and he contrived to drive in some very practical lessons. We can find less justification for the address by Sir A. Cockburn at King's College, since it had a distinctly political bias with the very scantiest medical bearing. Interesting it may be, but appropriate it certainly was not. The choice of a dentist to deliver the address at Middlesex strikes one as odd, though it may be conceded that there is a close relationship between defective conditions of the teeth and certain morbid constitutional states. The relationship of the military medical service to the civil population, the theme selected by Dr. V. W. Low at St. Mary's, is a subject of immediate interest, though less, perhaps, to the neo-student, whose field of mental vision does not as yet extend beyond the horizon of the examining boards, if, indeed, as far as that.

Is Nerve Energy Electricity?

The question of the identity of nerve energy with electricity has long been regarded as approximately settled in the negative. If, however, one scans the data upon which this conclusion has been arrived at it becomes apparent that they are lacking in precision. The argument based on the alleged difference in the respective rates of transmission of nerve and electric impulses is open to the objection that both estimates are at best only approximate; moreover, since the experiments by Du Bois Raymond and Helmholtz great advances have taken place in our knowledge of the phenomena of the transmission of electrical impulses, more particularly in cables. Then, again, the statement that the insulation of nerves would not suffice to prevent the escape of an electrical current is based on a misconception. Insulation, we now know, is merely relative, and the weaker the current the less tendency is there for it to quit the conducting medium. It is not only conceivable, but likely, that our muscular apparatus is so constructed as to respond to exceedingly feeble stimuli, since the latter, after all, only inaugurate the contraction and do not actually carry it into effect. The similarity of the arrangement and distribution of the nerves is presumptive evidence of the electrical nature of the current, and if this be denied we are confronted with the difficulty that we are assuming the existence of a form of energy unknown to physicists. It ought to be possible to settle this vexed question once for all. We know, at any rate, that even feeble currents of electricity excite muscular contraction, and it only remains to show that similar currents may emanate from the nerve centres. This, with the extraordinarily delicate apparatus at present available, ought not to be impossible.

A Simplified Etymology.

Theoretically desirable though it may be to do our best to simplify the orthography of the language which we use in common with so many of our race in other parts of the world, we note a spirit of conservatism on this side of the Atlantic in regard to all suggestions having for object the elimination of superfluous syllables and letters. Our American cousins, having no history and possessing no proprietary right to the language, being, in fact, only lodgers, so to speak, display no sort of reluctance to tamper with the ridiculous redundancies which our forefathers have bequeathed to us, and which our schoolmasters persist in maintaining to the discomfort of the scholars and the curtailment of more useful studies. When the American author or editor is unable to unearth any etymological justification for a change in this direction he falls back on the Biblical paraphrase that language was made for man and not man for the language. Consequently he accepts "dilution" for "dilatation," assassinates diphthongs in cold blood, and trims adjectives of all superfluous syllables without that regard for symmetry to which previous training inclines us to accord a foremost place in such matters. In virtue of the law that men will not expend more energy in pursuit of a given purpose than is absolutely essential to that object, it is highly probable that, whether we like it or not, we shall ultimately have to adopt the abbreviated Transatlantic orthography. But inertia is a power in itself, so that this change may not come to pass within our own day, or even within that of our children.

Mr. Tobin, Surgeon to St. Vincent's Hospital, delivered the introductory address to the Medical Session yesterday, at St. Vincent's Hospital.
Hygiene and Hotel Construction.

It is interesting to watch how each advance in sanitary construction is applied to increase the healthfulness and safety of the monster hotels which are springing up, not only in the Metropolis, but all over the country. Ameliorations of detail which were originally devised to secure the asepsis of operating theatres are beginning to be applied with the same object in these caravansaries, as shown by the introduction of polished similiar marble or glazed cement walls, devoid of projections calculated to catch and retain dust, polished floors with mats that can readily be shaken free of their microbial contents, and so on. Students of hygiene would find a valuable object-lesson in an inspection of such an hotel, for instance, as the new Midland Hotel, at Manchester, in respect of modern methods of ventilation and in the perfection of sanitary appliances of all kinds. Subtle details such as rounding off the corners to facilitate the cleansing of the floors have, it is true, not as yet entered into the designing brain of the architect, but sooner or later they will do so and the first-class hotel will be structurally as potentially aseptic as the operating theatre. Private dwellings lag far behind in this respect, partly, no doubt, because it is difficult to get builders to recognise that the extra cost entailed by hygienic construction, economical heating and efficient ventilation is by no means prohibitive and is more than compensated by the additional value conferred upon the dwelling by attention to these details. However, it is a great thing to accustom the public to these improvements in public buildings, since little by little the lesson is learned and a desire is created to take advantage of the latest sanitary ameliorations.

Puerperal Mortality in Hospital and Private Practice.

In his address to the students of St. George’s Hospital, Dr. Dakin pointed to the fact that during the last forty years the proportion of deaths from puerperal causes to the total births had in no wise diminished, in spite of the immense reduction in deaths from such causes in hospital practice. He infers that practitioners do not avail themselves of the security afforded by antiseptics to ward off infection. We are not concerned to deny that such may be, indeed is, the case, but obviously it is unfair to throw the whole blame on the practitioner. To establish his share of the responsibility it would be necessary to ascertain what proportion of the total number of infants are born under his supervision, and then to find out what proportion of such parturients died from puerperal infection as compared with the residualy number who do not obtain medical assistance at all. The chances are that an extremely high relative mortality in the latter class would considerably reduce the share which would remain attributable to shortcomings on the part of the practitioner. Then, again, the best-intentioned and most skilfully directed efforts at antisepsis on the practitioner’s part are liable to be frustrated by the filthy environment, and the total disregard for personal cleanliness, which obtain in the lower classes. With these reservations we are fully disposed to concede that much more might be done to practise, and also to preach, the gospel of personal cleanliness among the poor. The obstetric practitioner ought to see that he, at any rate, is free from the reproach of microbial impurity, for by so doing he obviates a very possible and, it may be, a very frequent source of fatal infection.

The Example of Zadig.

Neglect to interpret aright or failure to recognise the more trivial and apparently unimportant symptoms of disease not unfrequently leads to the misapprehension of the true nature of the case, if not to actual error in diagnosis. While it is, of course, essential to take a broad view of the morbid phenomena in general, and to include them in one comprehensive survey, it is also a sine quâ non of success that due attention be paid to the study of minute details. In alluding to the more common causes of failure to make accurate diagnoses, Mr. W. H. A. Jacobson, in a paper read before the Medical Society of Manchester, and published in the Guy’s Hospital Gazette, gave especial prominence to the neglect of the example of Voltaire’s hero as being probably the chief. It is not given to every practitioner to possess the detective genius of a Sherlock Holmes, nor is the marvellous intuition of a Zadig seen save only in a privileged few, but even the minutest points are open to the observation and inspection of all, and it is from these that sometimes the most important conclusions may be drawn. Mr. Jacobson cites some interesting cases in which such minor symptoms as pallor, tremor, and strabismus were more or less overlooked, or, at any rate, not taken into sufficient consideration, with unfavourable results to the patient. As an illustration of the value of small facts a case is narrated in which the diagnosis of tuberculous cystitis was confirmed by the existence of a minute weeping sinus over the eighth rib on the left side, which suggested quiescent caries. On the other hand, too much importance may be laid upon the presence of trivial symptoms which really have no bearing upon the case, and which, if followed up and made much of, may only mislead and confuse. It is only by the careful and systematic examination of every symptom in the body that mistakes such as these may be avoided.

Veterinary Service and Jury Service.

Our compatriots, the veterinary surgeons, are desirous of sharing in the immunity from jury service conferred by law on duly qualified medical practitioners, and during the last few days the question has been brought to the front in several parts of the country. With one exception, however, the authorities have declined to recognise the medical status of the “vet.,” who will consequently be constrained to serve his country in this useful if humble capacity. Nor, would it seem, could any other decision have been arrived at. The reasons which prompted the Legislature to exonerate medical men from jury service cannot fairly be
said to apply to those who are entrusted with the medical care of cattle and domestic pets. Rightly or wrongly, it is customary to attach extreme importance to human life, and the idea that one such life might be sacrificed in the absence of the medical practitioner at the courts is repugnant to our feelings of humanity, but no such delicacy is felt at the idea of the administration of a bolus to a dyspeptic cow being delayed by the temporary absence of the veterinary surgeon.

Professor Ferdinand Hueppe, of Prague, gives the Harben Lectures at King's College, London, on October 8th, 12th, and 15th.

Dr. G. B. Mason, who was the founder of the West India Club in London, has been appointed a Medical Officer of the Leeward Islands.

MRS. GARRETT ANDERSON, M.D., has published an analysis of the data presented in the Report of the Metropolitan Asylums Board on the recent epidemic of small-pox.

Professor von Behring is pursuing experiments upon new-born animals, in which he seeks, by supplying them with a suitable solution of tuberculous virus in their food, to render them immune against tuberculosis.

Special Correspondence.

[From our Special Correspondents.]

SCOTLAND.

APPOINTMENT OF DR. DAVID HEPBURN TO THE CHAIR OF ANATOMY AT CARDIFF.—Through Dr. Hepburn's transference from the University Anatomy Department to that of University College, Cardiff, Edinburgh University loses one of the best known and most popular of her teachers. Dr. Hepburn has been the principal demonstrator of anatomy since 1885, and while to all his old students the anatomy rooms will seem changed indeed, without his presence in them, he takes with him to his new work the heartiest good wishes from all those he has taught, whose only surprise is that promotion has dallied in coming to one who so well deserved it. Dr. Hepburn's career, both as a student and later as an original investigator, was a brilliant and successful one. He was a Blaney prize-man, and a University Gold Medallist on the occasion of obtaining his M.D. After graduation he served as house surgeon and house physician in the infirmary, and then devoted himself to his life's work—anatomy—in which he has made many important investigations, both on special points in human anatomy and in the comparative anatomy of birds, apes, and the cetaceans. He was well known to all students, not only as a painstaking demonstrator in the dissecting rooms, but as a lucid and successful lecturer; while his genial nature and musical abilities brought him into contact with the students outside his own department, and he was in great request and ungrudgingly gave his services at all manner of university concerts and similar functions. He was also an enthusiastic volunteer, and did much to further the success of the volunteer movement among Edinburgh students. All old Edinburgh men will join in congratulating Cardiff on its new professor.

BELFAST.

THE TYPHOID QUESTION.—On Thursday last an interview with Alderman Dr. Graham, Chairman of the Public Health Committee of the Corporation, was published in the Northern Whig, in which this gentleman gave his opinion on a number of questions relating to the prevalence of typhoid in the city. He stated that while differing from Professor Lorrain Smith in some minor details, he was in general agreement with him in his report. One of the great defects in the treatment of infectious cases in Belfast he considered to be the want of proper hospital accommodation, and the consequent large number of such cases treated in their own homes, each case becoming a centre of infection. Unpaved streets, which imposed on about properly cleansed, Dr. Graham also believes to be a serious defect in the city. The sale of shell-fish is also a matter requiring strict supervision, many tons of periwinkles and cockles being gathered from the polluted mud flats of Belfast Lough every year, and sold in the city and surrounding country. The common plan of keeping pigs in back yards is open to serious objection. The present regulations in Belfast allow the keeping of pigs at a distance of over fifteen feet from a dwelling house. The use of female sanitary inspectors is strongly advocated by Dr. Graham. He believes they have much freer access to the homes of the poor, and can do more to instruct them in sanitary matters than men can. There are already two female sanitary officers employed in the city, with most excellent results. Careful attention is now being paid to all new house drains, and old ones are being reconstructed at the rate of 3,666 annually. Of the last 11, the rate per 1,000, that the death-rate from zymotic diseases and from phthisis was decreasing, and that he hoped all parties would work harmoniously together, so as to remove from our city the reproach of having the highest typhoid death-rate of any city in the world." Professor Lorrain Smith's report is to be discussed at the next meeting of the Corporation. That the meeting is likely to be a lively one was evident from a preliminary skirmish which took place at the meeting of Council in committee last week. It seems as though the report, which is the outcome of two years' laborious investigation, were to be used chiefly as a missile for the members of the Corporation to hurl at one another's heads, metaphorically speaking.

COUNTY DOWN ASYLUM.—At the last meeting of the Board of this asylum, an election was held for the post of junior medical officer, and the result was a return for Mr. Hoare, with 30 votes to 15. There were six candidates, and Dr. Wm. R. Ringland, of Crossgar, was elected to serve for the probationary period of six months.

OBITUARY.

MR. W. J. WALSHAM, F.R.C.S.

The announcement of the death of this distinguished surgeon, at the early age of fifty-six, will come as a shock to his colleagues at St. Bartholomew's Hospital and to the many friends and patients by whom he was so greatly esteemed. Past students will think of him most in connection with his small Manual of Surgery, which was the favourite handbook a few years ago, and his "Surgical Pathology," to the present day. Formerly he will be remembered as one of the most skilful and painstaking operators St. Bartholomew's has produced. As his death occurred only as this journal was going to press, we must defer a more extended notice until next week.

DR. R. S. CARNEGIE.

We regret to announce the death of Dr. R. S. Carnegie, which took place in Montréal on the 20th ult. Dr. Carnegie was an M.D. and a B.Ch. of the Dublin University since 1890, in which year he became surgeon in the Dominion Steamship Company, in whose service he remained for ten years. He then joined the Allan Steamship Company, and during the South African War made ten trips in charge of the SS. Bavarian to Cape Colony. As an evidence of his courtesy and
kindness, we may mention that he obtained a testimonial from some hundreds of Boer prisoners, which was signed by some of the most distinguished leaders of the Republics.

Medical News.

Medical Sickmess and Accident Society.
The usual monthly meeting of the Executive Committee of the Medical Sickmess and Accident Life Assurance Society was held at 429 Strand, W.C., on the 25th ult. There were present Dr. de Havilland Hall, in the chair; Dr. G. A. Heron, trustee; Dr. J. B. Ball, Mr. G. Brindley James, Dr. Major Greenwood, Mr. F. S. Edwards, Dr. F. R. Mutch, Mr. H. P. Symonds, Mr. Wm. Thomas, Dr. F. J. Allan, and Dr. W. Knowles Sibley. The sickness experience of the society during the summer months has been exceptionally good, and has about made up for the heavy amount of sickness claims which always has to be met in the spring of the year. The number of new entrants to the society has been larger than for some years past, and it is clear that the advantages offered by a society composed exclusively of medical men and carried on entirely in their interests, are becoming more clearly recognised. A considerable addition has been made to the funds during the first half of the year, and the valuation to be made at the close of the current year will undoubtedly show a great increase in the financial strength of the society. Prospectuses and all information on application to Mr. F. Addison, Secretary Medical Sickmess and Accident Society, 33 Chancery Lane, London, W.C.

Five Deaths Under Anesthesia.
A child, aged 23 months, died last week under gas at the Chelsea Hospital for Children during an operation for the removal of adenoids. The parents asserted that they had formally objected to the use of an anesthetic, but this statement was subsequently shown to be inaccurate. An exonerating verdict was returned. Another death during an operation for the removal of adenoids occurred at Southend, the victim being a lad, aged 15. The anesthetic used is not mentioned in the report. The jury appended to their verdict an expression of sympathy with the doctors concerned. A girl, aged 6, died under chloroform administered for the purpose of facilitating the opening of an abscess at the Children's Infectious Diseases Hospital. The verdict at the inquest was "Death under chloroform." At Manchester a woman, aged 23, died under chloroform administered for the purpose of a dental operation, and the coroner sharply criticised the use of such a powerful drug, especially when only one practitioner was present, for such a surgical operation. A verdict of "Death by misadventure" was returned. To wind up this lamentable list of catastrophes a collier died under chloroform at the North Staffordshire Infirmary while undergoing amputation of a finger. The medical men were exonerated from all blame.

Payments to Public Vaccinators.
The Departmental Committee appointed by the President of the Local Government Board to inquire and report with regard to the payments made to public vaccinators and vaccination officers under the Vaccination Order, 1898, recently held a meeting. Mr. F. W. Dimbleby, Senior Vice-President of the Association, and Mr. W. F. Vulliamy, a member of the Association and Clerk to the Ipswich Board of Guardians. The committee have already heard the evidence of the official witness, Mr. W. V. Conolly, Principal Clerk to the Public Health Department of the Local Government Board, at the Guild of St. Luke.
The annual medical service at St. Paul's, organised by the Guild of St. Luke, will take place on Wednesday, the 21st inst., at 7.30 p.m., when the sermon will be preached by Prebendary H. M. Villiers, vicar of St. Paul's, Knightsbridge. As heretofore, all doctors who are graduates, or Fellows or members of the Royal College of Surgeons, are asked to attend in academic robes. The music will be rendered by the London Church Choir Association. Admission to the space under the dome will be by ticket only.

City of London Crematorium.
The foundation stone of the City of London Crematorium will be laid at Ilford on Wednesday, the 14th inst., by Mr. R. W. Edwards, the chairman of the Sanitary Committee, a body which acts as the Burial Board for the City. The crematorium will cost, when completed, £7,000.

The Jenner Institute of Preventive Medicine.
The governing body announced that the necessary legal formalities in connection with the change of name of this institute have now been completed, the Board of Trade having sanctioned the new name. The institute will, therefore, now be known as the "Lister Institute of Preventive Medicine." The address, Chelsea Gardens, S.W., remains the same.

A Faith Healer Sent to Prison.
A BELIEVER in faith healing and a disciple of that arch-quack, Dr. Dowie, was sentenced to a month's imprisonment last week at Quarter Sessions of the Peace for failing to provide medical attendance for his little girl, who had sustained a fracture of the clavicle.

Conjoint Examinations in Ireland.
The following candidates have passed the preliminary examination by the Royal College of Physicians and the Royal College of Surgeons:
Honours.—H. G. M. Miles.

West London Medical-Chirurgical Society.
Officers and Council for 1904-1904:
President.—Dr. Seymour Taylor.
Vice-President.—Mr. G. E. Twynam, W. P. Mallam, Dr. W. T. Gardner, Mr. C. B. Keetley, Mr. W. P. Barratt, Dr. G. H. D. Robinson, Mr. J. R. Lunn, Dr. E. Furniss Potter.
Council.—Dr. G. P. Shuter, Mr. R. Pollock, Dr. A. M. Ross Sinclair, Dr. A. Whitfield, Mr. Garry Simpson, Mr. Percy Dunn, Mr. McAdam Eccles, Dr. W. H. Walter, Mr. E. P. Paton, Dr. A. J. Rice Oxley, Mr. Tennyson Patmore.
Treasurer.—Mr. T. Gunton Aldeston.
Secretary.—Dr. C. Butter, Dr. G. Elliot.
Librarian.—Mr. H. W. Chambers.
Editor of Journal.—Dr. Leonard Dobson.
Editorial Secretary of Journal.—Mr. J. G. Pardoe.

The Royal University of Ireland.
The Second Examination in Medicine.
The examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:—
The above candidates may present themselves for the further examination for honours.
The following candidates were exempted from further examination in chemistry:—
William T. Henderson, Joseph A. O'Halloran.
Letters to Correspondents, Short Letters, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Refusals.—Reprints of articles appearing in this journal can be had a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

J. S. F. The Japanese method of inducing anesthesia by compression of the carotids has not, so far as we are aware, been turned to account in this country, nor, so far as we believe, is it likely to be. It is unpleasant to the subject, and might conceivably be followed by disagreeable results.

UNREASONABLE.

Doctor—Walker is the most unreasonable man I ever saw.

Friend—Why? asked the captain.

Says it is so good in equally, answered the commodore.

Memo.—The "facts" of the case as reported are too improbable to bear publication. If you can obtain first hand evidence in support of your contention we shall be prepared to reconsider our decision, which is at present adverse to acceptance.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 7th.

Ophthalmological Society of London (20 Hanover Square, W.)—8 p.m. Specimens will be shown by Dr. A. Dora (for Dr. Batchelor, Dunedin) and others. Short communication—Dr. Hellige—Case of Abdominal Peritonitis with Partially Ruptured Pregnant Tube. Papers—Mr. Malcolm—An Operation for Extra-uterine Fettation between the Fallopian Tube and Ovary. Dr. G. B. Long—A Case of Intestinal Tumour in a Gentleman of 60, with a history of Nephritis.

BRITISH BOTANICAL SOCIETY (20 Hanover Square, W.)—8 p.m. Specimens will be shown by the President and Dr. Macnaghten-Jones. REMARKS ON MORVAN'S DISEASE
AS AN EARLY MANIFESTATION OF SYRINGOMYELIA.

By WILLIAM MURRELL, M.D., F.R.C.P.,
Physician to the Westminster Hospital, Lecturer on Clinical Medicine
and Joint Lecturer on Medicine in the Westminster Hospital Medical
School.

In previous papers (a) I have referred to various morbid conditions commonly mistaken for rheumatism. In this category should be included Morvan’s disease, a group of symptoms described by Dr. Morvan, of Lannilis, in Brittany. His paper (b), published in 1883, is entitled “De la Parésie Analogésique à Panaris des Extrémités supérieures or “Parési-Analgésie des Extremités supérieures.” He speaks of paresis with analgesia of the upper extremities affecting first one side and then involving the other, associated always with the formation of one or more whitlows. His attention was drawn to the subject in a curious way. A man, some sixty years of age, consulted him respecting a whitlow with necrosis of the ungual phalanx. The patient was by no means of a heroic disposition, and very unwillingly consented to surgical interference, but on free incision being made for the removal of the diseased bone, he made no complaint, and declared that he felt no pain. In the course of years Morvan collected seven similar cases, five of them in men and two in women. The occupation of the men is not stated, except in one case, a farmer, but as the patients resided at Guiseémy, Ploudalnènezeu (? Plouldalsmezeau), Plouider, Saint-Pabu, and Plonguenneau, villages not far from the coast, it seems not improbable that they were fishermen. I mention this because I am informed that painless whitlows are not infrequent among the fisher-folk of the east coast of Scotland. Morvan, in his description, states that the disease affects the upper extremity only, being confined to the forearm and hand. One of its chief characteristics is pain of a neuralgic type. He emphasises this point, and says:—“La maladie débute par les douleurs neuralgiques,” and he adds, “les douleurs neuralgiques précédent par crises.” This is followed by partial paralysis of the muscles and analgesia, terminating ultimately in whitlows with necrosis of the phalanges. The hand becomes swollen and congested, and is marked by deep cracks or fissures, especially in the palm. The growth of the nails is affected, and they become brittle and irregular in shape. The disease runs a chronic course, and rarely attacks the lower extremities. The neuralgic crises after some years undergo amelioration, but the paresis and analgesia persist, and there is little prospect of a cure.

The symptom-pictures of syringomyelia, but Morvan makes no mention of this disease, which is perhaps not surprising, as Isaac Bruhl had not then published his monograph on the subject, and it was not until some two or three years later that the condition attracted general attention. Morvan, however, discusses at some length the differential diagnosis between his disease and the symmetrical gangrene of Maurice Raynaud, the erythromelalgia of Weir-Mitchell, the sclerodactylie of Ball, and the “panaris nerveux” of Quinquand. Another disease for which it might possibly be mistaken is anaesthetic leprosy. It must be remembered that although cavities in the cord have long been recognised as pathological curiosities, the distinction was not at first established between hydromyelus and syringomyelia. In the former, as is now well known, there is a central dilatation of the canal lined with epithelial cells, whilst in the latter there is a disintegration of the cord, due to infiltration of its substance with gliomatous tissue, the cavity being surrounded with gliomatous tissue and its walls composed of neuroglia and fat cells. Hydromyelus is a congenital malformation, whilst syringomyelia is an acquired disease.

Whether Morvan’s disease is to be considered a distinct affection or a symptom of syringomyelia is a subject which has been much discussed. Allen Starr (a) in his original paper on syringomyelia makes no mention of Morvan’s contribution, but in a more recent article states that it is now thought to be a variety of syringomyelia. Joffroy and Achard have recorded a case with well-marked symptoms of Morvan’s disease, in which the characteristic lesions of syringomyelia were found after death. Galloway and Lindsey Scott (b), the English translators of Bruhl’s paper, state that their author, although he makes the reservation that we are not justified in regarding all cases of Morvan’s disease as cases of syringomyelia, leans to the opinion that the two conditions are expressions of similar pathological lesions.

The symptoms of syringomyelia, although they vary somewhat, according to the lateral extent

of the cavity, are fairly characteristic. We have progressive muscular atrophy with paralysis affecting one or all of the muscles of one arm, and possibly later involving the corresponding group of the opposite extremity. Then there are vasomotor and trophic disturbances, including localised hyperaemia or anaemia of the skin, serous exudation with desquamation, and even patches of gangrene. In the majority of cases these symptoms occur spontaneously, that is, without any apparent cause, but sometimes they follow injuries. Another characteristic symptom is the loss of sensation of pain and temperature in the atrophied parts, which is well marked and permanent, as in Charcot's condition called by Charcot "dissociated anaesthesia." The existence of any one of these symptoms would be suggestive of syringomyelia, whilst the combination of any of them renders the diagnosis fairly certain. All cases of slowly advancing muscular atrophy attended with neuralgic pains suggest the possibility of glossis spinalis, and should be studied with reference to the pain and temperature sense.

There is, I think, but little doubt that a condition closely allied to Morvan's disease may be an early manifestation of syringomyelia. The following is a case in point:—A needlewoman, aged 50, was admitted to the Westminster Hospital on March 23, 1903, and again in May of the same year. Her story was that nine years ago her left hand suddenly became swollen, and soon after contracted, and the muscles wasted. There was loss of feeling in the tips of the fingers, so that she was unable to follow her occupation. Three years later a similar change took place in the right hand, accompanied by swelling and severe pain in the wrist. It was not clear that she suffered from whitlow, but she speaks of bruises which appeared on the arms without apparent cause. She had not noticed any abrasion of the skin, but on examination it was found that there were on the index and middle fingers of the left hand two deep cracks, extending nearly half-way round the fingers, a similar crack almost healed being noticed on the index finger of the left hand. The other symptoms need not be described in detail, but it may be mentioned that there was well-marked wasting of all the muscles of the left shoulder-girdle, arm and hand. The left shoulder-joint presented a good example of glosmatous arthritis. Tactile sensation was deficient in the left arm, and in this region the patient was unable to distinguish between heat and cold. It was noticed that the greater the difference of the temperature of the test tubes employed the greater was the difficulty of the patient in arriving at a correct conclusion. The tube first applied was described as "cold" and the next as "colder" even when water at a high temperature was employed.

This was undoubtedly a case of syringomyelia, but at its onset it might, even in the absence of whitlows, have been mistaken for Morvan's disease. It is clear, too, that both Morvan's disease, and syringomyelia, might readily be mistaken for rheumatism, the pains of the former for muscular rheumatism, and the gliomatous arthritis of the latter for articular rheumatism.

The appointment of Dr. C. J. Martin as director of the Lister Institute of Preventive Medicine makes vacant the chair of Physiology at the University of Melbourne.

MIDWIFERY AS A BRANCH OF THE MEDICAL PROFESSION. (a)

The lecturer alluded to the supreme importance of antisepsis and asepsis in the practice of the science and art of obstetrics, remarking upon the great diminution in the mortality of lying-in women since the introduction of Listerian methods. This was especially noticeable among women in which class it was often difficult to ensure that their surroundings were in accordance with modern principles in this respect. He pointed out that it was advisable in all cases that the general practitioner should make the choice of the nurse himself, and several instances were narrated in which, though every antiseptic precaution had not yet been adopted, the patient's puerperal fever simply owing to the fact that the nurse had been in previous contact with a case of that description. For his own part he took care to employ none but a fully certificated nurse who could be relied upon in small details. If anything did go wrong, it was the medical man who was held responsible, and not the nurse.

The importance of manual examination of the abdomen of pregnant women was strongly emphasised, the value of which was not far behind the discovery of antiseptics. To be effective this should be performed in all cases, certainly in the ninth month, but better still towards the end of the eighth. The relationship between the size of the child and the swelling of the pelvic organs is shown excellently by this means, and frequently afforded greater information than internal pelvimetry, which, besides being rather a painful process to the patient, was really of little use except immediately after the conclusion of labour. Moreover, false positions of the child could be more easily rectified before the commencement of internal version, under certain circumstances, and this applied more especially to the latter months of pregnancy. It was a good plan to get patients to measure themselves with a tape round the abdomen in successive weeks towards the end of pregnancy and report the measurement to the doctor, and if this should be over thirty-six inches, a more detailed physical examination could then be made. Though it was true that high degrees of obesity might interfere with the accuracy of the results, yet it would be found that exceedingly fat women did not so often become pregnant.

The necessity for making as few vaginal examinations as possible when labour had actually commenced was also alluded to, according to the wise advice of Lister. In "conducting" a labour, the safest plan was to remember throughout that it was the duty of the accoucheur to work with Nature, and the neglect of this general principle, particularly when instrumental aid was required, would be found to be fatal to true success. But the dangers of labour were not onl mechanical. There was the dreaded complication of haemorrhage, the occurrence of which the medical practitioner was often as powerless to explain as to prevent. It was another matter, however, with
haemorrhage coming on after labour, and this was generally preventible. Here, again, Nature must be given time, and the best results were often to be obtained, not by "following down" the uterus with the hand to the abdomen, but by allowing the placenta to come out naturally into the vagina. The older method of expression was especially to be condemned as apt to lead to troublesome, or even serious, secondary haemorrhage.

In discussing the measures more directly applicable to the child, it was pointed out that Credé's prophylactic against ophthalmia neonatorum succeeded wherever it had been tried. A little tact was needed in its adoption among the upper classes, but any prejudice against its use could soon be overcome by a judicious demonstration of its obvious advantages. A solution of 1 in 1,000 of the perchloride of mercury should find a place in every lying-in room.

Although there was little that was novel in his remarks, the lecturer wondered that the text-books did not lay more stress upon them than they did. It had been stated, somewhat reproachfully, that the accoucheur was responsible for a large proportion of the cases that found their way to the gynaecologist, but if these were true in the past he felt sure that it would not be so in the future.

French Clinical Lectures.

RETRACTION OF BANDL'S RING AS A CAUSE OF DYSTOICIA.

By R. DE BOVIS, M.D.,
Professor at the School of Medicine of Reims.

[Specially Translated for the Medical Press and Circular.]

BANDL'S ring, Schroeder's "contraction ring," Baudelocque's "uterine ring," Lust's "retraction ring," &c., is the circular muscular zone which completes the lower end of the upper segment of the uterus. On section of the uterine wall, nothing, or very little, reveals its existence; between the thin muscular layers of the upper segment and the very thin one of the lower one the transition is abrupt; but at the limit of the first of these segments there is to be seen neither a prominence nor a furrow which would indicate to the naked eye the existence of any special muscular band. Macroscopically, therefore, its existence is merely conventional, or very nearly so. From a histological point of view, this is not quite the case. According to M. J. Veit, some circular muscular fibres assist in its formation in greater number than in any other part of the body of the uterus. In a pregnant woman, but not actually in labour, the uterine band is almost on a level with the brim, though rather below than above, but as soon as labour begins, the uterine band, dragged upon by the contractions of the upper segment, ascends to some extent. With strong contractions it may be found half-way between the umbilicus and the pubis. If the pains be very severe it may even rise to the level of the umbilicus.

In virtue of its muscular structure, Bandl's ring forms a contractile ring or ligament, in the uterine cavity must pass. Under various conditions this narrow channel may contract still further, and even become tetanised to such an extent as to arrest the onward progress of the fetus, in which event it constitutes a cause of "dystocia," by contraction of Bandl's ring. This variety of dystocia may occur in any presentation. Out of 36 complications of this kind in cases of simple pregnancy, M. Chéron observed 35 vertex presentations (62.5 per cent.), 12 shoulder presentations (21.4 per cent.), 4 face presentations (7.1 per cent.), and 5 breech presentations (8.9 per cent.).

We should, however, form a very wrong idea of the predilection which this dystocia had for particular presentations if we relied on the above averages. They do not take into account the relative frequency of the various presentations. For instance, vertex presentations occur seven times as frequently as those of the breech, and we must not forget that there are usually twenty-five to thirty vertex presentations for one breech.

If, on the contrary, we compare the relative frequency of the presentations with M. Chéron's figures, we shall see that in vertex presentations retraction of Bandl's ring happens twice less frequently than it ought to normal if this complication bore equally on all presentations. On the other hand, breech presentations it recurs 35 times; on face presentations 35 times; and on shoulder presentations 71 times often than it would if the natural frequency of presentations obtained. Putting vertex presentations on one side, this complication is most rarely observed with breech presentation.

Unfortunately, the figures given above do not tell us in what proportion of cases retraction will occur in a given number of presentations. All I can say on the subject is that out of a hundred breech presentations I only met with it once. We must, therefore, not be surprised that the list of observations published is still so scanty.

The case in question may be regarded as a typical instance of dystocia caused by retraction of Bandl's ring in breech presentation. I was called one evening to attend a woman, aged 38, strong and rather obese, who had been in labour for twenty-four hours. The waters had broken the night before. During the day, as labour did not progress, a medical man had endeavoured to bring down a foot, and finally applied the forceps without success.

We had to decide the cause of the arrest of labour. The mother, who was at term with her fourth pregnancy, and whose previous confinements had been normal, had no tumour nor contraction, nor, in fact, anything abnormal. The pains and the contractions of the uterine walls appeared to have been, and were still, of sufficient intensity to exclude the idea of uterine inertia. Palpation revealed neither furrow nor strangulation to explain the arrest of delivery, but it is only right to add that the patient's obesity was an obstacle to thorough exploration.

At the suggestion of the operators to form a clearer idea of the situation, I had the woman anaesthetised, and I forced my hand into the lower segment of the uterus. The fetus was in the sacro-ilac left anterior position, the breech presenting. This was partially engaged in the brim, and I found no trace of any tumour. On my examination, I tried to penetrate into the superior segment, following the posterior wall—that is to say, the thighs of the fetus. But having reached the popliteal space (of the fetus), about half-way up the uterus, I was stopped by a circular projection of the posterior uterine wall, forming a ridge, which pressed closely upon the thighs of the fetus, and which firmly resisted any further progress of the hand, and even of the fingers. The free edge of this prominence was thin and sharp; its resistance was very great; in fact, it felt like cartilage, as in a case recorded by Th. Smith. After having changed hands five or six times, I was able to reach beyond this ridge with the last joints of the index and middle fingers of my right hand. Above it, the wall of the uterus did not seem to be in contact with the fetus, for I could feel between this sharp edge of the ring and the wall a kind of gutter about half an inch wide. I could not, however, say that the fundus was relaxed; indeed, the contrary would be nearer the truth.

These manipulations, which were very laborious, but were carried out without undue violence, had ultimately the result of bringing about a slight abduction of the right thigh, so that I was able to bring down the corresponding foot in the channel or gutter which existed in the further side of the ring. The last
joints of my fingers then reached the heel, but could not grasp it. With the tips of my fingers I pushed this heel forward along the upper edge of the ring. Having reached the antero-lateral region of the uterus, I again confirmed that I could grasp this heel and pull it down into the lower segment. This was rendered possible by the fact that the neck of the Bandl's ring, in this case, diminished in prominence progressively from behind forwards to such an extent that at the back of the fetus it was reduced to little or nothing. The foot which was brought down (the posterior right foot) was, of course, the wrong foot, but in such a dilemma one brings down the foot that happens to be nearest to the hand. It would have been absurd to pass another fifteen or twenty minutes trying to get hold of the right (good) foot, at the risk of increasing the chances of infection of the patient. To complete the extraction of the child, I had only to make the breech undergo a rotation of three-quarters of a circle, which changed the lower foot into the right (good) foot, and then to pull in the axis of the pelvis channel. This I effected without any particular difficulty. The child was a female, and weighed 4,400 grammes, but it could not be resuscitated.

It will be seen that Bandl's ring encircled the fetus, and yet barely engaged in the cavity of the pelvis, on a level with the thighs quite close to the popliteal space. That is the most typical variety in respect of the relationship of the fetus to the retraction ring. Among this first class of facts, one may place the case observed by Hahl and Bindeau, this position of the ring was as in the one just related, barely engaged, but Bandl's ring was much higher and pressed upon the neck and the upturned legs of the fetus, so that the cavity of the uterus contained nothing but the legs and the head of the fetus.

In a second variety the whole of the fetus is placed above the ring. In this connection I may refer to the cases of Miss Bow, Hahl, Rossa, Brinob, and Meurer. Sometimes, as was the case in a patient of M. Rossa's and one of M. Meurer's, there is a protrusion of one or other of the lower limbs through the uterine ring. Hahl's and Bindeau's cases deserve separate mention. In the first the fetus, under the influence of uterine contraction, was subjected to such pressure or huddling altogether that the practitioner, having at first made out the breech in the annular orifice, ultimately decided to get the head there. The examination also revealed a breech presentation to begin with, but, thanks doubtless to a less degree of contraction of the uterine fundus, it was promptly converted into a shoulder presentation. Hahl's case is described in detail by Crim, whose description, according to M. Smith, is rather obscure. Here, too, there was, to begin with, a breech presentation, but at each contraction the head could be felt coming further down into the pelvis.

Lastly, in the third variety the retraction only takes place at the passage of the head last, and Bandl's ring then contracts round the neck of the fetus.

The majority of these retractions happened in cases of incomplete breech presentations, the lower limbs being drawn up on the anterior surface of the fetus. The diagnosis is easy with the hand inside the uterus. This might be possible before birth, since, when Bandl's ring contracts, the uterus assumes the shape of a pumpkin. This is the form described as "hour-glass" contraction by Tacquemier, as also by English and American authors. This shape is most frequently met with in cases of vertex, face, and trunk presentations. It is, however, often absent in the breech presentations. Out of the fifteen observations that we have collected, this deformity was only noted in one. In one case, on the contrary, it was characterised by a peculiar feature. "On the right edge of the uterus was to be seen a tumour which reached from the inguinal region to the umbilicus and merged into the uterus. As the abdominal wall was very thin, one could see through it very clearly that this tumour was formed by greatly dilated veins." These veins were probably those of the psmoinformplexus, the fetus being in the sacro-ilac right posterior position.

M. Meurer thinks that this dilatation was probably caused by pressure on the veins by the breech, especially during uterine contraction.

There are several reasons to explain the rare occurrence of "hour-glass" contraction. As we have seen, the ring may occupy various positions in relation to the fetus. When it compresses the trunk and the popliteal spaces, the trunk and the flexed thighs form too big a mass for the ring of contraction to be able to become very narrow, hence its existence may not be perceptible in the body of the uterus. If the ring is situated below the fetus, or encircles its neck when the head becomes engaged, the mass which is thus caused is so close to the pelvis that it may easily escape notice. It is true that careful palpation, when the fetus is caught round the waist, ought to reveal a furrow or a dent; but, unfortunately in breech presentations the fetus usually has the back in front; and as we have shown, the annular prominence is always little marked opposite the back of the fetus.

Another reason which tends to prevent these indications being perceived is, according to Turenne, that women with contraction of the uterine band are frequently, or at any rate fairly stout. This, indeed, was the case with my patient, although in Meurer's case the abdominal wall was not unusually thick.

We have not mentioned along with the symptoms—and it cannot be taken into account in the diagnosis—the intense pain suffered by parturient women presenting this retraction of Bandl's ring; indeed, this Kummers's present pain is probably more often due to a general tetanisation of the uterus than to contraction of the ring: besides, pain as a symptom has such a subjective value, and is so variable, that we must not attach much importance to it.

To understand the source of this retraction of Bandl's ring we have only to invoke the physiological function of this muscular band. Although the physiological function of the uterus is far from being elucidated, it may be well to sketch its main features as we understand it.

As with all muscles the longitudinal fibres of the uterus, to act effectually, must have a fixed, or tolerably fixed, insertion. It is not on the fundus or the sides of the uterus that they can get this grip. It follows that the only "pull" must be exerted on the upper segment, that is to say, on the second vagina. This is precisely what the longitudinal fibres of the upper segment, thom the comparatively fixed insertion which they require in order to act upon the fundus and the lateral walls of the uterus. As for the ring itself, it attaches itself to the lower segment, passing through it to the vagina and to the fibrous structures of the true pelvis.

On account of the marked elasticity of the lower segment, Bandl's ring is, we must admit, only a relatively fixed insertion, being itself capable of being drawn away by the fibres of the fundus. But for that very reason this is an advantage; the lower segment thus becomes stretched or dilated, and it, so to speak, tugs at the presentation and envelops it.

It may be objected that the contraction of Bandl's ring, though it provides the required fulcrum, would have the drawback of opposing the progress of the fetus. This argument, however, loses much of its force if we take into account the enormous muscular mass of the uterine fundus compared with the very small one of the zone of Bandl. Besides, as mentioned by M. Rossa, the muscular fibres of the upper segment, which are on the uterine band, are not in a vertical direction; thanks to the pear shape of the uterus, they leave Bandl's region in an upward and outward direction. The effect of their contraction, then, is to neutralise the physiological compression of the ring. Besides, as suggested by M. Keiffer, on the strength of his experimental researches, the circular fibres of the uterus have a "sphincter" action on the progress of the fetus. If the contraction of these fibres of the body do, under certain circumstances, resist the progress of the alimentary mass, faces, &c., they also.

favour their expulsion, or, strictly speaking, their "expulsion," as soon as the greatest diameter of the 
may pass.

Lastly, the zone of Bandl plays the part of a "gutter": it moulds and kneads, so to speak, the fetus in its longitudinal axis, and it favours the effects of the contractions of the dome of the uterus, which, on the contrary, have for effect to compress the fetus in the opposite direction, and to bring the cephalic and pelvic poles together within the true pelvis. M. Kerbhr notes that in order to explain these observations, denies any specific action on the part of Bandl's ring. He holds that its contraction "is nothing but an ordinary motor reaction, which may occur either close to or outside the uterine or its edges." As far as experimental events, we do not contest the fact; it is even possible that careful clinical observation may, in time, enable us to establish the fact that the contraction ring does not always, and necessarily, occupy the zone of Bandl. Under certain circumstances, at any rate—either by clinical observations or during operations or post-mortem—we have been enabled to ascertain for certain that the retractions referred to always occupy approximately the same anatomical region of the uterus—viz., that of Bandl's zone, and until further information be available we are justified in following these data.

This, in our opinion, is the physiological function of Bandl's ring. If this ring be, for one reason or another, now subjected to excessive strain, we shall see it attain every degree of contraction, from simple spasm to tetanus.

This division, established on a simple a priori physiological basis, seems to be confirmed by facts. In the case recorded by Brindeau, for instance, the hand easily overcame the retraction.

The causes of this tetanisation or spasm must evidently be frequent and too fast in the contraction of Bandl's ring, probably coinciding with that of the uterine body. Consequently, all the agents likely to bring on violent iterative contraction of the superior segment may occasion retraction of Bandl's ring. In vertex presentations, for instance, this variety of dystocia is most often met with in cases of narrow pelvis.

Therefore, it is not a matter of chance that in breech presentations it has so far almost always occurred with the buttocks presenting, indeed, thedouble-up of the lower limbs markedly reduces the small degree of flexibilite of the breech, the fetal mass adapting itself to the curve of the pelvis only with the greatest difficulty. The first effort of the latter results in the contraction of the uterus, which necessarily bears on Bandl's ring. It is worthy of note that out of fourteen observations in which this detail is mentioned, five referred to multipara (having been pregnant four times or more), eight to young primipara (the eldest of whom was 26 years of age), and one a secundipara. It is, therefore, in connection with the two extremes, from an obstetrical point of view, and above all with primiparity, that we are the most liable to meet with this particular form of dystocia. The reason for this is very simple—in the young primipara the uterine muscle is stronger, but the pelvi-perineal tissues are much more resistant. In multipara the two tissues allow us to grasp the latter more easily. But it is possible that M. Turenne's remark concerning obesity may be a corollary of the latter, multiparity and obesity often going together.

In conclusion of Bandl, in spite of the apparent hypertrophy of the uterus, this organ is in reality poorer in muscular fibres, the abdominal wall is more dilated, the children are larger, all of which circumstances render accommodation and expulsion more arduous. It is possible that M. Turenne's remark concerning obesity may be a corollary of the latter, multiparity and obesity often going together.

Concerning the stage of pregnancy, there are, out of the fifteen cases referred to, two cases (Phillip's and Rossa's) of premature delivery, one at six and a half months, the other at five months. M. Kerbhr's as a rule to explain these observations, states that in cases of prematurity of the uterus, due to retraction of Bandl's ring, has been obse
proposed. But when the child is alive, the traction must be very gentle if we wish to avoid lacerating the tissues as in Smith's case.

Moreover, even if we succeed in getting a good grip of the fetus, traction should be very gentle, otherwise the uterus, instead of the fetus, may be pulled down. In Hahl's case, for instance, the resistance of the ring was so great that the uterus came down to such an extent that the cervix appeared at the vulva.

If retraction only takes place or only becomes troublesome when the head is passing last, we may be obliged, if traction prove inadequate, and if a retroflexion of the head has not subverted the contraction of the ring, to make use of the forceps. But as this application may entail considerable difficulty, and as the child will in any case soon succumb, we should be justified in decapitating the fetus, then having recourse to cæphalotripsy.

Gentle means may all fail. Must we in such cases employ more violent means, or have recourse to surgical intervention? The former, as we have already seen, can never be justifiable; forced dilatation and incision (Hahl) entail great risk. It would be better in such a case, as was done by M. Treub, in a vertex presentation, to have recourse to Cæsarian section. Before having resorted to this extreme measure, however, it would be prudent to temporise, trying what we can do with narcosis pushed as far as possible.

It may be objected that temporisation, with the uterus, or at any rate Bandl's ring, tetanised, may lead to rupture. This danger is perhaps less imminent than we imagine. Tetanisation is the contrary of contraction. The tetanised muscle is hard, painful, more or less retracted, but has lost its contractility. It consequently no longer drags upon the lower segment. The latter is much stretched—dilated, it may be, to the utmost—but the uterine muscle and the zone of Bandl no longer inflict violent, sudden, irregular shocks, which are the real cause of rupture. In any case surgical experience does not seem to condemn this course, with the exception of Lewis' cases, in which dilatation was obtained by force. It is worthy of notice that uterine rupture has never happened in any of the fifteen cases that we have collected.

It is true that temporisation may not prove injurious to the mother, but it is almost certain to kill the child. This danger has been effectually notified, in the shortest possible time the foetal mortality was enormous. Out of fourteen observations—doubling one miscarriage—the child would only be brought out alive in four; and even so, in two of these, at any rate, there seems to have been much more spasm than tetanisation.

When the child dies, mutilating operations become justifiable, but even then these operations are far from easy; indeed, the child has to be brought out piece by piece.

If the child be alive, and if we hope and desire to get it alive, the probable operation is unquestionably Cæsarian section. Nevertheless it is to be apprehended that recourse thereto almost of necessity entails the sacrifice of the mother. Women who present retraction of Bandl's ring generally fall into the category of the infected. The waters have usually broken long since, and several medical men have examined and handled the patient several times over, and in infected women, the results of Cæsarian section are anything but brilliant.

Clinical Records.

ROYAL FREE HOSPITAL.

Carcinoma of the Sigmoid Flexure.—Resection of Intestines.—No Recurrence after 3½ years.

Under the care of Mr. James Berry, F.R.C.S., Surgeon to the Hospital.

E. S., aged 35, was admitted into the hospital on March 2d, 1900, with intestinal obstruction of five days' duration. She gave a history that for some six years she had suffered more or less from circumvaginal and anal increase in the size of her abdomen. For three years she had noticed at times a blood-stained discharge from the rectum, and she had also had a good deal of dull pain in the lower part of the back. The bowels had last been opened on February 25th, and since February 27th she had vomited several times, and had had a certain amount of pain across the lower abdomen.

The patient's general condition was: She looked healthy and had a good colour. Respiratory and circulatory organs presented no abnormality. Pulse was 100, small and regular. Temperature 9°. Examination of the abdomen showed it to be uniformly and considerably distended. It was everywhere resonant, and not particularly tender. Nothing abnormal could be detected except the distention. Rectal examination revealed nothing but a soft and freely movable tumour containing small intestines, filling up Douglas's pouch. A diagnosis of acute obstruction following chronic obstruction was made, due probably to new growth of the upper part of the rectum or sigmoid flexure. On March 2d an inguinal colostomy was performed. Through the wound there escaped a thin blood-stained fluid. In its neighbourhood the peritoneum was inflamed. The sigmoid flexure was distended and injected, and the thickness of its wall increased. Just below the brim of the pelvis there was a swelling in the bowel about the size of a Tangerine orange, which was hard, and freely movable. The bowel containing this tumour could not, however, be drawn into the wound, owing to its being fixed by its short mesentery. The upper part of the sigmoid was fixed to the abdominal wall with sutures. The intestines were opened just as then, as the symptoms of obstruction were not severe, so the wound was covered with protective, over which sterilised gauze was applied. On the three days following the operation the patient passed a nutrient enema of beef tea and peptonised milk of each two ounces every four hours, in addition to which she was allowed hot water, peptonised milk, and tea for the mouth. She vomited on March 3rd, and again on March 5th, but the vomit was clear and brown, and generally mixed with some mucus, but it was never faecal. On March 8th the bowel was opened, and a Paul's tube inserted, through which faeces escaped. The tube was corked and the wound covered with sterilised gauze. The patient felt very much better after this, and was able to enjoy her food, and the vomiting ceased. The wound was dressed every three hours, in the tube was left in for two days, and removed on the 7th; the distension of the abdomen had then considerably diminished, and so on the following day the patient was put on light diet. The bowel acted through the artificial anus. On the 14th the upper portion of the loop of intestine, which protruded through the incision in the abdominal wall, was cut away, leaving about three-quarters of an inch above the skin. On March 22d, water was syringed through the lower of these two openings, but it all returned the same way; none passed on and escaped by the anus. The growth could be distinctly felt on exploring the intestine through this inferior aperture. Regular action of the bowels was secured by castor oil and mistura alba, and the lower part of the bowel was syringed daily through the anus.

On March 24th, a second operation for the removal of the growth was undertaken. The colostomy wound was well dressed so as to prevent contamination of the new incision, which was made in the median line, through the linea alba, extending from a point situated one inch below the umbilicus for three inches. The fascia and pyramidalis were divided, and the peritoneal cavity opened. The sigmoid flexure and the growth were drawn up into the wound, and it was found that there was only separation of the two walls of the bowel in the colostomy wound by two inches and a half of intestine. The bowel was clamped on each side of the growth, and after packing off the abdominal cavity, four inches of the intestine were removed, and the mesentery was cut. The divided ends of the colon were then sponged with hyd. perchlor. 1 in 2,000, and each end sewn up by sutures passing through the whole thickness of its wall. As the bowel
was somewhat inflamed and the stitches showed a tendency to tear through, a second continuous suture was made, passing only through the peritoneal and muscular coats. A small, hard gland was also removed from the mesentery. After cleaning the wound and the bowel were united by a continuous silk suture, then the subcutaneous tissue and finally the skin. A wick of sterilised gauze was left in the lower angle of the wound to act as a drain. Indiarubber tubes were put into the rectum and into the lower opening of the bowel in the colotomy wound to prevent distension with flatus. The wound was then dressed with collodion and gauze to prevent infection from the artificial anus. The gauze drain was removed the day following the operation. There was still a good deal of discharge from the rectal tube. The temperature rose to 100°, and the pulse to 120, but these rapidly subsided to normal. The patient, whose diet consisted of fluids, was fed every hour.

Nine days after the operation, on April 2nd, the stitches were removed, the edges had united, and the wound looked healthy, but there still was a fair amount of discharge from the rectal tube and the one inserted into the lower opening in the abdominal wall; that from the latter was yellowish and semi-purulent, with a bad offensive smell; from the anus it consisted mainly of mucus. These tubes were taken out daily and shortened as required. The tube in the colotomy wound was left out on April 17th, and on the following day the patient was able to get out of bed. From this time the colotomy wound had healed and the general condition continued improving; but on the 19th a small stitch abscess formed round the middle part of the wound. This was opened, and half a drachm of blood-stained fluid escaped. It was lightly plugged and covered with collodion and gauze. The dressing was renewed every day, and the wound healed almost completely, so that when she was discharged on May 11th, one small dressing of granulation was left.

On August 29th she came up complaining of pain and of the passage of blood, slime and fæcal matter per anum.

An artificial anus was perfectly healthy. The lower opening led into a cul de sac about an inch and a half in length, from which a small mass of impregnated mucus was removed; a similar mass was removed from the rectum through the anus.

In July, 1900, she was readmitted on account of diarrhœa and sickness, from which she was suffering. Her abdomen was distended, and there was an offensive discharge from the left side of the lower abdominal quadrants.

On examination, a hard tender lump was felt on the lower side of the colotomy wound, from which pus was discharged, due to a stitch abscess in the abdominal muscles. It was fomented, and got rapidly well, so that on September 14th she was discharged. She reports herself from time to time, and on the last occasion, July 16th, 1902, the rectum was examined and nothing abnormal was felt. No secondary growths were felt in the abdomen.

Description of Tumour (now in the Royal Free Hospital Museum).—The piece of bowel removed was four inches long. The lower three inches were infiltrated with the growth, which projected from the lower end as a cauliflower-like mass. It had completely blocked the lumen of the gut. Microscopical examination showed adenoid carcinoma.

Remarks.—The general and uniform distention of the abdomen, the long duration of the constipation, and the slightness of the vomiting all pointed to an obstruction low down in the large intestine. The history of the passage of blood and slime from the rectum indicated an ulcerated surface. The age of the patient suggested a malignant tumour as the most probable cause of obstruction. It was obvious that an immediate colotomy afforded the only means of saving the patient's life. The examination of the growth that was made through the colotomy wound showed that the tumour was freely movable and fairly accessible. As the patient was in good condition and not very old, it seemed reasonable to make the attempt to eradicate the disease by an extensive resection operation.

What there has been no recurrence after more than three years, and that the patient is now in excellent health, is no doubt due to the fact that adenocarcinoma of the large intestine is often a tumour of a low degree of malignancy. It usually grows slowly and has less tendency to disseminate than many other forms of malignant growth. Its occurrence in a comparatively isolated part like the sigmoid flexure permits also of a more thorough and satisfactory removal of the disease.

BRITISH SANATORIA FOR CONSUMPTION.—XV.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE FORSTER GREEN HOSPITAL, FORTREDA BELFAST.

The Forster Green Hospital for Consumption and Chest Diseases is the outcome of the liberality of Mr. Forster Green, a Belfast merchant. The institution is situated on the Castlereagh Hills at Fortreda overlooking Belfast, and can be readily reached by tram and a ten minutes' walk. It stands in forty acres of well-wooded grounds. The building was originally an old country house, but the rooms have, as they would allow, been adapted for their present purpose. Unfortunately, much good money was originally wasted in efforts to ventilate the rooms according to the plenum system, which, needless to say, proved very unsatisfactory, and has, of course, been discarded.

At the present time the hospital is conducted in accordance with open-air principles. A long veranda runs for seventy feet along the north-west side of the house, but is rather unnecessarily deep, somewhat darkening the rooms behind. There is accommodation for thirty-eight cases, four beds being kept on the verandah, and those who are fortunate enough to secure a place here are said always to do best and improve the most rapidly. The greater part of the verandah is, however, used only as a resting shelter.

The hospital is intended for the poor, some of the beds being quite free, but generally, 12s. 6d., 19s. 6d., and 26s. 8d. are charged respectively, in addition to the usual small contribution towards cost of maintenance is expected from the friends of the patients, varying from two to fifteen shillings a week. Cases are recommended by subscribers. The hospital is governed by a Board of Governors and a Committee of Management. Dr. R. J. Purdon, Dr. Simpson, and Dr. F. Howard Sinclair are the honorary physicians. We consider it a serious drawback that there is no resident medical officer, although the general care of the patients is apparently admirably directed by the capable matron, Miss M. E. Wright. If the best results are to be obtained by the hygienic treatment of consumption, cases must be kept under constant medical supervision, and it is a remarkable circumstance that the committee of management should have overlooked this all-important point.

In connection with the hospital there is an out-patient department at 46 Upper Queen Street, Belfast, where poor persons are seen on Mondays, Wednesdays and Fridays from 11 a.m. to noon, and except in cases of extreme poverty a fee of one shilling is charged. In-patients are admitted in rotation after their case has been examined and approved of by one of the physicians. The hospital is deserving of increased support. The grounds surrounding the main building afford ample opportunity for much-needed exercise, and the adjoining bungalows could well be erected in some of the many convenient sheltered situations. More day shelters might be erected with advantage. A new dining-room should be provided at once.

Pulmonary tuberculosis is exceedingly prevalent in Belfast and district, and it would be well if means were immediately secured whereby the excellent work
now being carried on by the Forster Green Hospital under considerable difficulties could be considerably amplified.

After a thorough inspection of the hospital and a careful study of the annual report we are of opinion that while satisfactory results have been obtained with certainly limited opportunities, by a wisely directed extension and the appointment of a suitably qualified medical man the usefulness of the institution might be very greatly increased. A copy of the annual report may be obtained by applying to Mr. Alex. A. Shaw, the hon. secretary, at 2 May Street, Belfast.

Transactions of Societies.

Clinical Society of London.

Meeting held Friday, October 9th, 1903.

Dr. Frederick Taylor, F.R.C.P., President, in the Chair.

Sir Dyce Duckworth on a case of erosive gastric ulceration, with severe haematemeses, operation, recovery.

E. W., aged 29, a book sticher, was admitted to St. Bartholomew's Hospital on November 21st, 1902, suffering from repeated attacks of haematemesis. Pain had been felt after taking food for three weeks before admission, lasting about an hour, unaccompanied with vomiting. He had been treated eighteen months previously for "indigestion," with pain, but no vomiting or pyrosis. Several attacks of bleeding had occurred for the first time on the day of admission. The patient was blanched, the belly distended, and the epigastric region tender on gentle pressure. Treatment consisted in rectal feeding, and small doses of adrenaline chloride, by the mouth, in teaspoons of water. A dark motion was passed on November 22nd. Subsequently whey, in two ounce quantities, was given by the mouth, then in four ounce doses. A pint of saline solution was also daily injected into the bowel. On November 30th, the pulse rose in frequency, and there was headache. The pallor increased. Dark motions were passed.

On December 3rd she vomited twelve ounces of blood and watery fluid, bright red in colour. Two hours later ten ounces of the same material was vomited. There was clear evidence of active and continuous gastric haemorrhage, and Mr. Langton and Mr. Butlin, who now saw the patient in consultation, agreed that it was advisable to operate at once and deal with the source of the bleeding. Mr. Duckworth took over the patient, and with Mr. Lockwood's assistance he opened the abdomen on December 4th, and made an incision in the anterior wall in the long axis of the stomach. Nothing that could be called an ulcer was found on examining the interior of the organ, but in the greater curvature near the pylorus the mucous membrane over several square inches was found pink and markedly different from the rest of the membrane, which was of an ivory yellow tinge. At various points on this pink area were found slight excoriations, fissures, and tiny points, from which blood slowly oozed. Mr. Lockwood ligatured a number of these points with fine silk thread with a purse-string suture, and the opening in the stomach was closed by a continuous silk suture which embraced all three coats. The abdominal wall was closed by three layers of continuous silk sutures, the ends of which were left out at each end of the wound. The operation lasted three-quarters of an hour, and was well borne, not more than a drachm of blood being lost. Some vomiting followed the operation. On December 5th the temperature fell from 101° to 95°. Three ounces of blood were vomited this day, and no blood. Feeding was carried on by the bowel, while saline solution, one pint, with a drachm of liq. calcis seccharatii in it, was also administered by the rectum. By January 8th the patient was taking boiled fish, and on the 14th mince meat. By February 4th, she was well, and sent to the Convalescent Home at Swanley. The condition of the gastric mucous surface discovered here is believed by Dr. F. J. Smith and Mr. Mansell Moulin to be the starting-point of most, if not all, gastric ulcers, and it is probable that if the haemorrhages dependent on it proved fatal in any instance the actual lesions would not be detectable after death.

Mr. Mansell Moulin referred to the case which he had read before the Society three years ago on this subject. He had operated in eleven cases of erosive ulcer and he discussed the differences in the appearances of the mucous membrane during life and after death. He urged that operation in these cases should be undertaken before the patient had become too exhausted. It had been stated that haematemesis was only fatal in 3 per cent. of the cases of gastric ulceration he had operated, but he pointed out that no one had ever proposed to operate in every case of a gastric ulcer. Only about 10 per cent. of the cases were really serious, and these alone concerned the surgeon. The indication for operation was the occurrence of repeated severe haemorrhages, especially if associated with intense anaemia.

Dr. F. de Haviland Hall agreed as to the indications for operation, but demurred to the statement that 10 per cent. of the cases were serious, adding that in nine years at the Westminster Hospital, although he had seen many cases of gastric ulcer, not one of them had proved fatal, and in only one instance had he supervised operation.

Mr. Barker advocated the operation of gastro-duodenotomy, which not only tended to bring about cessation of the bleeding, but also gave the stomach space and its muscular action.

Mr. Wallis commented on the difficulty of making out the situation of the ulcer from external examination of the stomach, and he advocated making an incision into the organ for that purpose forthwith, since this enabled the surgeon to ascertain the bleeding spot without unnecessary delay.

Dr. Louis Pasteur discussed the differential diagnosis of haematemesis from cirrhosis, and that due to gastric ulceration, which, he thought, often presented very great difficulty.

Mr. Keetley observed that it operation for gastric haemorrhage was to develop as some surgeons desired, and as the operation for perforation had done, a very different procedure would have to be followed. The practice of cutting down to find the bleeding spot might be all very well when every possible facility was available, but it was hardly practicable in general surgery. In a more severe case of his own he experienced considerable difficulty in locating the bleeding spot, although he had opened the stomach pretty freely. He ultimately found that the ulcer was adherent to the diaphragm and produced also to the pancreas, and he pointed out that he would not have been very different to the perforated ulcer. He had separated the adhesions and packed the cavity and the patient recovered, though she subsequently had to undergo gastro-enterostomy, an operation which he held in great esteem.

Mr. Butlin remarked on the fact that while some surgeons had never seen haemorrhage recur the result probably depended partly on the man, and after gastro-enterostomy others had met with it often, and suggested that it depended partly on the ulcer. In such cases he thought the best plan was to open the stomach. If they could find the bleeding spot they could deal with it, and if not they might do gastro-enterostomy.

Sir Dyce Duckworth, in reply, discussing the etiological factors, remarked on the frequent association of gastric ulceration with intense anaemia, and he pointed out that this lesion was met with in the better classes, who had good food, while common in hospital patients.

Mr. Anthony Bowley on a case of acute haemorrhagic pancreatitis.

The patient was a man, aged 41, who was seized with severe abdominal pain and vomited the November 12th, 1902. During the next two days there was some complaint of flatulence and constipation, and the vomiting continued. The abdomen was tender, but no swelling could be felt. The bowels acted well to emunctura.
On the third day of the illness the patient became delirious, and from that time onwards suffered from delusions. The urine was very greatly diminished in quantity. On the eighth day after the illness commenced there was a sudden attack of pain with severe vomiting and profuse sweat, great distension of the abdomen and complete obstruction. For the relief of this the abdomen was opened and there was found to be some general early peritonitis, with old adhesions, but no mechanical obstruction of the bowel. A collection of the small intestine was opened to relieve the tension, but failed to save the patient's life. A post-mortem examination showed a very large hemmorhage into the peritoneum and proceeding down to the pelvic region. The pancreas also was engorged with blood, and there was general peritonitis.

Dr. Frederick Taylor also made a communication on a case of ACUTE PANCREATITIS.

A patient, aged 68, was admitted into Guy's Hospital on February 3rd, 1899. At a public house in Billingegate he had ordered some rum and had filled up his glass from a bottle supposed to contain water, and drank the whole. This bottle was afterwards said to contain very acid of unknown strength. Pain was given and he vomited freely. Though not apparently much affected at first, he afterwards became collapsed, tachypneic, and cyanosed, and from this report the patient was suffering from emphysema and slight bronchitis. The mouth and lips were slightly excoriated. The following day he appeared to be well, and left at his own urgent request. He went home by train a distance of five or six miles, arriving very feebly and ill, and two days later he returned to the hospital. He was then cyanosed, feeble, with rapid pulse and breathing. There was now no soreness of the mouth or epigastric pain, and pain on awareness was worse, with bronchitis and bronchitis, this being the prominent feature, with increasing feebleness of the pulse until his death on February 23rd. Post-mortal, there was emphysema of the lungs, with purulent bronchitis and pleurisy. Ten ounces of blood were found in the substance of the great omentum, and the pancreas was in a state of interstitial hemorrhagic pancreatitis—enlarged, hard, and infiltrated with blood. There was no peritonitis and no fat necrosis. The kidneys were slightly graver. Dr. Taylor discussed the relation of the condition of the pancreas to that of the chest, and to the ingestion of the oxalic acid. The entire latency of the pancreatic lesion was pointed out, as the other two events combined to mask the symptoms which might have been attached to it.

Mr. Barker remarked on the copiousness of the vomiting in these cases and asked if this had been noted by the authors.

Mr. Bidwell referred to a case in which he had operated last year. He had at first diagnosed pus in the gall-bladder, but at the operation the gall-bladder and ducts were found to be healthy and in pursuing his exploration he let out a quantity of fluid, after which the patient recovered. He had heard, however, that he had subsequently died, and he supposed that a fresh collection had formed.

Mr. Bowley, in reply, said that the vomiting was sometimes very copious, while at others there was only retching.

THE SOCIETY FOR THE STUDY OF INEBRIETY.

At the Quarterly Meeting of the above Society held on Thursday evening, October 1st, Harry Campbell, M.D., F.R.C.S., being in the Chair, at the rooms of the Medical Society of London, Sir William J. Collins, M.D., F.R.C.S., delivered an address entitled "THE INSTITUTIONAL TREATMENT OF INEBRIETY.

He said he approached the question rather from an administrative than a therapeutic standpoint, for he was the first chairman of the L.C.C. Inebriates Acts Committee, and he had taken part in founding the certified reformatory at Farmfield, Horley, and as a visitor of Aylesbury Gaol he had watched the establishment and working of the State Inebriate Reformatory for women recently opened there. The Inebriates Act of 1898 had initiated an entirely new method in the treatment of the habitual offender and opened up new possibilities in the treatment system. The "sanatorium" awakened by John Howard and voiced by Romilly had not yet spent its force. The prison, the asylum, the hospital, the reformatory, the school, indeed every social life at every turn, had for the future its respective place.

Instead of the squauер and brutality that Howard had noted and Hogarth had portrayed we had the model prison, the aseptic ward, the palatial asylum, the reformatory retreat, the charlton colonist, the citius.

Even the victim of his own folly was now the object of disinterested solicitude. Some had regarded the process of amelioration of the lot of the sinner and the not as having gone too far, and denounced with Spartan rigour the softness of this degenerate dissipation. In administrative matters softness of heart was an insufficient compensation for the lack of hardness of head. In view of the difficulties encountered in housing even the industrious poor in the large towns at rents alike payable and paying, he confessed he sometimes felt that in some directions we were in danger of making the way of the transgressor soft. Having said this, he thought that in regard to the inebriate it was right to make the experiment—for as an experiment he looked upon it—of seeing what could be done under the optional powers given to County and Borough Councils by the Act of 1892. The old miserable round of repeated short sentences had proved a sorry and revolting farce as means of reclamation. The prison, the asylum, the hospital, and the reformatory had all their uses in our social betters, but up to the present the results of their contents had sometimes been somewhat perfunctorily performed. The mad and the bad pass by almost imperceptible gradations the one into the other.

The late Samuel Butler in "Through the Lense of Crime as Disease and Disease as Crime. The greatest discrimination was required in so-called "borderland" cases in order to decide how to classify and how to treat the particular individual. Questions of moral responsibility were raised which required the thoughtful consideration alike of the philosopher, the physician, and the jurist, and the practical co-operation both of the large-hearted philanthropist and the common-sense practical politician. We were in danger of allowing the common-place so scornfully denounced by Charles Reade in that splendid contribution to solid fiction "Never Too Late to Mend." Inebriety is called a disease, but it is a disease of the foal, the hysteric, she says, "I cannot"; it looks like "I will not"; it is "I cannot will." Its successful treatment involves the problem of how to rehabilitate a human will. We read of infallible methods and short cuts and royal roads, usually by secret remedies, but these infallible means are the exclusive prerogative of the empiric and the quack. As with Joanna Stephens' remedy for stone which in the eighteenth century excited the attention of Bishops and Parliament, the virtue of such nostrums would probably not long survive the publication of their composition. To restore the physical norm is the first essential, but it is only the beginning of treatment. A man cannot be absolutely and at once withdrawn, both as drink and drug. It is on the moral plane that we must work if we are to reconstruct character and not merely regulate conduct. Hedonism and necessitarianism will prove false guides and uninspiring mentors in the task of individual reclamation and social regeneration, even though they pursue the paths of despotic philanthropy so much in vogue in certain circles. Appeal must be made to higher sanctions than those of pleasure or even prudence. Frank recognition must be conceded to a conscious partnership of each individuality in the architecture of his or her own character. Means which do not appeal to a will free to choose, a will actuated by ideals which transcend natural and purely physical may suffice to mould an automaton but will not restore a character. To this end all treatment should be
GERMANY.

Oct. 14, 1903.

[FROM OUR OWN CORRESPONDENT.]

Berlin, October 10th, 1903.

At the German Surgical Society, Hr. Haskanbruch brought forward a case of Paralysis of the Facial Nerve Treated by Nerve Transplantation.

The case was that of a child in whom there was complete paralysis of the facial of the right side. On May 7th, 1902, an incision was made just behind the attachment of the sterno-cleido-mastoid muscle behind the ear, along the edge of the muscle. The accessory nerve was freed at the point where it entered the muscle, the facial was also freed, and the accessory nerve slit with a fine knife into two unequal portions (two-thirds and one-third). The two-thirds part was drawn upwards and planted into an incision in the facial and attached by a couple of fine silk sutures. The wound was closed by suture, all but the lower angle, into which a strip of iodoform gauze was placed. Union took place readily. After a month's time a "creeping" was felt in the right side of the face, and in the summer the disfiguration was noticed to be less, and by September 21st no paralysis could be noticed when the child was at rest. There was slight power of movement, and the flow of tears from the right eye had ceased. At present only slight traces of the paralysis remained. The right sterno-cleido-mastoid showed but little electrical excitability, and the lower part of the trapezius none at all.

Hr. Dollinger, Pesth, spoke on Subcutaneous Extirpation of Tuberculous Cer-vical Glands. He had operated 128 times on 102 patients. Accurate topographical study was required for the operation. Patients were brought to undergo operation with difficulty from the fear of disfiguring cicatrices remaining. Beck's method gave such cicatrices. His own procedure was the following—The patient was placed with the head raised and the operator sat behind. The skin incision was made at the external auditory meatus, one centimetre backwards and six downwards, gradually deepening towards the glands. The field of operation was lighted by the forehead reflector. The glands were to be separated very carefully, as they were soft and easily torn, where the wound could be readily infected. The wounds generally healed per primam, and no infection took place, even when there was slight suppuration. Bleeding was very slight, and no artery required tying in any case. In the first case the facialis antica vein was torn and had to be ligatured, but this had not occurred again since illumination of the field of operation was practised. A drain was inserted into the wound. In twenty-one cases there was slight suppuration, when a counter opening was made and a drainage-tube inserted. The results were suppuration from external infection in twenty-one cases, five cases were still under treatment, 102 healed by first intention. In most of the cases a swelling remained in the region for two or three weeks, but it gradually disappeared. Recurrence had only taken place in two cases. The subcutaneous operation was tedious and time-consuming, and an iron patience was required; but the results were brilliant and disfiguring cicatrices were avoided.

Hr. Bunge, Königsberg, read a paper on Traumatic Cranial Defects and their Coverings. According to Kocher's view, the closure of cranial defects led to dangerous accidents. The speaker had arrived at other conclusions from late examinations of
twenty-two cases of cranial defect treated in the Königberg Klinik. In thirteen cases the defect was left open. Of these three died, and in ten troubles set in that increased in severity in the course of time. There were giddiness, headaches, and epileptoid conditions. In primary bony covering in five cases the conditions were normal in spite of increased intracranial pressure. In defects covered in secondarily the nervous trouble was headaches that disappeared gradually. Where epilepsy was already present, recurrences and death had taken place; where the defect had remained open, in one case with covering, no attack had taken place in a year and a half. In primary implantation the bony pieces united; in secondary implantation they became absorbed after a few days. He therefore recommended the osteoplastique of Müller-König.

The Beitrage z. Klin. Chir., 39, 1, had a paper by Dr. Max Brun on

Pneumococcus Peritonitis.

After a detailed discussion he arrives at certain conclusions, the chief of which are the following:—

Pneumococcus peritonitis is a comparatively rare disease, more frequent in children than in adults, and in girls than in boys.

It arises either secondarily through disease of the lungs, or from the middle ear, or primarily; the mode of infection in the latter case is not always clear.

Anatomically, the chief symptom is a fibrinous, plastic exudation that leads early to adhesions of bowel and limitation of the process. In the extremest cases the whole mass of intestine may be glued into a lump, surrounded by a purulent mass occupying the whole of the remaining part of the abdomen.

The clinical symptoms are in correspondence with this. In typical cases, especially in children, the commencement resembles an acute peritonitis, upon which a chronic stage supervenes with comparatively slight symptoms.

A probable diagnosis may be arrived at by clinical signs, and from the characteristic qualities of the pus (greenish-yellow colour, odourless, and rich in fibrins). A bacteriological examination alone will place it beyond doubt.

The prognosis is favourable. Spontaneous recovery is possible but rare; recovery after operation the rule. The treatment must consist in free opening of the abscess cavity and drainage.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 10th, 1903.

Pelvic Elevation in Operations.

At the Gesellschaft für Surgery Kraske raised a discussion on a procedure in surgery which to him was a serious danger to the recovery of the patient, although in some cases he admitted its necessity. Paralysis of the neurovascular, emphysema of the abdomen after laparotomy and other minor and temporary accidents were recorded by many authorities on the subject. Of all the dangers and disadvantages attending this method of conducting an operation, that of the circulation was the function most affected by the position. He brought forward two examples of myocarditis on which he had operated in this position. The one operated on was ether. The patients both grew worse after the operation and finally died. He blamed the pelvic elevation for the bad results in both cases, as the elevated position of the pelvis raised the blood pressure of the heart and produced a form of acute dilatation that led to destruction.

In a third case, after four days' constipation in this position following an operation of sectio alta, and when healing appeared to be proceeding favourably, she suddenly died without any warning.

In a fourth case with similar symptoms associated with vomiting of blood and distension of abdomen he reopened the wound and found the omentum pushed up under the liver with the colon strangulated and adhering. After relieving the parts and replacing, the wound was again closed, but the patient soon died. He recollected two cases under Professor Schauta on whom he had performed laparotomy with subsequent constipation after pelvic elevation—the same dislocation of the bowel as in the two cases he had represented above. He wished to repeat that these were taken as experimental cases, as a similar condition had been observed post-mortem in other cases. Thinking that those that previously died were due to careless replacement after the operation, these two were specially noted and replaced with the greatest care, but were found on opening the wound to have fallen into exactly the same position.

Seeing that haematemeses is so common after laparotomy, which has been assumed to be due to embolism and ulceration in the mucous membrane of the stomach, it is only fair to inquire if the elevation of the pelvis alone, particularly in obesity, is not the sole cause of the congestion in the vena gastrica superior, thus producing ulceration in the mucous membrane of the stomach, followed by haematemeses.

Trendelenburg thought that such accidents as Kraske had related were not common after operating in this position, but he admitted that fat people might be affected in this way. He had grave doubts about the two cases of myocarditis being hastened or aggravated by the position, but was inclined to lay the charge to the narcosis, as this class of patient bore it badly. He would not doubt that ileus might occur under such circumstances, but thought it would be rare. He was in favour of keeping his patient as short a time as possible in this position, and under any circumstances, where vomiting or any untoward circumstances appeared, the patient should instantly be placed in the horizontal position.

Iselburg said that he always placed his patient in the horizontal position before applying a bandage, to which he gave credit for having none of those accidents that Kraske related. König recorded several cases where abscesses had occurred in the deeper structures of the abdomen after the operation. Lauten-stein said he had had several cases of paralysis of the peroneus and emphysema of the abdominal covering with haematemeses succeeding the operation. He confessed that he had only one case of ileus which he could not say was due to the elevation of the pelvis. He had a shoulder-rest on his operating-table, which relieved the dragging at the knees. Heidenhain said that he always endeavoured to keep the head about the same level as the pelvis. Röttler related a case of aspiration where he had only removed three-quarters of a liter when the patient suddenly died from the emptying of a diverticulum in the oesophagus from the lowering of the head allowing the contents of the sac to flow back and choke the patient. Göpel thought that ileus after aspiration was unlikely, but admitted that care was necessary from the atony that existing at time of aspiration.

Sir William Bennett, F.R.C.S., in the current Fortnightly, has a letter in which he deals with the suggestion of Mr. H. G. Wells that medical men are as a body essentially "illiterate."
The Operating Theatres.

CHARING CROSS HOSPITAL.

Operation for Apparent Suppression of Urine after Nephorrhaphy.—Mr. Charles Gibbs operated on a woman, aged about 38, who had been admitted suffering from suppression of urine. He said that six weeks previously the right kidney had been sewn up by silk sutures on account of the organ being floating, the sutures passing through the capsule and substance of the kidney. Deep sutures were then placed in the muscles and the edges of the skin approximated. The wound healed by first intention, but there was some dull, aching pain in the loin. The patient left the hospital three or four weeks afterwards, but when at home developed severe pain on the right side and passed no urine. At the time of the present operation she had passed no urine for forty-eight hours. There was a large, ill-defined swelling in the right loin, painful and tender. The patient was extremely ill, temperature 103, and she had had a rigor. The condition, Mr. Gibbs pointed out, was probably due to one of two causes: (1) That the first operation had occluded the ureter, and that a stone or some such obstruction was blocking the left ureter; or (2) that there was no left kidney and that the right ureter was blocked by some cause. Being in doubt, he proposed to open the abdomen, and make sure of the condition of the left kidney. A catheter having been passed once more to make certain that the bladder was empty, the abdomen was opened in the usual way. On examining the site of the left kidney nothing could be felt, the twelfth rib being palpable from one extremity to the other. On the right side of the abdomen, the swelling occupied the right loin, pushing the colon in front of it. The outline of the kidney could be made out behind the latter, but the whole was so indefinite, hard and brawny that it was considered better to deal with it from the loin. The abdomen was therefore sewn up layer by layer, and the nephorrhaphy scar in the loin opened up in its internal one-half. After cutting through the various layers of the abdominal wall, perirenal fat was reached, which was edematous; an attempt was then made to find the pelvis of the kidney and the sutures which were fixing the organ; but this was unsuccessful. In the internal part of the wound at its extreme depth a fluctuant spot was found. A trocar with cannula was passed into this, and two or three ounces of stinking urine were removed. This, Mr. Gibbs said, was probably a hole in the pelvis of the kidney. It was enlarged, and an attempt to pass a bougie was made, but owing to the extreme depth of the orifice it was unsuccessful. As stinking urine continued to trickle out of the wound a glass drainage-tube was fixed in it, and the wound packed with iodoform gauze. The patient's condition as she left the table was good. Mr. Gibbs said the case was very interesting; probably unique; on account of the fact of a single kidney having been fixed and trouble ensuing with the absence of the opposite kidney. The causes of the condition were probably that (1) in sewing the kidney up the ureter had been kinked, or (2) that an inflammation had occurred in the perirenal fat, which had pressed on the ureter. He pointed out that the reason of opening the abdomen was to make certain of the diagnosis. In the absence of the left kidney and the probable presence of inflammation round the right kidney, it was considered better to sew up the abdomen and open the old wound. The failure to find the pelvis and the sutures was owing to the depth of the organ and the amount of inflammatory exudation on the back of the organ, although there was no pus.

The subsequent history of the case was that the patient for three months passed every drop of her urine through the loin. The temperature went up and down, she got thinner and thinner, much pus was discharged with the urine. Further operative measures were considered to save the patient's life, but suddenly one morning the urine was passed in the natural way, and from that time the wound slowly and gradually healed up, less and less urine being passed through it each day. Her present condition is that she passes all her urine in the natural way, there is a tiny sinus in the loin which occasionally discharges a little urine. The patient is fat and well, and has since borne a healthy child. No calculus was passed at any time.

ITALIAN HOSPITAL, QUEEN SQUARE.

Excision of Rodent Ulcer with Regard to its Relationship to Nerve Area.—Mr. Lenthal Cheatle operated on a man, aged 56. The ulcer was situated on the point at which the supra-orbital nerve becomes cutaneous. There were no enlarged lymphatic glands. Tactile sensation and pain immediately around the ulcer were dulled. The ulcer was half an inch wide and three-quarters of an inch long. It had been growing for five or six years, and no fungi could be scraped from its surface or depths. No treatment had been employed. Incisions were planned so as to include the margins which limit the distribution of the second division of the fifth, that is to say, starting from a point immediately below the inner canthus of the right eye and extending downwards on the side of the nose to half an inch below the ulcer (this incision separating the areas of the first and second divisions of the fifth at this point); then starting again from the first point it was carried outwards below the lower lid along the rim of the orbit as far as the most prominent part of the malar bone (which point, of course, corresponds to the outer limit of the second division of the fifth), then carried downwards and slightly forwards in a line with the angle of the mouth to within about an inch of that locality, this separating the areas of the second and third divisions of the fifth. The two longitudinal incisions were finally joined below by a transverse cut: thus an irregular oblong field which included the ulcer in its centre was mapped out for excision. This field was excised down to the periosseum. Microscopical section of the ulcer demonstrated it to be a typical rodent. The raw surface was afterwards skin grafted by Thierach's method. Mr. Cheatle said that this was the first time in which he was able to carry out a suggestion he made to the Pathological Society in April, when he showed rodent ulcers, mapping out different sensory nerve areas. On that occasion he said that if rodent ulcers mapped out nerve areas then the surgeon ought to regard the limits of those nerve areas in mapping out his incisions, and not to trust alone to what appears clinically to be the edge of the ulcer. It would be seen, he pointed out, that the incisions he had made in this case did not include the whole of the second division area, but only those parts of it which it seemed reasonable to suppose were outside the growth. When he read the above paper he pointed out that the incidence of carcinoma is often at the point where the sensory nerve becomes cutaneous, and the case he had just operated on was, he considered, a good example of that rule.
ARMY MEDICAL REFORM.

The recently issued Report of the Royal Commission appointed by His Majesty to inquire into matters connected with the recent war in South Africa contains matter of great public importance. It may be described as one of the most scathing condemnations of a great Government department ever issued. That the War Minister responsible for not a few of the blunders and reckless incompetacies therein disclosed should retain office for a single day after the issue of this Report emphasises the topsyturveydom of the new order of things in the political world. That portion of the document which concerns the medical profession is worthy of careful consideration. The general breakdown of the Army Medical Service in the South African War is not regarded by the Commissioners as within the scope of their inquiry. That position they justify by referring to the Royal Commission of 1900, appointed to inquire into the care and treatment of the sick and wounded in the campaign. On the other hand, however, they have made some inquiry into the personnel and equipment of the Royal Army Medical Service as tested in the war. The first great lesson to be derived from the Report is that before the war the Service had been allowed to fall to a strength inadequate even to a peace footing, and absolutely incompetent to deal with war on any large scale. At the outbreak of the South African War the total establishment of medical officers, exclusive of India, amounted to 540. Their duty, with the addition of 90 emergency civil surgeons, was to provide for (1) Colonial garrisons; (2) two army corps and one cavalry division; and (3) three general and seven stationary hospitals on lines of communication. The insufficiency of this provision was quickly shown in South Africa. The whole of the Army Medical Corps personnel, officers and men, was exhausted in supplying the

First Army Corps sent out, and in manning the base and stationary hospitals, of which many were required on account of the great area covered by the military operations. When the Second Army Corps reached the Cape there was no regular medical service available, and civilians had to be employed both at the front and base at the Cape, as well as at home, where thousands of invalids began shortly to arrive. The estimate of the peace footing was thus shown to be ludicrously inadequate for its purpose. Lord Roberts remarked that the medical suffered perhaps greater disabilities than any of the other war departments. "It was very far from being prepared for expansion, and yet, within a few months, it was called upon to provide officers, non-commissioned officers, orderlies, and nurses for an army three or four times the size of that for which the establishment had been estimated as sufficient." It would be difficult to formulate a more concise condemnation of the whole system of an important branch of a public service than that contained in the statement that it was "unprepared for expansion." Under such circumstances the wonder is that the Army Medical Corps achieved so much in the face of so many well-nigh insurmountable obstacles. Lord Roberts goes so far as to think that the Department would in all probability have proved equal to the occasion had it not been for the disastrous epidemic of enteric fever. The prevalence of that malady, no less than the excessive mortality, constitutes a serious blot upon the campaign. Compared with those of Germany our methods are crude, unscientific, and reckless in their disregard of the commonest sanitary precautions, to say nothing of the defective hospital accommodation and of nursing by untrained orderlies. One of the witnesses, Surgeon-General Jameson, said: "If sanitation had been understood, not alone by our own (medical) officers, but by the rank and file, the military officers and commanding officers, I think it would have saved thousands of lives." Professor Ogston, again, called the attention of the Commissioners to the fact that the German Army Medical Corps have an elaborate system for testing the water supply wherever troops arrive, and for closing impure sources; but in South Africa nothing of the kind was done. In short, the revelations of this Report more than justify the attitude of the members of Parliament and others who, during the war, called attention to the state of the hospitals and the failure of the Army medical administration. Individually, both officers and men performed feats of endurance and of self-sacrifice of which any nation might well be proud. They served, however, under a system proved by the late campaign to be as incompetent and rotten as could well be imagined. The inherent feebleness of that system has been again and again exposed during past years in the medical journals. But exposure, unhappily, led to no reform before the day of trial. It is earnestly to be hoped that in future the establishment of an Advisory Board will prove a step in the right direction. The constitution of that
Board, however, is a matter of crucial importance, for it would be of little use to complicate matters still further by the introduction of fresh elements of social and professional narrowness and class privilege. The introduction of a system whereby all Army surgeons would be kept in touch with the active practice of their profession should be another great advance. Clearly the whole of this branch of the Service requires remodelling on a sound business-like and modern basis, with a proper distribution of responsibility. The reconstruction should constitute an important part of the scheme of Army reform, the demand for which has been made in warning and emphatic voice by the Report on the South African War.

DUST-BORNE DISEASE.

Dust has been far from ineptly defined as "matter out of place," and certain it is that the detritus of most substances can and does get into situations where it may exercise a highly deleterious influence. The dried and rubbed-off particles of objects animate and inanimate may be of themselves harmful and injurious, or they may act as the vehicles that convey even more harmful and injurious particles—bacteria and bacterial spores. Yet dust in itself as inimical to health has received rather scant recognition. The omnipresence of dust and its familiar characters have probably bred in our minds the contempt with which it is regarded, and the good housewife is generally content with removing the dust from her laris et penates without the slightest regard as to where it goes. The domestic dusting, in a word, consists of scattering already-laid dust, and the house is deemed clean if detritus is flicked off books, clothes, and chairs, to be disseminated into the air or shaken on to the carpet. Now dusty occupations are notoriously unhealthy, the unhealthiness depending greatly on the quality of the dust created. Knife-grinders, mill-stone grinders, coal-miners, and gold-miners all suffer greatly from pulmonary diseases, especially those chronic indurative diseases known as the pneumonconioses. The soft, rounded particles that compose coal-dust are known to be less actively irritant than the sharp, acicular detritus of stone and steel; but all are bad. Other troubles, too, arise from the impregnation of the tissues with minute foreign bodies; witness, for example, the granular lids that are so common in residents in Egypt. Grave as are the consequences of the mechanical ingraining of dust, they are reduced to insignificant proportions when compared with the dissemination of pathological organisms by its means. Were it not that desiccation is a necessary accompaniment of the formation of dust—desiccation being fatal to most pathogenic bacteria—the evil would probably be multiplied an hundredfold. As it is, it is serious enough. The facilities which the constant movement of the air supplies for spreading dust are so enormous that nothing can be deemed secure from its influence that is not hermetically sealed. Perhaps in nothing is the pernicious influence of dust so well illustrated as in the relative immunity from infantile diarrhoea that coincides with a wet summer like that which we have just passed through. Epidemic diarrhoea is the cause par excellence of the high mortality of the hot months, and it can be a matter of little doubt that it is by the contamination of articles of food, especially that excellent culture-medium milk, by bacteria-bearing particles of dust that the disease is caused. Hot weather is the time of the greatest activity in the biological world; hot climates always produce a great luxuriance of both animal and vegetable growth; heat is one of the prime factors in the life-conditions of bacteria. The late summer and autumnal rises in the curves of scarlet fever, diphtheria, and typhoid are probably the results in some measure of this increased bacterial energy, but its most striking and immediate reflection is in the diarrhoeal curve. Last summer, like the present one, was wet, and the rise in diarrhoea was low; this summer the same has been the case. Now, as has been well pointed out by Dr. Newsolme, the temperature, as registered by the four-foot earth thermometer, and to which we have all been accustomed to look for the presage of diarrhoea mortality, ceased to give authentic indications when the summer is wet. Ballard's observations, in a word, leave out of account an important fact—dryness. The earth reading may stand above 56°—the "critical" point—for three months, as it did at Brighton last year, without affecting the diarrhoea-rate if there be rain; and, what is more noticeable, equidistantly-distributed rain. The total rainfall need not be high, but so long as sufficient rain fall at short intervals to lay the dust, the deplorable results of the hot weather on the infantile community do not show themselves. As Dr. Peck, of Chesterfield, admirably put it in his last annual report, "The amount of rain does not appear to be of so much importance as the number of showery days." The lesson is obvious. Our municipalities must try to imitate Nature, and produce artificially the effects of showery days; the water-cart and the hose must be in constant and regular evidence throughout the hot days. Intelligent anticipation should characterise the cold weather; organisation, apparatus, and personnel the hot. We rejoice to see signs of appreciation of the dust evil in various quarters. The City of London has passed a new by-law for limiting the nuisance created by the dust arising from the demolition of old buildings, and an influential dust-committee has been formed by the automobilists to experiment with measures for abating the dust on highways. We fear that these efforts are dictated principally by the immediately obvious irritation of eyes and temper produced by dust, but anything that will help to combat so grave a danger to the public health has our sympathy and encouragement. We must all eventually return to dust, but we do not want to do so too soon.
THE USE OF HIGH-PRESSURE STEAM IN GYNECOLOGY.

During the past fifteen years or so a new method of treating uterine hemorrhage and allied affections has been slowly but surely making its way into gynecological practice. In 1886 Professor Snegirew published an account of the successful application of high-pressure steam to the interior of the uterus, with the object of cauterising the endometrium. The method which he adopted of doing so was crude and inefficient, but the principle was the same as that adopted in the improved instruments of the present day. The importance of Professor Snegirew's discovery was at once recognised by Pincus, of Danzig, who had been for some years impressed with the inefficiency of the existing methods of treating uterine hemorrhage. He set himself to improve Snegirew's apparatus, and, with commendable perseverance and in the face of many obstacles, brought his improved apparatus to a high pitch of perfection. Naturally, an appliance for pouring superheated steam into the cavity of that long-suffering organ, the uterus, excited in many minds opposition and even derision; but still supported by the advice and encouragement of gynecologists of the status of v. Winckel, Winter and Fritsch, Pincus succeeded in showing first that superheated steam could be safely applied to the uterine cavity, and, secondly that its application possessed valuable therapeutic effects. Finally, in 1899, before the seventy-first meeting of the Association of German Naturalists and Physicians, Pincus was able to record 833 cases which had been treated by his method in various parts of the world, and of which 749 were returned as either cured or greatly improved. This method, shortly described, consists in the cauterisation of the uterine cavity either by the direct application of superheated steam applied through a suitable catheter, or by the application of a cauter point heated by superheated steam. To the first operation Pincus has applied the term "atmoecysis," to the second the term "zeotomosis." English gynaecology is characterised by so well-marked a spirit of caution that it is not strange to learn that the apparent errors of steam at 115°C. were sufficient to prevent anything but the most tentative use of Pincus' instrument, and that, with the exception of two communications by Dr. Blacker to the Journal of Obstetrics and Gynaecology, for information from British sources as to its value we must turn to Ireland and Scotland. In Ireland, Sir Arthur Macan read a paper on atmoecysis and zeotomosis before the Royal Academy of Medicine in Ireland, in April, 1900, and since then has used the apparatus in many cases with complete success. In Scotland, Professor Sinclair read a paper on the same subject before the Obstetrical Society of Edinburgh, in May, 1900, in which he was able to record eleven patients cured out of fourteen cases. There is no doubt that the method has not received the attention it deserves. Properly used by skilled hands, the dangers supposed to be attached to it are slight, if not altogether non-existent. On the other hand, improperly used, there is no doubt that serious and perhaps irreparable injury may be done with it, especially if the patient is operated upon whilst under an anaesthetic. The application of the steam should be painless; indeed the occurrence of pain shows that something is wrong, and that the application should be immediately stopped; and in order that the degree of pain may be determined, the patient must be conscious. Atmoecysis may be used in many instances as a substitute for, or as an addition to, curettng, but its greatest successes have been in cases of hemorrhage in which curettting and such measures had failed. It is also of special value in cases of inoperable malignant disease of the genital passages. The use of superheated steam in surgery generally for such purposes as the sterilisation of septic cavities and the checking of surface hemorrhage will, we believe, be in the near future of general use, now that gynaecologists have shown its capabilities, and Pincus' methods will receive the attention which they deserve, but which is at present in great part denied to them.

Notes on Current Topics.

Treatment by Correspondence.

If we caught our first glimpse of the "Malade Imaginaire" from our early studies of Molière, we have had ample opportunity of growing familiar with him since we became "licensed to kill and qualified to cure." Grateful though we cannot help being for their dependence on our advice, there are moments of trial in which we are apt to feel that we earn too dearly the financial remuneration we receive from those whom Addison calls "that sickly tribe who are commonly known by the name of valetudinarians." To such as are smarthing from their subservience to the whims of some exacting sufferer from a diseased imagination let us commend the perusal of "Mr. Woodhouse's Correspondence," just published by Methuen and Company. They may thence snatch the fearful joy of getting a bit of their own back. The initials, "G. R.," which appear on the title-page, but faintly cloak the identity of the distinguished author; they act rather on the principle of the apophasia of the rhetorician. The conflicts in which "G. R." has engaged with our own profession have attained some notoriety, and we have felt it our duty in the past to withstand him as openly and vigorously as St. Paul did his colleague in the ministry. The pleasure, then, of laughing whilst "G. R." satirises, not the medical man, but the patient, derives a greater piquancy from the memory of the past. But laughter needs no artificial stimulus as we follow Mr. Woodhouse and Lady Louisa Fitzwigan in their correspondence over their ailments; it rises unbidden to the lips. Moreover, as a study in temperament this is quite a remarkable book. We find the introspection, the selfishness, the contempt for "hysteria" in others, combined with a degree of intellectual culture and shrewdness in other matters, apily
and delicately woven in the characterisation of these two neurotics. "G. R." is an artist in chiaroscuro, and if, as Leonardo da Vinci has advised, "he improves upon the fanciful images that are sometimes seen in the fire," he does so with a finesse that accentuates the imagery by lightening the fancy. One thing we agreeably miss—for the first time in any novel—is the crudity of the lay medical lore. "G. R.'s" pathalogy is above reproach—even to emphysema following whooping-cough. We are not quite sure ourselves of his therapeutics. Perhaps some of our readers whose patients have taken linimentum saponis by mistake can tell us whether emetic measures produce "an extraordinary eruption of soap-bubbles." For the rest, "Mr. Woodhouse's Correspondence" will do much to help the jaded practitioner by throwing the foibles of his neurotic patients into what we may call comic relief. *Dulce est destere in loco*, but still nicer is it if other people can be induced to perform for our benefit.

**Faith.** "Healing."

We have long had our "Peculiar People," and now we apparently have a rival sect, the Dowieites. Neither of them pay us the compliment of thinking we know our own business. So long as it is merely a matter of personal distrust or aversion, we can only bow to the inevitable, but when they demonstrate their want of confidence so practically as to allow their children to suffer untended, other considerations arise. We had hoped that the pernicious nonsense disseminated by "Dr." Dowie during his recent mission to this country would have fallen on stony ground, but that he has secured some proselytes is shown by the recent trial of one Frank Knowles Butterworth at the Manchester Sessions. The ten-year-old daughter of this stalwart fell down a flight of stone steps and fractured her clavicle. Although the child suffered great pain, he forbade his wife to send for a doctor. After two days' treatment by faith and prayer the fracture became compound, and Butterworth consented to let a chemist be consulted, though he drew the line at a medical man. The chemist very properly recommended that she should be sent to the infirmary, but this suggestion was scouted. She was prayed over both at home and at Zion Chapel, and, of all fatuous suggestions, was bidden to keep raising her arm. Fortunately the agony the child was suffering reached the ears of the Inspector of the N.S.P.C.C., who called in medical assistance and prosecuted the father. We fear that the one month's imprisonment that he is now undergoing will be hardly sufficient to exercise a deterrent effect either on him or his sect; but we trust the publicity that the facts thus gain will show people the criminal folly of exercising fractured limbs, and praying for their restoration at the same time. "Dieu," said Napoleon, irreverently, "est avec les gros bataillons." At any rate, He works through natural laws, which it is as well not to set wilfully at naught.

**Compulsory Post-Mortem Examinations.**

The facility for obtaining an autopsy in hospital practice is an inestimable privilege which is never fully realised by the student until he is brought face to face with an obscure case when he is in practice for himself. In how many instances is the riddle of disease obliged to go unsolved owing to the impossibility of further investigation after death? Even in these days where there is scarcely anything hidden which is not brought to the full light of public inspection, the book of knowledge is apt to be prematurely closed at the moment when the physician makes his exit from the death-chamber. An almost sacred jealousy seems then to take possession of the minds of the friends and relatives of the deceased, which no amount of persuasion, however tactfully put, can overcome. It is well known that the objections to a post-mortem examination are chiefly sentimental, though in rare instances they may be of a religious nature. The suggestion has been brought forward that compulsory necropsies would add to medical knowledge and, at the same time, expose unfit or incompetent practitioners. If once the idea could be instilled into the mind of the public that it is not the medical man who would be benefited by such a procedure so much as his future patients, and therefore the race in general, the unpleasantness and natural dread of a post-mortem examination would cease to be thought of, nay, it would even be welcomed as a source of satisfaction to the friends of the deceased. With regard to the exposure of incompetence which might result, it is possible that this might happen in isolated cases, but the best men make mistakes sometimes, and the mere finding of a different pathological lesion after death to that supposed to exist during life does not necessarily show ignorance, but rather tends to illustrate the extreme difficulty there is of giving absolutely accurate diagnosis in a science like medicine, to which no hard and fast laws apply. Moreover, it only serves to show the great importance of performing a post-mortem examination whenever it is possible to do so. The question of rendering these compulsory by law is one which will hardly commend itself to the majority, for it is only by the better education of the public in such matters that reason can hope to overcome feelings.

**The History of Appendicitis.**

*Vixen fortis anti Agamenmona,* and appendicitis existed before it became fashionable. Not to have had appendicitis nowadays is to argue oneself a person without a history; twenty years ago or so one would have been a clinical curiosity. The retentiveness of the world's pathological memory is about on a par with its therapeutic perspicacity. The burst of "Russian influenza" in 1889 flattered people into the idea that they had got a new disease, and yet influenza epidemics had been known to our forbears as intimately as outbreaks of plague, cholera and scarlatina. There is little known about influenza at the present day that was not described by Graves in 1748,
except a putative bacillus. And so with the records of appendicitis. True, its hybrid designation had not been coined to vex the ear of the nosological purist, and the knowledge of its occurrence was not so widely diffused as the knowledge of influenza, but that it was within the purview of at least one pathologist two centuries ago is shown by an excellent description of an abscess of the appendix recently unearthed by Mr. William Wright from Dr. Lawrence Heister's "Medical, Chirurgical, and Anatomical Cases and Observations." From that time onwards mention of diseased conditions of the appendix and of perityphilitic abscesses occur from time to time in the medical literature of the eighteenth century. It is curious, therefore, that Dr. Howard Kelly, in the course of an erudite address to the Glasgow Obstetrical and Gynaecological Society, should have given Dr. Parkinson (1812) the credit of being the first to recognise diseases of the appendix as fatal morbid processes. The fact that previous descriptions does not detract from the originality of Dr. Parkinson's observations, but priority of discovery may be claimed for several other pathologists. Probably careful research would show the same facts had been noted by many physicians in many countries in many ages, for disease of the appendix is not only frequent, but widely distributed. Much of the history of civilised states is made up of the discovery of facts that were well known by neighbouring states, and, indeed, by previous generations in the same state. Appendicitis is probably as old as America; though, like that continent, it was not "discovered," scientifically speaking, till comparatively late in the world's history; it has doubtless disturbed the well-being and curtailed the life of many a man since our ancestors classed the monkey in primeval forests.

Musical Study and Health.

In modern times when the so-called accomplishments find a large place in the education of the young much labour is bestowed upon their study which, in many cases, would be more profitably expended upon more practical subjects. All are not capable alike of receiving instruction, even in the rudiments of harmony, but mere mechanical dexterity can soon be acquired, parrot-fashion, from the hands of the teacher. Should the scholar happen to evince the minutest fraction of talent in the shape of appreciation of musical tone or form, he or she, most often the latter, is immediately forced, like a weakly hot-house plant, by dint of incessant practice and the application of artificial stimuli, until the power of retailing a fragment in a flat, insipid style is doubtfully attained. One type of tutor will insist upon the all-importance of technique, "the triumphant conqueror," while another instructor sacrifices everything for "soul." From the medical aspect very serious objections have been urged against the excessive application to musical study at an immature age, when the child is so susceptible to impressions from without, and this more especially if there are evidences of some natural ability. There is a distinct danger in such a precocious development along emotional lines which, in children of neurotic tendencies or heritage, should always be avoided, if possible. Then again, too little attention is paid, as a rule, to the position of the child's body at the piano. Day after day the neck is craned forward to read the notes, or the head is bent downwards to watch the fingers, and the spine assumes an antero-posterior curve. Such postures are most strongly to be condemned, for when they are adopted, perhaps in a small, ill-ventilated class-room, it can hardly be wondered if an ugly stoop, a condition of anaemia, or an error of refraction be the result. As long as Apollo and Hygeia walk hand in hand there will be no fear that the study of music will in any way imperil the health of the younger generation.

Heredity in Mitral Disease.

The transmission through generations of a tendency to certain morbid conditions of the arterial system, such as arterio-sclerosis, is a well-established clinical fact. The influence of heredity in actual heart disease has not been so fully recognised, and, indeed, the subject is one which is hardly mentioned by some authorities. Dr. Hirtz, of Paris, discussing the factor of heredity in mitral stenosis, relates the case of a family in which three of the six children suffered from mitral constriction, and although the parents were healthy, the two grandfathers died of some probable heart affection. In some cases of family heart disease the lesions are very nearly allied to those of congenital morbus cordis, and appear to arise from some arrested development (nainisme mitrale). It is not uncommon to meet with patients with heart disease who state that their parents suffered from a similar complaint, but the difficulty is to be sure that it is not merely the rheumatic tendency which is transmitted in such cases. If one could be sure of eliminating the influence of acute rheumatism one might reasonably believe in the importance of heredity pure and simple in mitral affections. The question of marriage in such families is a difficult one, for it not unfrequently happens that it is often the direct cause of an aggravation of the symptoms, and it is known that pregnancy is fraught with grave risks under these circumstances. Defects and tendencies to weakness in any organ or tissue may, of course, descend from parent to offspring, and there is no reason why the heart should be an exception to the general rule.

The importance of a clinical examination of the blood is now fully recognised even in cases where the diagnosis does not rest exclusively upon the determination of its chemical composition or the nature or quantity of its formed elements. In reviewing the work of Professor Pieraccini, of the University of Florence, M. Léfas, in the Archives générales de Medicine, draws attention to the celebrated dictum of Hayem, who stated
that in haematology would be found the solution of many great nosological problems. One of the first facts demonstrated by Professor Pieraccini was that in nephritis the tint of the haemoglobin was frequently above the normal, contrary to that which might have been expected judging from the marked pallor so often seen in patients suffering from this disease. But the most important discovery in connection with the blood changes in nephritis is undoubtedly the relation which lies between the number of eosinophile cells present and the degree of intoxication of the system. The percentage of these cells undergoes a diminution in exact proportion to the amount of renal toxæmia present. This fact has been called by Gigli "Pieraccini's sign," and it also finds a clinical application in puerperal eclampsia due to intoxication of the same origin; indeed, it is quite usual to meet with an absolute aneosinophilia. These blood changes have also been observed experimentally in the dog after ligature of the ureters, in which a condition of uræmia was consequently produced. The clinical value of the sign consists in its use in the differential diagnosis of coma, for in that due to uræmia the eosinophile cells will be nearly or completely absent, while their number will remain the same as in the normal state if the condition be due to epilepsy, alcohol, or diabetes.

**Leucæmia and Tuberculosis.**

Oftentimes rich fruit may be found in unlikely gardens. And in the study of the association and relation of one disease to another there is often much of speculative interest rather than practical service. It is, however, very necessary that all by-paths of pathology should be seriously searched, for frequently in the apparently insignificant lies which, when followed, lead to results of the greatest importance. Dr. W. J. Susmann has recently investigated the relations of leucæmia to tuberculosis. It would seem that tuberculosis is rarely found in combination with either the spleno-medullary or lymphatic form of leucæmia. When the combination does occur, it is two and a half times as common in the lymphatic as in the spleno-medullary form. It is six times as common in the male as in the female. The tuberculosis may be found latent and obsolete, or it may supervene as a terminal infection; or, being latent, it may be lighted up as the result of the leucæmia infection. When the two diseases are combined there is a tendency for the total number of leucocytes to be diminished, and the spleen and glands to decrease in size. This apparent antagonism is possibly due to the excess of nucleoalbumin and the increased phagocytic power of the blood, both of which conditions are present in the leucæmic patient.

**A Modern Jephthah.**

Our friends, the anti-vivisectionists, always said it would happen—and now we must confess they were right. Experimentation could not stop at animals; the blood-thirsty scientist would never be satisfied till he had tried his hand on his own species. Well, it has actually come to pass; only the experimenter was not a doctor, but an analytical chemist. To this investigator was entrusted a consignment of certain alleged injurious articles—to wit, aniseed balls—for purposes of analysis. Whether it was a passionate desire to ascertain the truth, or merely a hypersecretion of saliva stimulated by the sight of the succulent sweetmeats, that drove him to the act, we know not, but the fact remains—he ate one. Feeling no ill-effects, he ate another, and then, perhaps feeling he was greedy, he went so far as to continue the experiment on his own daughter. Unaware that she was being immolated on the altar of science, the little girl followed Oliver Twist's example, and asked for more. The newspaper reports do not say whether she got them; possibly, smitten with remorse, the father had prepared for this eventuality by consuming them all himself. However, all ended happily, for when the case came before the magistrate the analyst appeared for the defence and related his experience, and a conviction was averted. We can only trust that no report of this cold-blooded procedure finds its way to Victoria Street.

**Perils by Rail.**

A cursory glance at the annual statistics will show a tolerably long list of dangers which the ordinary railway traveller runs. He may be unfortunate enough to get smashed up in a collision or to find himself in the compartment with a thief or murderer. But in proportion to the numbers carried, the risks are few. We do not, however, find among the tabulated risks that of infection, although the risk exists. Not so long since a small-pox patient travelled a considerable distance in an electric tram, and we find in one of our lay contemporaries that a fever patient, on his way to hospital, travelled for fifty miles in a railway train. How is this to be prevented? We think that any person conscious that he is suffering from an infectious disease who travels by train should be liable to a criminal prosecution; for it is a crime to propagate disease. If the company knowingly books a passenger who is suffering from an infectious disease they should be liable to a severe penalty. If it becomes necessary to convey a sick passenger, one suffering from infectious disease, a special form of ambulance carriage should be provided, and the carriage thoroughly disinfected after each time it is used. If it should come to the knowledge of the officials of the company that a person who was suffering from an infectious disease had travelled in one of their vehicles, the vehicle should be taken off to the sheds and there disinfected before being again used. Two typical cases, showing that some steps should be taken in this matter, occurred recently, one in the North of Ireland, where a fever patient travelled fifty miles to a fever hospital in an ordinary railway carriage; and in the other case a small-pox patient travelled in an electric tram from the extreme south to the extreme north of the city of Dublin. We hope
The Operative Treatment of Haematemesis.

Nowadays little hesitation is felt in undertaking the operative treatment of perforated gastric ulcer, but surgical opinion is by no means unanimous with regard to the propriety of cutting down the stomach in cases of severe haematemesis. First of all the risk to life from haematemesis is comparatively small, and, secondly, it is by no means always easy to alight upon the source of the bleeding, even when it has been alarmingly copious; in fact, without making an incision in to the stomach it may not be possible to discover the solution of continuity. In this respect the perforated ulcers is very different from the bleeding ulcer. Moreover, gastric ulcer is not the only source of haematemesis, which may be caused by hepatic cirrhosis, and the differential diagnosis often presents grave difficulty. Some surgeons prefer to perform gastro-enterostomy, which, it is claimed, tends to arrest the bleeding and facilitates the evacuation of the stomach contents. As to its results in this direction, there is a curious discrepancy of opinion among surgeons, for while some have never seen haemorrhage recur after the operation, others declare that its haemostatic effects are by no means constant. Probably, as suggested by Mr. Butlin, in the course of the discussion at the Clinical Society last Friday, the best plan is to open the stomach and try to find the source of the bleeding. If the search be successful the lesion can be dealt with sec. art., otherwise recourse may be had to gastro-enterostomy, which holds out good prospects of bringing about at any rate temporary recovery.

Organotherapy in Addison’s Disease.

But little advance has been made in the treatment of Addison’s disease since the now distant day when the great physician delineated the chief clinical manifestations of the condition. Dr. Edward W. Adams, in the current number of the Practitioner, has attempted to indicate the results of organotherapy in combating this complaint. His deductions are at least interesting, and to some extent suggestive. There would appear to be a certain class of case of Addison’s disease which derives indubitable benefit from the exhibition of some form of suprarenal substance, though in any given case it remains up to now impossible to determine its probable response to the treatment. In any given case of the disease, selected haphazard, the probability obtains that disappointment will follow on the institution of organotherapy; but that probability is very distinctly less than that attaching to any alternative method of treatment at present known. The last word upon the preparation to be used and its method of administration remains yet to be said. The problem seems to be to get a sufficient and continuous dose of the pure and active principle unchanged into the blood-stream. Intravenous injection is impracticable. Evidently we are far from any trustworthy method of influencing the pathological processes underlying the morbid condition we do well to speak of as “Addison’s disease.”

Operations in Diabetic Subjects.

In discussing the prospects of surgical intervention in the subjects of diabetes, the cases in which the operation is undertaken for diabetic gangrene should be eliminated from the statistics, otherwise a very misleading idea may be formed of the actual danger entailed by the disease. Apart from these cases it would not seem that the risk is such as to deter surgeons from performing even serious operations, especially if the general condition is fairly satisfactory. The possibility of the supervision of diabetic coma is one which cannot well be guarded against, and when death has followed surgical intervention it was due to this complication in the majority of instances. The process of tissue repair in these cases usually proceeds on normal lines, the ultimate result depending far more on the functional state of the kidneys than on the diabetes proper. Of sixty-nine operations on diabetic subjects collected by Dr. C. P. Noble, of Philadelphia, fifty-two recovered and seventeen died, giving a mortality of 24 per cent. Nine of these deaths were due to coma. Other than from coma the mortality does not appear to be extremely high. A good general rule is to postpone operation whenever the proportion of sugar exceeds 2 per cent. until, under a proper regimen, it has fallen.

The Shipley Oddfellows and their Medical Officers.

It is well that the attention of medical men who are willing to take the post of medical officer to a friendly society should be directed to the state of affairs which exists at Shipley and to the manner in which a friendly society, termed the Shipley Oddfellows, have treated their medical officers. Apparently there have been various causes for dispute between the club and its medical officers since September, 1901, arising out of an attempt on the part of the former to compel their medical officers to grant initiation certificates for female candidates on the same terms as for men. Since that date, it appears that the medical officers have given way on various points in order to meet the wishes of the clubs, but that they have refused very properly to give way on the question of the establishment of female clubs, to which they are entirely opposed. In consequence of this, the clubs have given them notice that their services will not be required after the end of the year, and as every medical man in Shipley is involved in the dispute, the clubs intend to import, if they are able to do so, others who will be more subservient. It is sincerely to be hoped that medical men will refrain from answering the advertisements of the Shipley Oddfellows. The future of the medical profession in both England and Ireland depends to a very great extent upon the self-restraint that is exercised by its members.
with regard to the acceptance of posts vacant owing to the forced resignation, under similar circumstances, of a professional brother. Medical men are urged to apply to Dr. Eames, the secretary of the Shipley Medical Union, before accepting any post advertised by the Shipley Oddfellows.

Natural Causes.

The verdict of death from natural causes is one of the euphemisms of coroners' juries when there is a reluctance to censure some neglect or ignorance on the part of the person or persons responsible for the care of the deceased life. It is the favourite verdict in cases of death in childhood, especially for those infants who have been subjected to the pharmaceutical chemist's quackery. If the medicine the counter prescriber ordered is not immediately lethal, 'natural causes' is returned as the verdict. This is wholly wrong. The death does not in such cases result from natural causes; it results in many cases from the neglect of the parent or guardian to call in a medical practitioner, and from the unblushing and lethal quackery of the pharmaceutical chemist. One of the worst examples of this occurred recently near Manchester where the chemist prescribed for a child suffering from broncho-pneumonia a mixture which his printed advertisement described as a cure for the most infectious diseases, such as small-pox, diphtheria, and scarlatina. Under his care the child got worse and died, and the verdict is 'death from natural causes.' And this because the mixture (which analysis showed) contained no poison. It contained, according to the analyst, chlorine of ammonium and potassium, sulphate of potassium and sodium, some ipecacuanha, camphor, and flavouring agents.

Chloroform versus Ether.

It is usually taken for granted that ether is a safer anaesthetic than chloroform on the strength of laboriously compiled statistics. Certain it is that the death roll from the latter is vastly heavier than that from ether, but it does not follow that these figures afford trustworthy data upon which to found an indictment of chloroform. Ether is more particularly employed in hospital practice, and there are no means of ascertaining, even approximately, the occasions in which anaesthesia is induced in private practice where chloroform is principally the only anaesthetic used. In hospital practice chloroform is reserved for special cases—that is to say, the very young or, on the other hand, the aged and patients suffering from pulmonary or other disease contra-indicating the inhalation of ether. It follows that a somewhat higher death rate is only what might be expected, even though the drug be administered by skilled anaesthetists. In private practice, on the contrary, chloroform is administered by more or less inexperienced men who employ no apparatus of any kind and are often pressed for time, and the death rate is therefore comparatively high. A death under chloroform in skilled hands is of the rarest possible occurrence and in probably ninety-nine per cent. of the fatal cases the drug has been given on a towel or handkerchief. We are indeed unable to recall an instance of death under chloroform occurring when a proper inhaler was used, so that it must be extremely infrequent. We incline to the belief that the bad reputation of chloroform is, in the main, due to its incautious or improper administration and not to any lethal properties essentially its own. Of course, even the best inhaler may prove dangerous if imprudently or carelessly handled, but it nevertheless enables the anaesthetist to keep control of the case without waiting for the supervision of alarming symptoms.

The Diaphragm Phenomenon of Litten.

Among the lesser-known physical signs which are more usually regarded as clinical curiosities than actually utilised by students is the diaphragm phenomenon described by Litten in 1892. This consists of a bilateral linear depression appearing as a shadow at the level of the sixth intercostal space, and at a point intermediate between the nipple and anterior axillary lines. The shadow moves from above downwards during inspiration, and in the reverse direction in expiration, while it is better marked during deep respiration. It is best observed in a diffused light or by oblique illumination. The phenomenon is due to the ascent of the diaphragm and its retraction from the borders of the lungs. With regard to its clinical importance, Puglisi (a) has found that it was absent in thirty-nine cases of pneumonia on the same side as that in which consolidation had occurred. The same observer finds that it is also lacking in conditions where fluid or gas is present in the pleural cavity. When the diaphragm is motionless, as in phrenic paralysis or diaphragmatic pleurisy, the sign is again wanting. It would appear, therefore, that some considerable value would attach to this hitherto little-studied clinical phenomenon, as it is likely to be of assistance in the diagnosis of obscure cases of pleurisy or pneumonia in also in morbid conditions involving the diaphragm.

Antityphoid Inoculations.

In a note (b) on the protective effect of antityphoid inoculation, Dr. A. E. Wright deals with the results as shown in two further statistical reports received at the War Office during the last twelve months. It appears that 4,883 out of 55,925 soldiers in South Africa were inoculated, and, according to the returns, the incidence of typhoid was thereby diminished by one-half and the death-rate by five-sixths. These figures, moreover, refer almost exclusively to men inoculated between 1898 and 1900, so that we are at liberty to infer that the protective effects are maintained, at any rate for the period of time covered by this interval, in other words, for a minimum of three years. In view of these results it may appear advisable to the Government to encourage the inoculation of soldiers.

(b) *Lancet*, October 16th, 1903.
belonging to the army in India, where typhoid continues to be a fertile, and, so far an uncontrollable, source of mortality.

A New Form of Intoxication.

A new and most depraving mode of producing intoxication has been found to exist in the Army, and has had attention drawn to it by Major Jennings, D.S.O., in the current number of the Journal of the Royal Medical Army Corps. It consists in the eating of the cordite with which Lee-Metford bullets are loaded, and although the results which follow its use are, at first at any rate, of a most unpleasant character, still it appears to gain a considerable hold over its devotees. Major Jennings, after discovering the existence of this habit amongst certain men under his charge, experimented in corpore sili by sucking a quarter of a strand of it for two minutes. The result was the worst headache he had ever suffered from, accompanied by ringing noises in his ears. The taste of the cordite was sweet and not unpleasant. It appears that the men take cordite, either alone or dissolved in tea or beer, and that the effect upon them is at first an excised form of drunkenness, shown by continuous talk and a tendency to inform one another of all that ever happened to them. This is followed by a heavy sleep, from which it is extremely difficult to awaken the sleeper. When taken in beer it causes its worst effects, and excites its victim to "almost demoniacal actions," while, according to one of Major Jennings' patients, taken by itself it does not cause this intense effect, but only heavy stupor and sleep. Cordite consists of nitro-glycerine, gun-cotton, and a mineral jelly, with the addition of acetone as a solvent, but which of these constituents is responsible for the result is questionable. Nitro-glycerine is well known to cause tinnitus aurium, and its administration, by causing dilatation of the arterioles, may result in the accumulation in the cerebral circulation of an increased quantity of blood, and in large doses untoward consequences. Acetone is well known to act as a narcotic, but it does not appear to enter largely into the composition of the cartridges.

Mr. Arthur C. J. Wilson has been placed on the Commission of the Peace for the West Riding of Yorkshire.

Dr. James Thomas, of Aberystwith, went to Liverpool on the 30th ult., and has not since been heard of. His friends are naturally very anxious as to his fate.

Dr. Charles Porter, of Sheffield University College, has been appointed interim medical officer of health for Sheffield pending the return to duty of Dr. Schofield.

Dr. F. M. Sandwith has been authorised to accept and wear the Insignia of the Third Class of the Order of the Osmanieh, conferred upon him by his Highness the Khedive of Egypt in recognition of the valuable services rendered by him.

Dr. Adam Blackhall, of Crimond, was presented last week with a silver salver on the occasion of his retiring from practice on account of ill-health. A balance remained in hand, which, at Dr. Blackhall's request, was handed over to the funds of the Children's Hospital.

Special Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

[From Our Special Correspondents.]

EDINBURGH.

The New Fever Hospital.—Though formally opened by the King on the occasion of his visit to Edinburgh in the early summer, the hospital has only now so far approached completion as to be available for the reception of patients, and, on account of the pressure on the accommodation in the old city hospital caused by the prevalence in the town of scarlet fever and diphtheria, it has been decided to transfer the convalescent scarlet cases to the new buildings within the next few days, so that it will soon be in actual working order. On the invitation of the authorities the hospital was open for inspection by the medical profession on Wednesday, and by the general public in the three following days, when parties were shown round the hospital by Dr. Claude Ker, the superintendent. The hospital is situated in grounds extending to 130 acres on the southern slopes of Craiglockhart Hill, and looking directly across to the Pentland Hills. It is constructed in a series of isolated pavilions which will accommodate about 650 patients. Nearly half of the beds are devoted to scarlet fever. The wards are divided into two groups by a line of administrative blocks running north and south, and the westmost group are those in which scarlet fever is to be treated, while on the east are the pavilions for diphtheria, measles and whooping-cough, and erysipelas. The diphtheria wards are in close proximity to the superintendent's house, since in that pavilion sudden emergencies are most likely to arise. A ten-bed ward for typhus is isolated from the rest of the hospital in the south-west corner of the grounds, and in the north-west corner special provision is made for small-pox cases. The wards shown to visitors on Wednesday were those for scarlet fever, which were completely furnished and ready for occupation. A special feature of these wards is the position of the sanitary turrets, which, instead of being at the ends of the wards, as usual, are laterally placed, while the south end of the ward is converted into a convalescent pavilion. The advantage of this arrangement is that the sunniest parts of the wards are available for patients' use, and are not filled up by bath-rooms, &c. A visit was then paid to the kitchen and nurses' quarters, in which the comfort of the nursing staff has been carefully considered. The recreation hall is suitable for concerts, &c., and has a gallery at one end with a large oriel window, from which a magnificent view of the town is obtained, at the other end of the building the plan of the building and its organisation the most strenuous efforts are made to obtain such complete isolation as shall render cross-infection impossible, communication between convalescent patients in the grounds being prevented by double hedges. Special attention has been given to the laying-out of the ground by the city gardener, and nearly 16,000 trees have been planted within them. The site of the hospital cost over £50,000, and the total expenditure up to date has been over £100,000.

BELFAST.

Board of Guardians.—At the last meeting of this board it was announced that the Local Government Board had written saying that they did not object to the proposed appointment of a visiting ophthalmic surgeon, and it was decided that an advertisement should be prepared for this officer. The medical staff of the institution have for some time been anxious that the large number of ophthalmic cases always in the
firmary should be handed over to the care of a specialist, and it is satisfactory to see that the guardians and the local Government Board have fallen in with their views.

ACCOMMODATION FOR INFECTIOUS CASES.—An attempt was made at the Board of Guardians to get the Union Fever Hospital converted into a district hospital, so that fever patients might come to it without the stigma of being in a workhouse hospital. The movement was, however, defeated by a large majority, the guardians taking the ground that their business is to look after the indigent poor, and that the rest of the community should be looked after by the City Corporation. The latter body at present places rather an awkward predicament, for since the old Royal Hospital was closed last month there is no place to which fever cases can be sent except the Union Fever Hospital, to which the artisan class naturally object to go. The new fever hospital at Purdy'sburn will not be ready for three years. It seems as if the Corporation would be compelled to lease the old Royal Hospital and utilise it as a fever hospital till the new hospital is ready, though the building is far too large, and has few of the characters of an ideal infectious diseases hospital. If an epidemic were unfortunately to break out now, and a few serious cases of fever were to be recorded by the Public Health authorities, and be certified as not being properly isolated at home, the situation would be an interesting one.

THE HEALTH OF BANGOR.—The quarterly report of Dr. F. Mitchell, medical officer of health, shows a very satisfactory state of things in Bangor, which is practically a suburb of Belfast, though ten miles distant. During the quarter there was only one case of infectious disease notified, and that had been imported from Belfast. The public health was notably good. Dr. Mitchell said, and this he attributed to the efficient sanitary condition of the town. He had reported all the unsanitary houses which he knew of to the Council, and he had to thank them for carrying out recommendations at all times.

Correspondence.

"DISEASES OF WOMEN DUE TO CLOTHING."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the article under the above heading in the MEDICAL PRESS AND CIRCULAR of this week, Dr. W. ... the astonishing statement which I quote below. He says that he broached the subject in 1902 in a provincial medical journal, but he does not now give us any of the facts in his sweeping generalisation.

If chlorosis and anaemia are always due to or associated with haemorrhage from a gastric ulcer, it seems indeed amazing to me what Dr. Williams should be the only observer who has detected the signs and symptoms of such a common pathological condition. If bleeding from a gastric ulcer is the commonest cause of chlorosis and anaemia, how comes it that the fact has not been widely recognised by the profession? Some further elucidations from Dr. Williams are surely called for.

"In the article I endeavoured to show that chlorosis in some degree an almost universal complaint among young women, was the simplest of all forms of anaemia, that due to haemorrhage; that this bleeding took place in the stomach, that it was derived from a gastric ulcer, and that the gastric ulcer was in its turn produced by the stools, or, in other words, by wearing about the waist a tight, unyielding, constricting mechanism which compressed the liver and stomach, disarranged the circulation, and—as far as explained—produced the lesion in question."

Practically every young woman loses blood in the way indicated, and, as a consequence, becomes the prey to anaemia more or less marked; the worst cases of anaemia from this cause occur not in those whose figures have been systematically trained by the stays from infancy, but in those who from previous neglect are taken in hand later in life, and more hasty and violent measures resorted to, as in the case with the poorer classes."

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

October 8th, 1903.

OBITUARY.

The death of Mr. William Johnson Walsham, which took place at 77 Harley Street early last week, will excite universal regret. In his person surgery loses one of its most industrious members, and the medical school of St. Bartholomew's Hospital an esteemed and valued teacher. Mr. Walsham was born in 1847. He was educated privately and was destined at first for the profession of a civil engineer. To this end he was apprenticed to the firm of Maudsley, but he broke his indentures to study chemistry. His proficiency in this subject caused him to turn his attention to medicine, and he entered himself as a student at St. Bartholomew's Hospital. During his career as a student he gained a gold medal for botany at the Apothecaries' Society, and some of the chief prizes in the medical school. He was admitted a member of the Royal College of Surgeons of England in 1871, and then acted as house physician to the late Dr. Francis Harris. His energies, however, were soon turned to surgery, though he graduated as M.B., C.M. at the University of Aberdeen. At St. Bartholomew's Hospital he began as junior Demonstrator of Anatomy, where he ultimately became full surgeon and lecturer on surgery. He devoted more particularly time to orthopaedics and interesting himself also in the treatment of nasaldiseases. For several years he acted as an examiner at the Royal College of Surgeons of England, first in anatomy, and afterwards he had to thank them for carrying out his recommendations at all times.

The death of Mr. Walsham was a blow to the Metropolitan Hospital, whilst at the time of his death he was consulting surgeon to the Hospital for Hip Disease at Sevenoaks and to the Bromley Cottage Hospital. Mr. Walsham was the author of several surgical works, his "Treatise on the Theory and Practice of Surgery," published in 1887, being the best-known, indeed, it is still deservedly popular in its eighth edition. He also contributed numerous papers of professional interest. For some months past he had been ailing, and he was taken ill at Wiesbaden, whither he had gone for rest and change. At his own earnest request he was brought back to England, and he died at his house in Harley Street on Monday. Mr. Walsham married, in 1876, Edith, the elder daughter of Mr. Huntly Spencer, of Hastings, and had left no children. Mr. Walsham was an able surgeon, and a first-rate operator, an excellent lecturer, and a most genial companion. He was buried at Highgate Cemetery on the 9th inst., and a memorial service was held on the same day in the hospital church of St. Bartholomew-the-Less.

DR. JOHN ROCHE.

We regret to announce the death of Dr. John Roche, of Kingston, whose passing occurred last week in Germany. As a young man Dr. Roche entered the Indian Medical Service, and in 1869 he received the thanks of the Governor and Council of Bombay for his services during the cholera epidemic. He wrote a number of interesting articles on such practical questions as constipation, the use of the menstirinity binder, the cure of Hustul, uterine displacements, and so forth. He took the M.D., and M.Ch. R.U.I. as long ago as 1877; he became one of the original members of the D.S.C. of the same university. For some years past he devoted his leisure to literary work. About three weeks ago he left for a tour on the Continent, in company with his son, his death, however, broke down at Heidelberg, where he died.
literature.

THE BRITISH SANATORIA ANNUAL. (a)

This convenient little guide, originally reprinted from the *West London Medical Journal*, is now in its third year of publication, and forms a useful index to a considerable number of sanatoria now available for consumptives in this country. Unfortunately the particulars given are evidently prepared by those intimately interested in the institutions described, and lack the critical and judicious expression of opinion which can only come from outside observation. The arrangement of the descriptions is not so much as facilitates ready reference and the list of sanatoria for men is by no means complete. The work is one which will provide of distinct service, but we venture to think its usefulness would be increased if it were less avowedly an advertising medium.

An appendix contains abstracts of some good papers read at the Tuberculosis Congress of 1901, but the general reader would be better helped if a comprehensive summary of recent work in connection with the hygienic treatment had been given.

The work has a very attractive appearance, but the white flowery covers appear to be more fitted for the drawing-room table than the desk of the busy practitioner.

ELEMENTARY BACTERIOLOGY. (b)

This modest but compact little manual is an attempt to present the fundamental principles of bacteriology in a concise and attractive manner. The author states that the material has been selected and arranged so as to meet the ordinary requirements of Indian students and practitioners. We should have thought that the many recent works on this subject would have been sufficient for the needs of all English-speaking students and the present volume, although in many ways excellent as an introduction to bacteriology, and sufficiently elementary as to be capable of being clearly understood by almost any intelligent reader, is hardly sufficiently complete as to meet the requirements of medical students.

Opening with a discussion on the theory of spontaneous generation, the author passes to the consideration of fermentation, the morphology and general biology of bacteria, the phenomena of putrefaction, the use of antiseptics and disinfectants, and the preservation of foodstuffs. Many of the pathogenic organisms are briefly described, but, as we think, their relation to morbid processes are all too lightly dealt with.

In an appendix, short reference is made to the principles of bacteriological technique, and a short account is given of snake venom and anti-venomous serum.

A small book goes, it is deserving of commendation, but, in our judgment at least, for the requirement of the medical student it is incomplete and much too superficial.

The illustrations are good, but mostly taken from well-known manuals on bacteriology, and even the coloured frontispiece is not original.

LITERARY NOTES AND GOSSIP.

This month’s reviews and journals contain but few articles written by medical men and the essays dealing with professional subjects are meagre and of but little importance. It is to be regretted that our leaders in the profession find but scant opportunity for dealing with some of the prominent periodical literature, for at the present day public opinion is largely determined by and guided to a very considerable extent by expressions which find an opening in essentially ephemeral media.

interesting essay on “The Truth about Christian Science,” by Mr. E. Wake Cook, and it is well that medical men should not neglect a subject which among certain circles is doing much damage.

The current number of *Nature* deals with the recent official reports on the ill-health of the Rand miners, a subject of the greatest importance in the development of South African resources.

The irrepressible Dr. Yorke-Davies writes in the *Gentleman’s Magazine* for October on “Court the Nemesis.”

We have on several occasions referred to the luminous essays of Mr. H. G. Wells, which, during the past year, have been appearing in the *Fortnightly* and *Cosmopolitan*. They have now been issued in book form, and medical men will do well not to neglect “Mankind in the Making” (London : Chapman and Hall.)

Many medical men are ardent lovers of the Suffolk artist, John Constable, who has familiarised us all with the country delights of this sparsely populated district of England. It is certainly not generally known that Constable, in two well-known pictures, figures as a physician. He sat for the head of the physician in “The Sick Lady,” Wilkie’s great work, and later in life he again appears as the physician in Wilkie’s picture of Columbus. He died of consumption. Now near the sweet pastoral country in which his early days were spent there stands the East Anglian Sanatorium.

Although but few medical men have gained distinction among novelists, their wives and daughters have in many instances won conspicuous success in the fields of romance and paths of tragedy. It is perhaps generally known that the English version of “The House of Sin” (London : Maclaren and Co., 1903), the powerful work of Marcelle Tinayre, “La Maison du Pêché,” which has attracted much attention during its appearance in *La Revue de Paris*, has been prepared by Mrs. M. Smyth, the talented wife of Dr. Smyth, the well-known medical superintendent of Altradore Sanatorium.

“The Feeding of Infants and Growing Children,” by Mr. G. Mellin, is an intelligent method of advertisement, in that it formulates the principles of infant alimentation in plain language suited to the public to whom it is addressed. In view of the lamentable waste of infant life directly attributable to malnutrition of this all-important department of maternal function, every effort, interested though it be, to generalise such information must be commended. We would willingly see this concise and well-written little pamphlet in the hands of every mother, and in this wish the author will doubtless concur.

Many past and present students of King’s College Hospital will doubtless be glad to possess the “memorial” picture just published by Messrs. Bennelong Co., of Cheltenham. On a sheet three feet by two is printed in lithography, the hospital exterior in the centre, surrounded with perspective drawings of the interiors of three wards, laboratory, chapel, etc., with medallion portraits of some of the eminent members of the staff who made King’s College and its hospital great, from Sir Thomas Watson, Sir Wm. Ferguson, Todd and Budd, down to the present seniors, Lord Lister, Professors Lionel Beale, Wm. Rose, Watson-Cheyne, etc. Most of these portraits are excellent reproductions, the exception being that of Lord Lister, whom few of the present day would recognise herein.

Statisticians will find much figure-food in Dr. W. J. Barclay’s “Life-Table for New Zealand,” which appears in the current number of *Public Health*. In the same month will be found Mr. John Tatham’s paper
on "Infant Mortality," read at the recent Congress on Hygiene.

Medical News.

Prize Day at Haslar.

The session for the surgeons, Royal Navy, under special instruction at the Royal Naval Hospital, Haslar, terminated on the 29th, when the prizes were given away by Admiral J. Durnford, C.B., D.S.O., one of the Lords of the Admiralty. The Director-General of the Medical Department of the Navy, Sir Henry F. Norbury, K.C.B., M.D., was also present. The following is a list of the marks gained by the respective officers:—Surgeons A. W. Iredell, 4,238; F. C. Robinson, 3,998; C. E. C. Child, 3,892; M. T. Male, 3,825; C. H. Lane, 3,661; R. Thompson, 3,620; W. R. D. Breton, 3,545; E. S. Wilkinson, 3,128; R. Kennedy, 3,053; E. A. G. Wilkinson, 3,039; J. H. L. Page, 3,017; W. E. Ormsby, 2,984; J. J. H. Rooney, 2,979; A. A. Terry, 2,978. The prizes were awarded: Surgeon G. G. Blundell, 2nd, gold medal; Surgeon A. W. Iredell, silver medal and books; Surgeon C. E. C. Child, microscope.

Position of Medical Officer of Health.

At a largely attended meeting of the medical profession held on October 3rd, the following resolution was passed unanimously:—Resolved: That we, the members of the Cork medical profession, view with the greatest indignation the unjust observations which were recently made in public by the Lord Mayor with regard to the examination held for the post of sub- sanitary officer by our medical officer of health, Dr. D. D. Donovan, and we wish to express our entire confidence in him and our complete reliance on his skill and integrity in the discharge of his duty, and in the manner in which he has on all occasions faithfully discharged his duties. N. J. Hobart, chairman; P. G. Lee, hon. sec."

The Royal Waterloo Hospital for Children and Women.

The Board of Governors of this Institution, situated in Waterloo Bridge Road, Southwark (the oldest of its kind in the British Empire), founded by the late Dukes of Kent and Sussex, has just received official notification of the following:—His Majesty the King has graciously signified his pleasure that the hospital shall retain the privilege so long enjoyed (since the reign of His Majesty George III.), and has commanded that the institution shall continue to be styled the Royal Waterloo Hospital for Children and Women.

The Odontological Society of Great Britain.

We are requested to announce that this society is prepared to receive applications for grants in aid of the furtherance of scientific research in connection with dental diseases. Communications should be addressed to the Honorary Secretary, 20, Hanover Square, W.

Death under Anaesthesia.

An inquest was held at Manchester last week on the body of a married woman who had succumbed to chloroform narcosis at the infirmary when about to undergo an operation for carcinoma of the upper maxilla. An exonerating verdict was returned. At the Chesterfield Hospital a married woman suffering from strangulated hernia died on the operating table while still under the influence of ether anaesthesia. The usual verdict was returned.

St. Vincent's Hospital, Dublin.

The Introductory Address at the opening of the winter session was delivered on October 6th by Mr. Tobin, one of the surgeons of the hospital. The address, which we publish to-day in our "Irish Supplement," dealt with the grievances of Poor-law medical officers, and the speaker advised the newly-qualified man "to leave the Poor-law service alone," until such time as it had been placed upon a proper basis. A vote of thanks to Mr. Tobin for his address was moved by Dr. Hickey, of New Ross, and seconded by Dr. Cosgrove, of Kilcock. Dr. Cox presided.

Royal Academy of Medicine in Ireland.

The annual general meeting of the Royal Academy of Medicine in Ireland will be held in the Royal College of Surgeons on Friday, October 30th, at 4.30 p.m., when the report will be submitted, and the election of officers will take place. The names of candidates for office must be in the hands of the secretary not later than Tuesday, October 20th.

Association of Physicians and Surgeons of the Society of Apothecaries, Limited.

At the September meeting of the Council it was resolved that, in the opinion of this Association no Medical Acts Amendment Bill will be presented to Parliament which does not include the following provisions:
1. That all persons registered under the Medical Act of 1858 in respect to qualifications to practise medicine shall henceforth be described as "practitioners of medicine," and all persons registered in respect of qualifications to practise surgery shall henceforth be described as surgeons.
2. That all persons registered under the Amending Act, and under the Medical Acts of 1886, shall be described as physicians and surgeons.
3. That the annual registration certificate shall state that the person mentioned thereon is entitled to practise medicine, or surgery (either alone or in conjunction with midwifery), or medicine and surgery and midwifery, as the case may be.
4. That the title of Doctor may be used by all registered medical practitioners who are entitled under the Amending Act to describe themselves as physicians, or as physicians and surgeons.

It was also resolved: That this Association will actively oppose any Bill not containing provisions 1 and 2.

GUILD OF ST. LUKE.

As we previously announced, the annual medical service organized by the Guild of St. Luke, and which has been held annually at St. Luke's Church, on the first Sunday of October, will be held at St. Luke's on this year on Wednesday, the 21st inst., at 7.30 p.m., and at St. Paul's Cathedral, when the sermon will be preached by the Rev. Prebendary H. Montague Villiers, Vicar of St. Paul's, Knightsbridge. As heretofore, all doctors who are graduates or fellows or members of the Royal College of Surgeons are asked to attend in academic robes. Last year upwards of 1,200 medical men were present, and the space under the dome was largely filled with those in academic dress. The music will be rendered by the London Church Choir Association. Admission to the space under the dome will be by ticket only.

Medical Officers of Health.

The annual dinner of the Incorporated Society of Medical Officers of Health was held at the Holborn Restaurant on Friday evening, October 9th, under the Presidency of Dr. Joseph Groves, J.P., the distinguished medical officer of health for the Isle of Wight. A large number of guests were present, including Sir Wickham Church, Bart., President of the Royal College of Physicians; Dr. Griffiths, President of the British Medical Association; Dr. Whitelegg, C.B., Chief Inspector of Factories; Dr. Dawson Williams, Dr. Kelynack, and Dr. Tatham. A large number of Medical officers of health from various parts of the country were present, and many important speeches were made.
The following have passed the first professional examination for the degrees of Bachelor of Medicine (B.M.) and Bachelor of Surgery (Ch.B.) in the subjects indicated: B. Botany; Zool., Zoology; P., Physics; C., Chemistry:

The following have passed the second professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated: A., Anatomy; P., Physiology; M., Materia medica and therapeutics:

Hutchison (P.), Arthur Innes (P.), James S. Kerr (P.), John Kerr (P.), John H. Keene (M.), Donald M. Carmichael, M., Neil D. Donald (P.), Tom D. McEwan (M.), Duncan T. McTavish (M.), Alexander M. Macfarlane (M.), Alexander S. M. Macgregor (P.), Milne Mctavie (M.), Charles E. McEachry (P.), Roderick McEwen (M.), Donald McLaren (P.), David R. Mitchel (M.), Gavin D. Pryce (P.), Anny M. Yates (P.), Robert S. McKinnon (M.), James S. McKinnon (M.), Professorial examination for the degrees of Bachelor of Medicine (M.B.) and Master of Surgery (Ch.M.).

At the recent professional examinations for the degrees of M.B., Ch.B. the following candidates passed with distinction in the subjects indicated:

The following candidates have passed the first examination in medicine in the subjects indicated:

The undermentioned candidates have qualified on their answering to present their examination for the further examination for honours in the subjects set after their names. Those qualified in two or more subjects may present themselves for the honours examination in all subjects:

Original Communications.

INSECTS AS CARRIERS OF DISEASE. (a)

By R. TANNER HEWLETT, M.D., M.R.C.P., D.P.H.,
Professor of General Pathology and Bacteriology in King's College London; Lecturer on Bacteriology, London School of Tropical Medicine; Physician to the Seamen's Hospital, Greenwich.

Mr. President and Gentlemen—the subject which I have chosen to bring before you to-night is very much in the air at present, and though perhaps of more importance to those who practise in the Tropics, cannot be neglected even in North London.

I shall use the term “insect” in its common acceptation, denoting by it all the small fly, flies and fleas, bugs and beetles, gnats, ticks, and spiders and the like, which our American cousins so characteristically group under the designation of bugs, though the strict zoologist might not agree; he would not call a spider or a mite an insect, for these forms are arachnids.

I propose to omit the consideration of the toxic effects that may be produced by insects—bee and wasp stings, spider bites, and the like; also the local lesions that may ensue from a developmental stage being passed in man as a host—for example, the jigger in the foot, and fly-maggots in various cavities—and to confine myself to those more or less generalised diseased conditions which are transmitted through the bites of, or in some other manner by, insects.

Insects may obviously play a merely passive rôle, carrying mechanically the contagious elements and infecting food and drink, or they may be active agents and directly inoculate the victim by biting. In this last category there are also two classes, one in which the insect acts simply as a lancet and inoculates its victim, as in the case of the tsetse-fly and flea, another in which a developmental stage is passed in the insect, as is the case with the mosquito and the malaria parasite, also the filaria.

The conception that insects may play a part in the propagation of disease is a very old one, though until recently the mechanism of such influence could only be surmised; the germ theory of disease was almost a necessary forerunner to any certain knowledge in this direction. The Latin authors, Columella and Varro, seem to have had some idea that there was a connection between malaria and mosquitoes. Thomas Sydenham remarked that if swarms of insects, especially houseflies, were abundant in summer the succeeding autumn was unhealthy. Nott, in America, as long ago as 1849, maintained that yellow fever was transmitted by a species of mosquito, and the natives of the “fly districts” in Africa, where the horses and cattle suffer from the dreaded tsetse-fly disease, have, as far back as we have any records, recognised the association between this fly and the disease.

The disease to be first definitely associated with an insect carrier was the tsetse-fly disease, or nagana, which attacks horses and cattle in Africa. In large tracts of country, especially in Zululand, no horse, ass, or mule can live, and cattle are seriously attacked. The disease is due to a protozoan parasite belonging to the trypanosomes, the Trypanosoma Brucii, the general characters of which are probably known to most of you. The parasite has an elongated, spindle-shaped body in which are one or two nuclear structures and a vacuole. The body is pointed at one (the posterior) extremity, and is prolonged into a long flagellum at the other (the anterior), while upon one aspect is an undulating membrane which becomes continuous with the flagellum.

In the horse the disease-symptoms are fever with progressive anaemia, edema, and paresis, a fatal result ensuing in two, six, or eight weeks after infection. Through the labours of Lieutenant-Colonel Bruce, infection has been definitely proved to be due to the bite of a fly, the tsetse-fly (Glossina morsitans), or, as there are several species, it would perhaps be more correct to say, of a tsetse-fly. The tsetse-flies are confined to Africa; they are greyish-brown in colour, belong to the Diptera, and are not unlike an ordinary house-fly in general appearance; but in the resting position the wings are closed over each other like the blades of a pair of scissors, whereas those of the house-fly diverge at an angle. They inhabit definite tracts of country, known as “fly belts,” which are generally damp, hot, low-lying localities, either on the borders of rivers or lakes, or at any rate not far from water. (a) The fly alights upon an affected animal, sucks its blood, and thereby infects its own proboscis. If it then bites another healthy animal the trypanosomes are introduced into this during the act. It is a process of simple inoculation; at least, this is the generally accepted view, though some authors have suggested that a developmental stage is passed in the fly.

There are two diseases in man which have recently been found to be associated with trypanosomes. The first of these is trypanosomiasis, or trypanosoma fever, met with in Gambia and other districts of Africa. Its prominent characters are irregular fever, enlargement of the spleen, transient oedema, and transient erythema. Two or three cases have been studied in this country. We do not yet know very much about the mode of propagation of this disease, but from analogy it is highly probable that some biting fly or other insect is the intermediary between man and man. Then recently a trypanosoma has been found to be present in that remarkable disease, sleeping sickness. This affection was formerly met with only in certain districts in West Africa, but of recent years has been spreading eastward as far as Uganda and towards the sources of the Nile, and has been causing tens of thousands of deaths. Its essential features are progressive lethargy until at last the patient is always asleep unless roused. As time goes on the patient begins to lose flesh, muscular tremor becomes marked, convulsions may occur, and ultimately extreme wasting, with bed-sores and coma, ensue. The disease appears

(a) An excellent monograph upon the tsetse-flies, by Mr. Austen, has just been published by the Trustees of the British Museum. He describes seven species.
to run an invariably fatal course after a period varying from four months to as many years. The pro-anopheles form of the malaria parasite would be found to be in a developmental stage in the mosquito. Through the researches of Ross, confirmed and expanded by observers in all parts of the world, this has been found to be the case. As you are aware, a complex metamorphosis takes place in the mosquito, and ultimately the resulting spore-like bodies collect in the salivary or poison glands of the insect, whence they are injected into man when he is bitten. Again, from the point of view of prophylaxis, an important fact that certain species of mosquitoes alone convey the infection, alone are suitable for the development of the parasite. The species in question is not the common gnat, which belongs to the genus Culex, but a rarer form, the Anopheles, and not all the anophelines are suitable hosts. We are perhaps not yet in a position to affirm that the mosquito is the only means by which malaria is carried from man to man; it is proverbially difficult to prove a negative, but all our experience so far goes to show that this is the case. Low and Sambon lived in the Roman Campagna in a most malarious district for several months during the malaria season without contracting the disease, simply protecting themselves from mosquito bites.

Some of the older practitioners still persist in disbelieving that the mosquito is the agent whereby malaria is spread, and adduce the old idea of the opening of the soil, &c., as being the cause of malaria. As regards opening of the soil, an instructive account is given by Middleton, of Singapore, of an outbreak of malarial fever apparently associated with disturbance of the soil. Works were in progress near Singapore to increase the size of the water reservoirs; that is to say, the soil was being spread up. In the course of the work, there was a sudden outbreak of malarial fever among the native labourers, who were previously in good health. Formerly this would have been put down to the opening of the soil. The facts of the case were really as follows: The Anopheles mosquito was present in the district, but since all the labourers were healthy, it could not, of course, convey malarial disease. But on a certain date some coolies from Assam were imported into the district, and these coolies had suffered from malaria. Soon the Anopheles became infected from the malarious coolies, and transmitted the parasite to the originally healthy workmen, with the result that there was a sudden outbreak of malarial fever. The coolies, who might have returned in former days would have been held to prove conclusively that malaria was due to opening up of the soil.

Although so much has been done to elucidate the malaria question, there are still some points that remain unexplained. For example, Italy malaria is unknown, whereas in adjoining districts apparently the same in every respect, it is very rife. The Anopheles being present in both. The same thing holds good in Mauritius, and in England malaria has completely disappeared, although the Anopheles is still found. An explanation of these anomalies might lead to very important results from the point of view of prophylaxis.

As regards the prophylaxis of malaria by a campaign directed against the mosquito, much has been done in Lagos and at Ismailia to show its feasibility. It is not, of course, suggested that the mosquito can be exterminated, but since it seems to fly but a short distance, much may be done to diminish its numbers in a district, and so to diminish the incidence of malaria as well as conducing to the general comfort of the population. Possibly in years to come, parasites that destroy the mosquito will be made use of. Not only should the mosquitoes be destroyed, but the sick should be carefully screened from their attacks; if the carriers of the parasite be prevented from carrying it, or, if viscerally infected of other individuals cannot take place.

---

(a) "Report upon Sleeping Sickness," No. 1, 1903.
(b) ibid., No. II.
As regards yellow fever, the remarkable and carefully planned experiments of the Americans have conclusively shown that this disease is conveyed by a species of mosquito, the *Stegomyia fasciata*, and apparently in no other way. That this is so has been proved not only by direct experiment, but also by applying measures to stamp out the disease, partly by the extermination of mosquitoes by spraying the water, and partly by preventing what mosquitoes there may be from biting the sick. This was done in Havana; but mosquitoes by spraying the water, and partly by preventing what mosquitoes there may be from biting the sick. This was done in Havana; but mosquitoes were not exterminated in a manner similar to that adopted for malaria, every case of which was admitted to hospital, and the sick chamber was carefully screened by wire-gauze screens at the windows and double wire-gauze doors. The result has been that for the first time within the memory of man Havana has been absolutely free from yellow fever! Whereas for the years since 1899, from April 1st to December 1st, yellow fever caused in Havana an average of 410.5 deaths; in the months of October and November (when the disease is usually very prevalent) in 1901 there was not even a single case. For the first time for 150 years Havana has been free from this disease! (a)

So far I have been speaking of diseases, which are considered due to protozoan parasites. Now a few words with regard to some bacterial diseases. The means of spread of bubonic plague has to a large extent baffled epidemiologists. Under good hygienic conditions it is not transmitted from individual to individual. In the epidemic at Sydney, Tidswell (b) remarked that the cases occurred erratically in different parts of the city, and that there was no evidence to show that one case originated another by direct infection. Undoubtedly rats are frequently intermediaries in the conveyance of infection, but how this passes from the rat to man is still unsettled. Simond and Tidswell and others suggest that the fleas are the intermediaries between the rat and man. Galli-Vaerio (c), who has done much work on this subject, considers that this is still unproven. In Central Asia it has been suggested that plague may be transmitted from one individual to another by lice. Hankin has suggested that ants may convey the infection, and so on.

There is little doubt that cholera may be conveyed by flies. Many experimenters have shown that flies may convey the cholera miasm before, during, and after the epidemic in their digestive tract. In several other diseases the agency of insects in their spread has been the subject of research, but I will not burden you with further examples. In the book of Lt. Correa I refer you to the monograph by Nuttall on the subject. (d)

So far I have been speaking of diseases that occur exclusively, or almost so, in the tropics. Now to come to a disease that we probably have in New York, as well as in other places. All of us have probably seen boils, carbuncles, or even abscesses or erysipelas stated by the patient to have followed the bites of certain flies, gnats, and the like, and probably correctly so. Such severe lesions following such an apparently slight cause have in the past been frequently put down to the "bad blood" of the patient. But when you consider how many of these insects delight in filthy offal and fecal matter, the filthier it is the more attractive for them, and that they are not more often seen, and their infrequency seems to me to say a good deal for the defensive mechanism of the human body. A fly after fondly feeding on filthy offal sticks its proboscis, which must be seeking with septic material, into a wound and, what wonder that a boil or carbuncle follows?

May not the septic complications of surgical wounds that now and then occur so inexplicably, and which are a source of anxiety to the surgeon, be occasioned by some contact of the wound with unsanitary materials? I put this forward as a suggestion.

The various species of house-fly are, I am convinced, potent factors in the spread of at least some diseases. As regards epidemic diarrhoea, which is one of the greatest causes of infant mortality in this country, Ballard's investigations some years ago showed that the summer rise of diarrhoeal mortality does not commence until the mean temperature recorded by the earth-thermometer at a depth of four feet reaches about 56°F., and that the maximum diarrhoeal mortality coincides with the mean weekly maximum of the four feet earth-thermometer, and that the slower fall of the earth-thermometer coincides with the slower decline observed in the diarrhoeal mortality as compared with its rise. There is a relationship between the earth temperature and the diarrhoea mortality, but its explanation is another matter. Ballard concluded that the essential cause of diarrhoea is a specific micro-organism whose habitat is the superficial layers of the soil, and the vital manifestations of which are dependent upon certain conditions of season and temperature. It is very doubtful, however, whether there is any specific micro-organism of epidemic diarrhoea; many organisms, given the requisite conditions, may probably cause it. Professor Delépine ascribes the affection to *facial* contamination, especially of milk, the micro-organisms concerned being of the coli and of the enteritidis (Gärtnert) (a), the Medical Officer of Health of Southend-on-Sea, suggests that if instead of Ballard's micro-organism we merely say "an organism whose manifestations are dependent upon conditions of season and temperature," and that this organism is the common house-fly, which, beginning to make its appearance in June, becomes a veritable pest during July and the early part of August; after then its existence tends to become a mere formal one and it decreases in number. He says: "This creature is often termed the harmless fly; I certainly give it the first place as a pathogenic agent during the summer months. It is a useful scavenger if kept in its place, but when allowed to fly straight from the dung or refuse heap to commit suicide in the milk bowl, or alight on the lips of a sleeping infant or walk over meat and other articles of food on the table, I repeat that I consider it the most active pathogenic agent during the summer and the principal cause of summer diarrhoea. It is in milk that it proves most dangerous, for it falls into milk bearing on its body and legs such germs as *Bacillus coli*, *Proteus vulgaris* and *Zerny*, *Bacillus enteritidis* (Gärtnert), etc.

By the aid of flies the typhoid and diphtheria bacilli may easily be conveyed to milk or other food. That flies caused putrefaction was known to the ancients, who gave the name *Musca domestica* because the ointment of the perfumer to stink and putrefy (x 1, Rev. Ver.). Dr. Nash (e) then gives an instructive account of an outbreak of epidemic diarrhoea at Southend during the summer of 1902, which seemed to coincide absolutely with the prevalence of *Musca domestica*.

Dr. Fraser, the Medical Officer of Health for Portsmouth, investigated an outbreak of epidemic diarrhoea that occurred in a certain area in his district during the summer of 1902. (d) The area in question contained 212 inhabited houses with a population of 817 individuals. Among these there were 102 cases of epidemic diarrhoea, of which 30 were fatal. The death rate of deficiency of rain, the heat had not been excessive, and the families that suffered were by no means of the lowest classes, but were composed of the respectable working and middle classes. The houses were new and well drained, and as a rule clean and well cared for. The area in question was neither shut in nor densely populated. But there was in the district an accumulation of rubbish and refuse accomplished by brickmaking. The heat in the summer was very high and by the accumulation of rubbish and refuse formed the conditions suitable for the breeding of flies in the district. Flies were present in myriads, and the inhabitants suffered from a veritable plague of

flies, which swarmed over every article of diet. None of the ordinary conditions associated with epidemic diarrhoea were present in this outbreak, and Dr. Fraser attributes it entirely to contamination of food, especially milk, with large numbers of flies.

We all know how important it is, since all our town milk is so dirty, to sterilise or pasteurise the milk used for infant feeding. This is done by scalding or boiling or the use of one of the pasteurisers supplied by the instrument makers. There are two points in so treating milk which are not attended to as they should be, and I would commend them to your consideration. In the first place the place the milk after heating, if not used at once, should be cooled. If allowed to cool of itself, when the temperature has fallen to 40° C. you get a nutrient soil under the very best conditions for the rapid multiplication of any microbes that happen to fall in. During warm weather, a pint of heated milk may take two to three hours to fall from 40° C. to 30° C., and during this period multiplication of any bacteria present will proceed at an enormous rate. Secondly, the vessel containing the milk should be closely covered with an impervious cover, such as a saucer or plate, to prevent bacteria falling in and the access of flies. If you recommend those in charge of your infant patients to sterilise or pasteurise the milk, do not omit to impress upon them at the same to cover the treated milk, and, if possible, also to cool it.

There is no doubt in my mind that typhoid fever also may be conveyed by the common fly.

In the Spanish-American War, the American troops suffered severely from typhoid fever, just as our own troops did in the South African campaign. A board which investigated the epidemic came to the conclusion that flies were the most active agents in the spread of the disease for the following reasons:

1. The larvae contained faecal matter specifically infected with the typhoid bacillus.
2. Flies alternately visited and fed upon this infected faecal matter and the food in the mess tents. More than once it happened when lime had been scattered over the faecal matter in the pits, flies with their feet covered with lime were seen walking over the food.
3. Typhoid fever was much less frequent among members of messes who had their mess tents screened than it was among those who took no such precaution.
4. Typhoid fever gradually died out in the fall of 1898 in the encampments, with the disappearance of the flies. Typhus occurred at a time of the year when in civil practice this disease is generally on the increase. (a)

In the discussion which took place at the Clinical Society in 1901 on the epidemic of typhoid fever among troops in South Africa, Dr. Trench (b) expressed the opinion that flies played a large part in the dissemination of infection. Flies were present in such abundance that they soon became terrible pests; they came with the army, for in ordinary times they were by no means a serious plague. In the same discussion, Captain Ward, R.A.M.C., also expressed the conviction that flies played a prominent part in spreading the disease. (c) The 10th Hussars, a seasoned regiment, was the first to develop typhoid fever in Ladysmith, and suffered very seriously. The water supply could not be suspected. In the neighbouring camp was the Liverpool Regiment, and this was next attacked; and next to the latter was the 2nd Border Brigade, which was attacked third. On investigation it was found that there had been some years before an enteric camp in the neighbourhood. The food was always covered with a mass of flies. Laboratory experiments carried out to ascertain the possibility of flies acting as carriers of typhoid infection have given positive results.

Majors Firth and Horrocks (d) carried out the following experiments. A dustbin filled with an-emulsion of typhoid bacilli was placed in a sterile box, and flies were introduced and allowed to feed. Plates containing sterile agar and dishes containing sterile broth were introduced at the same time, and after remaining for a few days were removed and incubated. No difficulty was experienced in finding colonies of the typhoid bacillus upon the plates and in recovering it from the broth. The excreta of the flies, however, was proved to contain the bacillus, apparently being attached to the heads, legs, wings, and bodies. In another case an emulsion of typhoid bacilli was added to some fresh typhoid stool and the whole was dusted earth so as to represent imperfectly or superficially buried excreta. This and sterile agar plates were introduced with this concoction into a sterile box and again typhoid colonies were easily found on the plates exposed at the same time, showing that the flies had carried the infection from the excreta.

Some years ago Mr. Burgess showed at a Royal Society soirée an ingenious experiment. He allowed some flies to walk over a culture of the Bacillus prodigiosus, a red pigment producing microbe. The flies were then transferred to a bell jar, at the bottom of which were placed slices of sterilised potato. In the course of three or four days red growths were observed to be forming on the potato, showing that the flies had carried the living Bacillus prodigiosus and had inoculated the sterile potato under the bell jar. This is an experiment that can be carried out by anyone, and is a valuable object-lesson. It has been suggested that flies may convey to the air the tubercle bacilli; they increase the expectation and so may convey the bacillus to food. (c) This is perhaps possible, but is extremely unlikely; nevertheless, it is not pleasant to contemplate flies proceeding from the smitten voter.

I have said enough, I think, to show that insects may be the carriers of a large number of affections, and though perhaps in some cases this mode of dissemination may be the exception, it is nevertheless of sufficient importance to merit attention even in the British Isles.

**MEDICAL SERVICE UNDER THE POOR-LAW.**

*What is the case of the Poor-law medical officers? A price, they say, was put on our services which, at the time it was fixed, was certainly not too high. Since then the cost of education has doubled, our market value has doubled, yet we are refused any increase either of privileges or pay.*

From the *Clinical Magazine,* in which there lately appeared some interesting articles on "Prospects in the Profession," I take the following extract:—The popular mind is still so far from being convinced with the importance of the Poor-Law medical officer that it may not be useless to say that a medical school in the present day, whether conducted by a University, a college, or a Metropolitan hospital, is a very serious and highly organised academic institution spending vast sums on its museums, laboratories, and class-rooms, and carrying on its work by the help of a large staff of demonstrators, lecturers, tutors, and clinical teachers. The modern student, if he wishes to qualify at all, is one of the hardest worked young men to be found. From lectures to practical observation in the laboratory, from laboratory to clinical study in the wards and out-patient rooms, thence to class examinations, and hence to his term and its examinations, his days are spent in a ceaseless round of duties, and his vacations are cut shorter and shorter as he goes on. A modern medical school is no place for an idler, and idlers are sooner or later requested by the authorities to move on. After five or six years of such work, the aspirant gains his legally recognised diploma or degree and enters his name on the Register. Yet we are told that this is not a profession requiring a different type of mind from others. (e)

In this paragraph we find the explanation of the present discontent. A man, after five or six years of arduous study, and after seeing many fall upon the way, completes his course. He takes employment in the Poor-Law Medical Service, and he finds himself treated, as regards pay and consideration, as
if he were a Bob Sawyer. The inadequacy of the pay of the dispensary doctor has been set forth in various ways. For instance, it has been shown that, in many districts, if these medical officers were allowed merely the rate of car-hire given to other Government officials and no pay whatever, they would be better off than they are now. To me also the condition of things was brought home very forcibly in this way. There can be no doubt you will deny schooling. We had studied together at Clongowes and also on the benches on which you now sit. When qualified he had taken a dispensary in the West of Ireland. I had gone to sea the first voyage. We had not met for thirty years and we naturally considered how each had fared. It appeared that at the time of his visit I had already been in the enjoyment for nine years of a pension of £50 a year, an annual payment quarterly, to which every medical officer in the Army becomes entitled practically by the mere act of living. While earning this pension I had in one sense a much better time of it than had he. I had always been more highly paid, and I had been given two months' leave of absence every year. He, poor fellow, was in broken health, only on one or two occasions had he had a month's leave of absence during his whole thirty years, yet he was still working away with an ardour that shamed me. A little later his health completely gave way, and he was accorded, ungraciously, as a matter of grace, a pension of sixty pounds a year. That the contrast of this is stricken in favour of the Army you will agree, and the cases, remember, are in no way exceptional. But wait awhile. At the time I speak of, when these two cases fairly repre- presented conditions of the Army Medical Service generally and of the Poor-law Medical Service in many parts of Ireland, the Army Medical Service was considered a poor one by the united opinion of Ireland, England and Scotland that teachers in all schools addressed students not to take appointments, with the result that the conditions of that Service have since been greatly improved. But perhaps it occurs to someone to say Dispensary Doctors may supplement their salaries by private practice, and therefore those salaries should not be on the scale of the military Service. This, is, no doubt, true in some districts. But there are others, and, unhappily, not a few, where the inhabitants are so poor, the doctors attending their cases so removed from the public eye, that his position is comparable to that of an army surgeon, but to that of a civil surgeon in an out station in India, and it depends, indeed, the larger pecuniary recognition which the latter receives. However, away with comparisons. Far be it from me to imply that medical officers in any branch of the public service are overpaid, farther still to urge promising young students, whose services are much wanted in this slowly developing land of ours, to take their energy and skill elsewhere. Quite different considerations urge me to speak to-day. As long as I have a voice to raise, every word of mine shall go to try and exalt the medical profession in public estimation, and to impress on students that no land requires the services of every one of her children so much as does Ireland at the moment.

As regards our profession, it is, believe me, most short-sighted policy for one branch of it, or even for one member of it, to be jealous of another. Our motto rather should be. 'Help one another. We are all interdependent, and what honestly raises one eventually raises all.

Now as regards the cause of the present quarrel—and, indeed, of all quarrels where the profession demands high pay. When we look closely into it, we find that it is due to the fact that while we offer to the public certain high-class goods, not low in price, but of excellent value, what the street, want from us is a low-class article that would be dear at any price. You have been recently qualified, or are about to be so, have probably uppermost in your minds as regards your profession ideas such as the following—You find yourselves anxious to go on adding indefinitely to the knowledge you now possess, to put that knowledge at the service of the public for payment when you can, gratuitously when occasion demands, and whether for payment or no payment, never to give anything but your best. But what if you may of your rôle in life, you will find a large number of the public, a number daily growing larger, who have made up their minds as to what they will have of you, a mixture, a pill or a blister, to which armory have of late been added Röntgen rays and tabloids. It has been so in the past, it is so today, with the oath as tense a matter.

Now, gentlemen, if the Irish poor are to be treated simply with blisters that will stick, or with mixtures after they have been looked in the face, or with tabloids after they have described the nature of their disease, we are, I think, all agreed that the present pay of the dispensary doctor is sufficient for the occasion. But is this, then, the practice of medicine? It is not. Any medicine as it was generally known in Ireland till we became infected with ideas from across the water. We are continually being told how they manage things better in England, and how our system of medical relief pauperises the people. The facts are, that unhappily a large number of the medical paupers, or so poor that no decent man would expect a fee from them, but it was not the medical profession which made them so. Secondly, that in no land does the medical profession stand and higher practice better than in Ireland. At a time when in England a medical practitioner had to take his way through the back door of his wealthy patients, his fellows in Ireland were associating on terms of perfect equality with everyone in the land. Why is this? Simply because we have always treated, and the public have always encouraged us in treating, our rôle in life as a profession, and not as a trade.

Now, what is the difference? Well, you will find in the resolution, which I took for granted just now was in the minds of each of our newly qualified men—viz., that whether for large fees or small fees, or no fees at all, he would never give anyone he pres-cribed for anything but his best. Now, this requires in most cases a full examination of your patient and a careful consideration of his case. There is a sum of money; it may be two guineas, or one guinea, or five shilling, which, taking into account your patient's necessary expenditure and other things, fairly repre- sents what has been done. If you take less you are in- clined to scamp your work. I speak not absolutely, but with the appliance of the human mind. Well, so, working always at your best, you establish a habit; there is but one class of article in your shop, and if a poor person comes along you give him either that article or nothing at all. The well-to-do public, at least the more enlightened of them, join with us in taking this view of the question. They see that they must suffer from any deterioration in our profession, that they are often benefited by the skill gained by those who practice among the poor, and this, combined with less selfish motives, makes them satisfied to pay fees not based on purely mercantile considerations. So there comes to be between the well-to-do, the poor, and the doctors a mutual helplessness, the interchange of which constitutes the salt that saves us from putrefaction.

It is not an easy task for the profession to formulate what it considers the province of a dispensary doctor to be in a careful and precise way. In fact, it is easier to ask whether do they not extend? What is it that does not influence our health? The air we breathe, the water and food we consume, the work we do, the sights we see, the games we play, everything that acts upon us comes within the doctor's scope. This is no vague generalisation, but a hard, practical fact. The cultured and well-to-do are, it is true, becoming educated in domestic hygiene, but it is not so with the poor. To limit the treatment of their ailments to a bottle of medicine is a mockery
and a crime. The part, therefore, that the dispensary doctor has to play is a very large one. There is practically no limit to the good he can do if he is a man of sense, ability and skill. It is his guard against the countless of disease, to limit its spread, to help those attacked in their struggle with it, to raise the standard of health and to forward in every way the health and well-being of those committed to his care. This is no mean task, and surely the man who is called upon to undertake it may put forward the three demands of the Medical Association—entertain, first, a pension (200 a year) while he works, secondly, a moderate pension when he is no longer able to do so; and thirdly, a month's leave of absence every year in which to recuperate his health or to attend a post-graduate course, so as to keep himself up to date with the advance of science. At the outset of this address I remarked that the necessity to remedy the present condition of things is urgent. There is, however, another reason for pressing on with energy just now. It is that we have in office a Chief Secretary and an Under Secretary possessing, we believe, the will and the ability to help us.

Their records fill us with hope. How can we best look at the doings before them? If only you, Mr. Chairman, could take them for a drive in a motor-car through the districts that bound our southern, western, and northern coasts. It would be a pleasant tour, for it would take you through many beautiful places, but you would also be a sad one, for at every turn there would be something speaking to thoughtful minds of present misery and neglected opportunities. The ruined cabins on the hillsides must awaken thought of the brave men born and reared in them, and how of battles fought and battles yet to be, of a chain of emigration, so much gone over the ship's side that one stands in dismay lest the whole should follow. With these thoughts uppermost you would naturally turn to see what was being done to preserve the remaining few. In the houses you enter there is not much of all that the twentieth century is proud of. On every side you see signs of disease spreading unchecked. The young maimed or dying of tuberculosis disease, the old of cancer, lunacy on the increase, typhoid and typhus calling forth heroism, and striking down those who display it. Perhaps in some cottage you may come across a dispensary doctor doing what he can to cope with the difficulties. It may be a sore throat which, if not isolated at once, would spread diphtheria or scarlatina far and wide, one which my friend of the north-west has just treated with five grains of white arsenic; or it may be a crippled child for whom a Thomas's splint is necessary. If the latter, the doctor will be trying to collect twenty-five shillings, the price of the splint. Not does the Chief Secretary give it away? Perhaps when you get outside and ask, "Where will the other five shillings come from?" Be sure you tell him the custom of the country, "The doctor will give that himself," and don't fail to add, "and well be many out of his fine salary."

A dispensary doctor; what a quantity, what a vast, unmeasurable quantity, of grand, unselfish work is covered by that name. Here and there, it is true, are to be found a few, careless and intemperate in many ways. The casual observer is impressed by them; he goes his way ignoring the hundreds others who day and night are expending their best energies in the service of the poor. Some pathetic incidents of the general public have been shown, and the brave men who have stood in the breach have been unregarded through life. Could we but resuscitate and have among us for this occasion the late Dr. William Smyth, of Burtonport, how his manly heart would respond and glow with pride to saying that the work of the dispensary doctor in Ireland was done in the heroic way by practically every dispensary doctor in Ireland whenever occasion demands. To how many a one could not we who know them apply the words of Browning, inscribed on a tablet erected in Templemore Church in memory of Dr. Smyth—

"One who never turned his back, but marched breast forward."

Never doubted clouds would break,

Never dreamed, though right was worsted, wrong

Would triumph and truth, till truth and wrong

Held we to fall to rise, are baffled to fight better,

Sleep to wake."

In saying this I am not indulging in mere verbosity. I am simply stating matters of fact. From St. Thomas's to St. Vincent's, in every Irish hospital and in every district in Ireland, you will find that doctors are working, whether they are paid or not, as nurses, in the interest of the sick. On my return from Paris on June 25th, I learned that at least Dr. Brendan MacCarthy, a man of whom we at St. Vincent's are justly proud, and who worked with Dr. Smyth on the memorable occasion two years ago, is still marching as he has always marched, "breast forward."

On resuming your journey, you will pass many a pleasant-looking coastguard, with spiggat, scanning the horizon for smugglers, pirates, and hostile fleets, and it may occur to you to contrast this continual outlook for foes, rare and easily recognisable, with the fact that never a glass is turned on the myriads of microscopic enemies which carry devastation over the country—to compare the preparedness of the country for possible enemies at sea with its attitude towards ever-present enemies on land. To drive this lesson home, halt at the first dispensary you meet, and, after talking of the recent outbreak of smallpox, ask the naval officers to have a go through, and the eagerness of the State to snap up every new instrument of destruction, introduce them to the whitewashed room, without one vestige of equipment, and, if he is there, to the Medical Officer of Health, a man who, perhaps, took honours in his time, but at a time when the word bacillus was unknown, and to whom there has been given even one month for a post-graduate study in any laboratory since 1850.

Gentlemen, this is one of the commonplace facts that, as I said at the opening of my address, we must continue urging into the street till we awaken the public to its importance. Once it is practically grasped, forthwith will come a recognition of the true rôle of that composite individual an Irish dispensary medical officer, and a redress of his grievances. In and out of season the profession has tried to force it on the attention of the Government, but in vain. The all-importance of the issue and the lability of our rulers necessitate and constitute the justification of the attitude of the profession towards the Irish Poor-law Medical Service.

Not in the interest of the individual—though his lot, however inadequately set forth by me, is hard indeed—not in the interest of the profession, but in the interest of the public were we to lose sight of the Irish Medical Association, and, for the present, at least, leave the Poor-law Medical Service alone.

MEDICAL EDUCATION AND POST-GRADUATE STUDY. (a)

By Sir WILLIAM S. CHURCH, BART., K.C.B., M.D.,

President of the Royal College of Physicians.

In alluding to the changes which the close of the nineteenth century had witnessed in the organisation of the medical profession at this eventful date, Dr. Church remarked that, even with all our perfection in scientific methods, it was possible that we were really no better observers of physical signs and symptoms than were the first principles of Hippocrates. The definition of the term knowledge was no easy matter, including, as it did, among other things, a proper recognition of facts. Was there a tendency to magnify our
That one-third of the students were qualified men. The first attempt in London to establish anything like a post-graduate course was made in 1888, but it was not a success owing to the fact that opportunities were not afforded for clinical work. Now, the great advantage of an institution like this was the facilities which were offered to qualified men for taking part in the active clinical work of the hospital. It was also of great importance to keep the hospital reserved for practitioners only, for where post-graduates had worked with students in the general hospitals with medical schools, not only did it represent the presence of qualified men, but in practice it was found extremely difficult to adapt the teaching to the two sections of hearers. The benefits of post-graduate instruction no one would deny. The qualified practitioner could in this way work at a subject in which he felt himself to be weakest, perhaps from lack of opportunity to study it before. Especially were the needs of post-graduate study felt by medical men in the Services, who, from the very nature of their work, were apt to fall into grooves. In fact, as time went on, an Army medical officer tended to become more of a soldier and less of a doctor. Similarly, in the sister Service there was the same temptation to get into routine methods.

Ever bearing in mind the primary object of the hospital, which was to minister to the needs of the sick and suffering, it was important to recognise that the public would benefit by the establishment of post-graduate teaching, for this always materially aided in increasing the efficiency of the medical staff, in preventing mismanagement, and in improving the treatment of the patients.

PITFALLS. (a)

By J. F. GOODHART, LL.D., M.D., F.R.C.P., Consulting Physician, Guy's Hospital.

After alluding to our general ignorance of that mysterious vital force which we call "life," and to the many pitfalls encountered by the way during our study of health in particular, Dr. Goodhart proceeded as follows:

In hospitals very little is really known about health except the barest and most surface运营管理 of the body, the co-operative work of the profession, and he was, as a rule, very well up in his work, being seldom found actually incompetent. Specialism was, however, the order of the day. The true specialist was one who, in addition to possessing a wide general knowledge of medicine, had paid special attention to one particular branch, not, as the public would think, to only one organ in the body. The demand for specialists was one which met with a ready response, but it was doubtful if in all cases the quality of the article supplied was equal to that which was expected of it. The danger of specialization was quackery, and the worst of all quacks was he who belonged, or did once belong, to the medical profession. He, only upon the death of the whole practice of medicine. Phimosis or adenoids were not, and could not be, responsible for all the diseases of childhood.

It was most essential for the student to endeavour to hold the posts of clinical clerk or dresser in the special departments of his own hospital, where he would be able to hold a resident post he was practically going through a post-graduate course. At Baltimore, it was estimated

(c) Abstract of Address delivered at the Opening Meeting of the Physical Society, Guy's Hospital, on October 16th, 1903.
It is this familiarity with the processes of disease which we should all cultivate. In hospital practice it is comparatively easy to make a diagnosis, for it is seldom that we fail to find something. But when we come to private practice it is here that the functional derangement bursts upon us in full force. Many functional disturbances are simply hitches in the machinery, rather than actual disease.

Hopefulness through all is as necessary for the patient as it is good for the doctor. Some people seem to have no recognition whatever of the indomitable pluck of the living person, and yet, in spite of this, they may be considered by the public as good counsellors. It is difficult to make a reputation, but more difficult to live up to one. Of "Dr. Sanguine" it is said by patients: "I like him when I am really ill, but I am not really ill." The expression "I cure this or that," heard so often on every side, is not a nice one. We cure hams! Disease gets well while we look on and assist as best we can. If we knew more about health we should think less ill of disease. There is nothing that is required so much in medical study as a knowledge of health by which we can control and gauge it. There is no one sign which is pathognomonic of any disease, and all symptoms and physical signs need to be interpreted by the working of the machinery in health. In many healthy people there will often be found small signs and symptoms of disease while yet they live on, while, on the other hand, there are many sick persons in whom it is difficult to be certain of the presence of any trouble.

The fundus oculi, for example, always needs a very wide knowledge of the conditions seen in health. Think of how many times you have found it so easy to say "This is disease," when perhaps there has been some slight engorgement of the papilla or injection of the vessels. It is so easy to say "This is early inflammation." And so difficult to be sure that it is not within the margin of health. I might go further, and say that there are many conditions which resemble closely the beginnings of disease, but which are quite compatible with sound working, such, for instance, as functional albuminuria. It is generally safe to assume a man to be healthy until we can find actual disease in his organs.

There is the pitfall of routine. The human body rebels against monotony in any shape or form. Let a man draw up a little menu of plasma, glucose, fat, salt and water, and let him stick to it for three months. His experiences at the end of that time would be instructive for those whom he has left behind! In the treatment of disease, routine is especially to be avoided. Even the so-called "rest-cures" are not altogether free from this drawback. Rest as a routine measure is in many cases positively harmful, as is the case sometimes in mitral stenosis. We are too prone to adhere to the old methods and to say in justification: "Why should I question this or that authority?" We must question authority, for even the best teachers are not infallible, and to fail to do so is to fall into one of the worst forms of routine.

The last pitfall is which, like the eruptive disorders, may be difficult to discover at the onset. It is the coaccesis medicae, or the itch to do something. We take and give too much medicine, for drugs do not constitute the only form of treatment of disease. It is the craze also for doing something which in many cases leads us to say, "Let's look and see," and even this may degenerate into a routine. We cannot wait and watch. We have not sufficient confidence. This should be our plea for doing nothing. Our enthusiasm must be tempered by a deliberate judgment. This habit will effectually control this variety of itch, and it will confine drugs to their proper sphere.

NOTES ON A CASE OF MULTIPLE DEGENERATING FIBROIDS AFTER THE MENOPAUSE. (a)

BY BEDFORD FENWICK, M.D.,
Physician to the Hospital for Women, Soho.

This specimen is a uterus filled with submucous fibroid growths, which I removed last Tuesday at the Hospital for Women. The patient's age is 54, and she has had four children—the last being born fourteen years ago. Her menstrual history for the last three or four of her pregnancies were completely normal. The menopause occurred seven years ago. For the last four years she has had irregular, and at times profuse and prolonged, losses of blood, which medicines failed to check. Some two years ago she came under the care of Dr. Galbraith, of Southgate Road, who found a polypus projecting from the cervix and removed it. She was much better for a time, and then the losses occurred. Another hard, almost calcareous, growth showed itself and was removed, and she was again better for a time. On several occasions since, the same losses have occurred, relieved by the removal of other growths. Lately, however, the losses have become more profuse, the patient has lost flesh and strength somewhat rapidly, and the last growth removed by Dr. Galbraith resembled a piece of orange. In the last month, the discharge has become very offensive, thicker and darker in colour. At Dr. Galbraith's request I took her into the Hospital for Women, and on examination found a soft friable mass just inside the cervix, which seemed part and parcel of the growth. The uterus, however, was somewhat enlarged, and felt hard and nodular. She had a temperature of 102°, and a quick, fluttering pulse of 110. From this and the history I diagnosed a sloughing intrauterine fibroid, but confess that the growth felt to the finger exactly like one of a malignant character. The specimen shows the manner in which these small fibroids are shelled out from the muscular wall into the cavity; how the compression upon their surface causes necrosis and sloughing; how very difficult for the practitioner and how disheartening for the patient, it is to treat these cases by piece-meal extraction; how much more satisfactory is the radical treatment by hysterectomy. Two other practical points of importance in this case deserve some notice. First, that it exemplifies very well the growth of uterine fibroids after the menopause has taken place, contrary to the old-fashioned doctrine, and one which apparently is still believed by some, that the cessation of the catamenia inevitably brings about a shrinking in the growth of any uterine fibroid which may be present. This doctrine, I venture to believe, is

(a) Read at a meeting of the British Gynaeceological Society, held October 6th, 1903.
not only entirely fallacious, but is the cause of much needless suffering and danger, or, at the least, grievous disappointment, to many women who patiently wait for year after year for the menopause to put an end to their uterine symptoms, only to find then that these are becoming intensified rather than diminished.

In the second place, this case is interesting because of the manner in which this condition so often simulatates that of malignant disease, and which not infrequently in my experience has led to the diagnosis crushing in its hopelessness to the patient and her friends, but happily disproved by her complete recovery after hysterectomy has been performed. It was certainly fortunate for this particular patient that her doctor had so carefully watched her progress and so promptly sent her into the hospital so soon as septic symptoms showed themselves.

SCLEROSIS OF THE OVARY. (a)

By HEYWOOD SMITH, M.A, Oxon., M.D., M.R.C.P., Lon.,
President of the British Gynaecological Society.

CASE I.—M. L., a single woman, aged 24, came under my notice on September 4th, 1902. Her catamenia, established at 15, had been regular tile previous years, but now one or two or three weeks, and last six days. She had had pain in the left inguinal region, before and during the flow, for the last two years. She had been curedt three months previously, and the next period had been much easier. Vaginal examination disclosed a rather follicular cervix; there was a 2-3 inches in the natural direction of some fundal pain. There were no lateral swellings, but some tenderness in the left fornix. The abdominal walls were rigid.

On September 24th, I operated, when both ovaries were found free and small; but the left was much smaller than normal, and it was removed with the oviduct. On section it was seen to be abnormally thickened and smooth, with scarcely any folds, and the stroma dense with small cysts. The right ovary was left. The patient suffered from chloroform sickness, and, no doubt as a consequence, a swelling (probably a hematoma) formed, which eventually cleared up, but left a good deal of pain behind it. She was subsequently admitted into the Torbay Hospital, where, about the end of December, an abscess in the left fornix burst into the bowel. On January 21st of this year she was operated upon in that hospital, and the right ovary, which was reported cystic, was removed. She continued to suffer pain, and in August I saw her with the swathing in hospital, and examining her with ether, found the uterus free and movable, and considering the pain neurotic, she was put under treatment and is recovering.

CASE II.—E. M. M., aged 33, and married nearly six years but never pregnant, consulted me this year. She had been treated in Cape Colony for inflammation of the ovary, and had to lie up three months. She had had catamenia established at 14, lasting five to six days, with very free discharge and slight supra-pubic pain before the flow. On vaginal examination the uterus was found movable and small, with small follicles; the sound passed in the natural direction for 2.5 inches. On deep pressure on the left side a tumour was felt, slightly elongated, tense and tender. On consultation with Mr. Bland-Sutton, we agreed to perform coeliotomy, and this took place on April 17th.

Operation.—The right ovary was of a small size, and burst during extraction; it was removed. The left ovary was slightly enlarged and corrugated; the oviduct, thickened and blocked with inflammatory deposit, was also removed. On a section being made the ovarian stroma was seen to be dense throughout, with some denser white masses and two small corpora lutea.

I have brought these two cases of sclerosis of the ovary, as they present some features in common, and also one striking difference on which I should like to hear the opinion of the Society. In both there was considerable menorrhagia with dysmenorrhea; the former condition is a frequent accompaniment of disease of the ovaries, while the dysmenorrhoea, and that of an intense form, is constantly associated with sclerosis. It seems that the preliminary inflammation when it becomes chronic is associated with increased blood supply and enlargement of the vessels, and on the stroma becoming thickened and contracted the menstrual molimen gives rise to arterial tension in a tissue which is more or less unyielding. But the chief point I wish to draw attention to in these two cases is the difference in the surroundings of the ovary.

In the former case it is thickened, and on the whole smooth; in the latter, while it is also thickened, it is corrugated on its external surface, and presents the exact appearance of the surface of a brain. Now what is the cause of this difference? Is it in the one case that the stroma is uniformly thickened and very dense, and so contracts uniformly, and in the other that the stroma becomes specially dense in the interstices between the Graafian vesicles and the blood-vessels, and so in its subsequent contraction produces the uneven surface you see?

Clinical Records.

CALCAREOUS DEGENERATION OF A FIBROID TUMOUR. (a)

By HEYWOOD SMITH, M.D., M.R.C.P., &c.

A. R., a married but sterile woman, aged 32, consulted me in March, 1885. Her catamenia, established at fifteen, were regular, lasted four days, and were accompanied with much pain, and in July, 1884, she began to suffer from pain in the sacral portion of her spine. A small, hard tumour could be felt in her hypogastrium. On vaginal examination, the os was found rather far forwards, the uterine sound passed up, back, forwards, and a little to the right for 3.25 inches. Pressure on the tumour from above moved the uterus, but not altogether directly. No haemorrhage.

In August, 1886, she consulted a well-known gynaecologist, who opined that the tumour was not of a kind that would grow rapidly, but in 1887 I found that the tumour had increased in size and hardness, and was more independent of the cervix, in front of which it lay.

In June, 1903, the patient being then aged 50, the catamenia continued, though they were not excessive, but the tumour had grown to two or three inches above the umbilicus and was very hard, and it appeared to be independent of the uterus.

On June 25th, I operated, with the assistance of Mr. Dansey Smith. An incision was made from about three

(a) Read at the meeting of the British Gynaecological Society, October 8th, 1903.
inches above the umbilicus to the pubes (about eleven inches), when a large mottled, pale, hard tumour came into view; this was lifted out of the abdomen. The right ovary, the size of a Tangerine orange, burst, and thick black matter exuded, and another cyst in the right tube also gave way, and was removed. The left ovary was cystic, and, being thin, also burst, and it was removed.

Below, the tumour was attached to the fundus by an apparently elongated pedicle of uterine tissue; an attempt to strip off the tumour was followed by some rather smart haemorrhage, so a ligature was passed round the pedicle and the tumour cut away. The uterus was then found to be studded with several fibroids; the left broad ligament was therefore then tied and cut free; the left uterine artery was caught with an aneurysm needle and ligatured, the peritoneum divided above the bladder, and that viscera was stripped down. The posterior flap was then made, the cervix cut across, the right uterine artery tied, and finally the right broad ligament tied and divided. There was some oozing deep in the pelvis on the left; this was arrested with adrenaline. The cervical canal was touched with strong carbolic acid, the raw surface of the cervical stump was drawn together with three strong silk sutures, and the pelvic floor was then sutured right across. The abdominal wound was closed with three layers, the peritoneum with a continuous suture of fine silk, the muscles and fascia with interrupted silkworm gut, and the skin with a continuous fine silk suture and thirty-one stitches having to be made. The wound was dressed with iodoform gauze and collatin plaster.

On trying to make a section of the tumour it was found to be almost impossible, as the whole substance seemed everywhere permeated with calcareous deposit. Why should some tumours be prone to such degeneration? Has it any connection with the gouty diathesis?

Transactions of Societies.

BRITISH GYNECLOGICAL SOCIETY.
MEETING HELD THURSDAY, OCTOBER 8TH, 1903.

HEYWOOD SMITH, M.D., President, in the Chair.

The President showed a specimen of "Calcareous Degeneration of a Fibroid," and read notes of the case, which will be found on the previous page.

Dr. GIBBON-JONES referred to a case that he had brought before the Society, of a large myoma, in the centre of which was a mass of necrotic tissue, surrounded by a deep layer of calcareous material, which was only discovered on section of the tumour after removal. In that particular case the hysterectomy was performed more on account of the mechanical effects of the tumour than for the other symptoms, though the pathological condition must, had the operation not been performed, have resulted fatally to the patient.

Dr. BEDFORD PENWICK said that as fibroid tumours were so often comparatively harmless till they began to degenerate, the cause of such degeneration was very important. He had noticed that calcareous tumours, of which he had seen a considerable number, invariably, as in the President's specimen, had very small blood-vessels, and in cases he had examined he had found that the blood-vessels were of small calibre in comparison with the size of the tumour they had to supply; he therefore thought that the cause of calcareous degeneration was the want of an adequate blood supply.

Mr. BOWREMAN JESSETT said that the application of carbolic acid to the stump was more likely to promote sloughing than otherwise, and that though it was customary to stitch the flags of the peritoneum together, the general opinion now seemed to be that it was better not to stitch the uterine tissue at all.

Mr. MAYO ROBSON said that he had seen many fibroid tumours in calcareous degeneration, and though the majority were calcareous on the surfaces, and were attached by small pedicles, that was not invariably the case. He instancia a case he had recently operated upon, and in which he had opened an ovarian cyst in the centre of a large fibroid in a lady past the menopause. The cavity contained a pint and a half of fetid pus, and several calcareous masses came out from the centre of the tumour. He could not, therefore, accept Dr. Bedford Penwick's explanation for all cases, but thought that calcareous salt might be deposited in a fibroid in process of atrophy and degeneration, as might be the case in other quiescent growths. He was astonished to hear that anyone could carry on the work of the uterus with the scarred and stenosed cervical wall. He was convinced that cautery properly prepared, and used with care by skilled hands, was the best material possible. He used a single needle with cautery prepared by the xyloil process he had lately described (about the oo size), and ran a continuous suture through the peritoneum from one end of the wound to the other, and carried the stitch back, taking in the internal aponeurosis with the peritoneum; he carried the same stitch through the peritoneum, and tied it off at the end of the original suture. He had absolute confidence in that method, and it was the rarest occurrence to have any trouble arising from it. The surface stitiches of cautery, he inserted separately, and took care not to draw them tightly. When any non-absorbable material, such as silk or silkworm gut, was used there would at times be trouble with the wound.

Dr. RICHARD SMITH said in his experience calcareous fibroids had generally been very large, and had existed for a very long time. He still met with many cases who had great faith in chloride of calcium for menorrhagia, and asked whether that treatment had been employed in this case.

Dr. HERBERT SNOW said that these cases were particularly interesting, partly from their exceptional nature and partly from the entirely pathological causes. He felt some slight doubt whether the term calcareous degeneration was justified, and whether the condition might not in some way be related to a very rare condition found elsewhere.

Dr. JAMES OLIVER pointed out that in the calcareous degeneration of ovarian cysts nothing very remarkable was to be seen in regard to the vascularity, and therefore he did not think that the vascularity, to which the President seemed to attach some importance, accounted for the degeneration; he attributed it rather to some constitutional condition of the patient.

The President, in reply, said that the tumour had not begun to suppurate. It seemed to him that the deposit should have been so uniformly disseminated throughout the whole of the tumour. As he had not seen the patient for sixteen years after he had eighteen years ago found the tumour, he could not speak as to the rate of its growth, nor whether the calcareous degeneration was comparatively recent or had been going on pari passu with the growth of the tumour. No microscopical examination had yet been made, but he would have one carried out. Mr. Rusbrooke, under whose care the patient had been, would tell them the medicinal treatment employed.

Mr. F. RUSBRROKE said that electrical treatment was employed for a short time but he believed the patient had had nothing in the way of drugs except some ergot occasionally.

The President showed specimens of sclerosis of the ovary (notes of which will be found on the previous page) and of salpingitis, reading notes of the latter case as follows:

In May, 1898, I was consulted by a woman, aged 22, on account of a yellow vaginal discharge which had persisted for six months and was sometimes offensive. She had been married for three years and a half, had one child, two and a half years old, which she had nursed for three months, and she had never aborted. The catamenia, established at fifteen, had become too frequent, after some temporary improvement. The fundus uteri was rather bulky and wide; the sound passed 3'-2 inches. She was admitted into
Warrington Lodge in May. Her uterus was not so tender, but the right oviducts were both tender and enlarged, as also were the left ovary and oviduct. 

Operation.—On May 15th, the right oviduct was found enlarged, thick, and hard, and adherent to the ovary; the left removed. The cavity of the ovary opened to a cavity of similar condition, and its extremity, enlarged to the size of an orange, was lying in Douglas’s pouch and adherent there. The ovary was enlarged and cystic, and was in contact with that of the same side. The peritoneum was transparent parovarian cyst, the size of a bantam’s egg. The lumina of each oviduct were found on incision to be blocked with dense inflammatory deposit. The left ovary contained a large corpus luteum. The end of the left oviduct and peritoneum were adherent, and was found adherent into a large abscess full of pus, but it was removed unruptured. The patient made a good recovery.

Dr. MacNaughton-Jones showed a specimen of cirrhosis of the ovary and a degenerating uterine myoma, removed from a patient approaching the menopause, remarking that the ovary was a typical specimen and exemplified what he always maintained, that the clinical symptoms in many cases of ovarian disease were altogether out of proportion to the physical conditions found on examination. In this particular case the woman had been a confirmed invalid for five years, suffering constant pain, with inability to walk. He had removed one ovary and resected the other.

The President, in reply to Dr. Snow, said there were no adhesions round the ovaries. There was no doubt that, as Dr. MacNaughton-Jones remarked, the clinical symptoms in ovarian sclerosis were very much out of proportion to what might be expected from the size of the ovaries, but they could hardly be said to be out of proportion to the disease, which was, he must insist, much more serious than it was generally esteemed to be.

Dr. MacNaughton-Jones exhibited, for Dr. J. R. Cook, of Fairmont, Virginia, a Fellow of the Society, a case of a case of cancer in which, after repeated adhesions, there was some danger of injuring the bowel. He had tried it, and found that it slipped up readily under the peritoneum, and in certain cases might afford protection.

Dr. MacNaughton-Jones also exhibited a specimen of isolated tumour of duct cancer in the axilla, in a patient, 21, 47, who was operated upon for an axillary tumour which proved to be a large encapsulated gland containing a small amount of cystic tissue, there being no other glands involved, and the mamma itself, which was very large (weighing 3 lbs. 4 ozs. on removal), presenting no clinical symptoms whatever of malignancy. The only sign was that this breast was a perfectly normal one for years, with the exception of another. The breast was amputated seventeen days after the axillary growth was removed, together with all the cicatricial tissue resulting from the previous operation, and though search was made in various parts of the breast for any evidence of malignancy, up to the present none had been detected. The carciomatus gland was absolutely isolated, surrounded by adipose tissue, and widely removed from the gland tissue of the mamma.

He then related a case of third coeliotomy in a patient on whom hysterectomy was performed for uterine hemorrhage, and finally read notes of a case of extensive cellitis occurring after convalescence from hysterectomy for myoma.

Dr. J. MANSELL MOULIN said that the only trouble he had had this year in a very large number of hysterectomies was much of the same nature. The large portions commenced a fortnight after the operation, and in the course of a week the uterus had become fixed, and the effusion had increased on the left side till it offered a definite resistance, and he had to remove it. He did through the large incision. He found a collection of pus, small in relation to the amount of effusion, right down behind the uterus. This pus might have been reached by an incision of the vaginal vault, but that would have been working in the dark, and he felt it safer to reopen the abdomen.

Dr. HERBERT SNOW said that with regard to schirrus carcinoma developing in the axilla, a recondite explanation had been offered that it might be owing to the presence there of a supernumerary gland or island of mammary parenchyma, independent of the true mammary; he thought this explanation fallacious, and that cases like the one narrated were open to a more simple solution. There was nearly always a layer of gland tissue prolonged over the edge of the pectoralis minor, which carcinoma sometimes developed and appeared to be quite isolated from the breast proper. Such cancers, of course, rapidly infected the glands, and if not seen early became adherent to the vessels, entailing in their excision the removal of a portion of the axillary vein preserved.

Dr. C. H. F. ROUTH complimented Dr. MacNaughton-Jones on the successful result of the course he had displayed. In many cases, with sudden high temperature without apparent reason, the cause lay in the presence of some deep-seated inflammation which had not been detected, and courageous treatment would often save life. He narrated personal and other observations illustrating the success of the old plan with the single modification that he included merely the edge of the peritoneum. It was hazardous to assert that hernia was not met with after peritoneal surgery. It occurred seventeen years after the operation. With regard to the case of cellulitis, when the peritoneum was stitched over the stump, and unsatisfactory symptoms supervened, he had sometimes with very good effect liberated a little fluid by pushing a sound up the cervix as far as it would go with ease.

Dr. F. A. Purcell said that in supra-vaginal hysterectomy a pouch was left between the cervix and the subperitoneal peritoneum extending across the pelvis, and this pouch was the source of danger. Fortunately, when pus did form there it often burst through the vaginal canal and the patient recovered.

The President explained that he did not make flaps, as supposed by Mr. Jessett, but merely passed sutures horizontally through the cervix after its division, in order to bring the edges together and thus relieve the strain on the peritoneum. The accumulation of pus on the stump alluded to by Mr. Skene Keith had been particularly described by Dr. Milton, of Cairo, who seemed to think that it was the regular thing in abdominal surgery for the patient to be in a state of rigor from that cause. He had seen the thing happen and the pus find its way through the cervix without giving rise to much disturbance.

Dr. MacNaughton-Jones, in reply, said that in the case of the axillary tumour, it was not situated in any adenititious or supernumerary mammary tissue or gland. It was quite three inches away, isolated and imbedded in the axilla. Microscopical section showed the similarity between the duct cancer in it and that found in the mammary gland itself. Further examination was being made of the mamma. He would make a further report on the small myoma which he had shown. It was a verification of his position that hysterectomy had to be determined upon from the symptoms rather than from the size of the tumour. The great advantage of the incision which he had made in the case of cellitis was that the abscess was reached without injury to the peritoneum, a point of the greatest moment. In his opinion, in such a case it was far better than opening in the middle line. In the case of the adenomatous uterus which he had removed after previous coeliotomies for ovarian disease, there was the interesting feature of recurrence of cystic degeneration in the same broad ligament. The adnexa had been completely removed in the previous operations. It was undoubtedly due to adenomatous change in the uterine endometrium.

Dr. BEDFORD FENWICK showed a uterus with
multiple submucous myomatous, notes on which will be found on page 446.

He found this uterus supra-vaginally, but as low down as possible so as to escape the slough, and had disinfect the remnant of the canal with iodised phenol.

In several instances in which he had not taken this precaution, symptoms of cellulitis had followed, and it had then been his practice to pull down and dilate the cervix and scrape the stumps, and this had always been successful. He dissented from Mr. Jessett's view that one should not close the stumps, and he always cut out a wedge of tissue so that the cervix could be drawn together by deep cauter cutsures, a neat stump left, and the peritoneal flap protected from the burrowing of pus from below.

Dr. MacNaughton-Jones said that he always prepared the uterine stump and united the flaps with gut sutures, covering the entire stump with peritoneum. In cases which had not been cutetted, he first disinfected the uterine canal for a short distance. This was done in the case of cellulitis he had described.

BRITISH SANATORIA FOR CONSUMPTION.—XVI.
[BY OUR OWN SPECIAL MEDICAL COMMISSIONER.]

THE ROSTREVOR SANATORIUM, IRELAND.

The beautiful district round Carlingford Lough has deservedly won distinction as a health and holiday resort. Rostrevor is picturesquely placed near the mouth of the Kilbroney River, which falls into a beautiful and sheltered bay at the north-eastern end of Carlingford Lough. Warrenpoint is built along the shore at the northern end of the lough, and is connected with Rostrevor by a two and a half miles' tramway. Warrenpoint is also connected with Omleath on the co. Louth shore by a ferry, and a steamer plies between Greencastle, Omleath, Rostrevor, and Warrenpoint at intervals each week-day.

The district presents many advantages as a desirable health station, and has not a few features particularly desirable for the successful treatment of phthisical cases. Rostrevor especially is well protected from northerly and easterly winds, and lies open to the south-west and west. The surrounding hills secure abundant shelter, but the rainfall is, of course, considerable; nevertheless, the character of the soil and the sloping surface of the land allow the ground to dry speedily.

The Rostrevor Sanatorium is admirably situated in a peculiarly sheltered spot, and yet at an elevation of 350 feet. On the north-east lies the strikingly placed Mourne Mountains, some of which reach an altitude of 600 feet, while to the south fine views may be obtained of the Carlingford Mountains. The well-known health resort of Rostrevor is only three miles distant, and the neighbourhood presents many features of great interest.

Dr. F. Howard Sinclair, the proprietor and resident physician, is also consulting physician to the Belfast Hospital for Sick Children and visiting physician to the First Green Hospital for Consumption and Diseases of the Chest.

The sanatorium, which was opened in August, 1869, is admirably fitted for its purpose. Considerable additions have been made from time to time. The original building consisted of a solidly-built but picturesque mansion, and this is still retained as the resident physician's dwelling. The chief portion of the new building is a peculiarly attractive wooden structure consisting of two floors with a covered verandah at the ends, and a balcony to the upper floor. The rooms are well placed, of convenient size, suitably furnished, fitted with casement windows, and in some instances having French windows which open on to the terrace. An open-air dining-room is a notable feature. All bedrooms are fitted with electric bells, and the entire establishment, including shelters and bungalows, is lit by electric light. The bedrooms can be heated in cold weather.

There are also numerous picturesque sleeping bungalows and two revolving shelters in the grounds, which in construction and from their situation allow patients the maximum of fresh air with the minimum of physical discomfort. Patients spend their entire time in the open, the verandahs and revolving shelters being used in cold and showery weather.

The sanatorium has accommodation for twenty-four patients.

The grounds are rich in attractions, being well wooded, provided with sheltering hedges and having excellent gardens and lawns. The country immediately around the sanatorium offers abundant opportunities for carefully regulated exercise. The soil is gravel and dries quickly after rain, and allows of no lodgment of water. The drainage system is good. Pure water is obtained from a well bored into the granite, while for bath purposes sixty gallons of soft water can be supplied per hour by an hydraulic ram.

Treatment is conducted on strict hygienic lines. Much attention is devoted to diet, and the resident physician takes meals with his patients, superintending the dietary and seeing that each patient is taking suitable and sufficient nourishment. All milk used is taken from tuberculin-tested cows.

Hydrotherapeutic measures are employed in suitable cases. There is a well-equipped electric room, and the Röntgen rays are used as an aid to diagnosis. There is also a complete installation for treatment by high frequency and high potential electrical currents. Amusements are carefully regulated according to individual conditions; some patients are only allowed to read or work on their couches, while others can engage in croquet, putting, gardening, photography or sketching.

Every care is taken to protect patients from sources of infection. During their residence patients are not allowed to visit the neighbouring village or visit friends. Relatives visiting patients may obtain meals at a farmhouse near, as there are no arrangements...
for supplying them at the sanatorium, for very wisely it is insisted that many visitors are not desirable.

Dr. Howard Sinclair and his wife reside at the sana-
atorium, and the patients are constantly subjected to a
judicious medical supervision, and their life discipline
according to a rational régime. A fully trained and
very capable matron directs all nursing duties.

We were much struck by the judicious combination
of home comforts with strict institutional discipline.
On all sides there was abundant evidence of the reason-
able application of the best methods for efficiently and
pleasantly carrying out the principles of the hygienic
treatment of consumption.

The terms are particularly moderate: three and a
half guineas a week, inclusive of medical attendance,
board, daily rubbings and baths. Personal laundry,
special drugs, electrical treatment and a special nurse,
when required, are, of course, extra.

Rostrevor Sanatorium lies some three miles above
Warrenpoint station, but arrangements can be made
whereby a car or cab can meet any train. Dr. Howard
Sinclair uses the services of an Irish patient to feel the
Great Northern Railway to Warrenpoint. Patients
from England or Scotland journey by any of the cross-
Channel steamers to Belfast, or cross from Holyhead to
Greenore.

France.

PARIS, October 21st, 1903.

TUBERCULOUS ADENITIS.

The treatment of bacillary adenitis varies with the
degree of development of the ganglion, says Professor
Broca. When a ganglion commences to be infected it
becomes simply hypertrophied and remains
mobile. At a more advanced period, small points of
softening are felt, which ultimately unite to form a
cyst occupying the greater portion of the gland. Later
still, the ganglion contracts adhesions with the neigh-
bouring organs, a regular abscess is formed, which
finally bursts, leaving a fistula. The treatment differs
for the four phases of the affection. The first treat-
ment should be directed to the general condition of
the patient by the use of iodine, arsenic, iron phosphate
of lime, &c., but the most active element of the medical
treatment consists in pure air (sea-side) and super-
alimentation. Besides the medical treatment a certain
number of local remedies may be tried, such as cuta-
aneous evulsion, application of tincture of iodine, and
interstitial injections of solutions. These last alone merit atten-
tion. The agents employed are generally tincture of
iodine, nitrate of silver, chloride of zinc, Fowler's
solution, iodoform and ether, and camphorated naphth.

These injections offer no trouble where the ganglia-
ons are not suppurring, but in the contrary case the
ganglions should be first evacuated by a trocar. A
third method of treatment consists in the incision of
the ganglion and the curettage of the walls, while
the fourth treatment is that of extirpation of the
degenerated ganglions.

When and how should each of these methods be
employed? Where the ganglions are simply hyper-
trophied and not yet caseous, the general medical

treatment is nearly always sufficient. Where no
results, however, are obtained, then the question can
be put, does extirpation succeed, but
require to be repeated a great number of times.
Further, the introduction of irritating substances into
a ganglion already diseased might provoke rapid
suppuration, peri-adenitis, and fistula. Consequently,
the most preferable treatment is extirpation.

The most considerable case to consider is when the
ganglion has become caseous or softened. Here the injections
are certain to bring about a cure in time, and when

CHLOROFORM AS A TERRIFUG.

According to Dr. Leger, chloroform exercises an
action just as efficacious in the treatment of tapeworm
as male fern, kousou, &c. He prescribes the following
mixture, a quarter to be taken every three-quarters of
an hour:—

Chloroform, 3 j.
Syrop., 3 j.
Water, 8 v.

Before the last dose a purgative of castor oil or

tincture of jalap is prescribed.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 17th, 1903.

At the Naturforscherversammlung Exc. v. Behring
gave an address on

THE ORIGINATION OF PHthisIS AND THE CONTEST
AGAINST IT.

His conviction was that pulmonary phthisis in the
human subject usually had its rise in invasion of the
system by tubercle bacilli in earlier infancy through
the mucous surfaces of the alimentary canal. Virchow
had not been able to determine what tubercle was, and
this knowledge was first reached through etiological
inquiries based on the ideas of Pasteur and Koch.
Nageli's figures were, generally speaking, correct as far
as they applied to thickly-populated areas. These
were that tuberculous patches were to be found in
66 per cent. in all people between the ages of 18 and
30; in 50 per cent. in all between 14 and 18; in 33 per
cent. between 5 and 14; in 17 per cent. between 1 and
5; whilst in children under the age of one no distinct
tuberculous patches or disease centres were, as a rule,
discoverable. The results of testing by tuberculin by
Franz and Berend were in practical agreement with
these figures. Jousset's system of inoscopy, by which
sparsely scattered tubercle in large quantities of fluid
were made visible to the eye, confirmed the figures
quoted. By means of this method the tuberculous
origin of many exudations may be determined. Nearly
all serous peritonitides arise from this source, also
many cases of exudative peritonitis, and fluid collections
in the abdominal cavities of alcoholics, with cirrhosis of
the liver, many of exudative meningitis, inflammations
of joints, many cases of disease of the heart, and other
parts, where formerly no possibility of any connection
with tuberculous infection was thought of.

On account of this general saturation with disease,
nothing could be done by seclusion. At most the
coughing phthisic could be separated from the appar-
ently healthy individual, not in curative institutions,
however, but in houses, as lepers were formerly.

Tuberculous infection was far from being phthisis;
the milder infections went on to recovery, the severer
ones led to death. No case had yet been proved of the occurrence of pulmonary phthisis from epidemiological tuberculous infection, nor had it ever arisen from traumatic infection. Hereditary factors were not decisive, but we could properly speak of a bad prognosis in tuberculous families. Human tuberculosis was generally post-genital; the infant's milk was the chief source of phthisis, for the reason that the breast-suckling, like all other animal young, was wanting in those protective arrangements of the digestive apparatus that in the adult prevented the entrance of disease germs. On the basis of these facts, v. Behring arranged his plan of campaign. An essential advance in milk hygiene had yet to be made by the pasteurisation of milk in place of its production. For the feeding of very young infants care should be taken under all circumstances to provide a milk free from tubercle. People who coughed should be kept away, that those belonging to them might be protected against infection. One could not be strict enough in dietetic regulations in cases of temporary exacerbation of tuberculous disease. Dietetic therapeutics stood, therefore, in the forefront of all temporary residence in institutions. He looked upon protective inoculation as the last aim, the practical carrying out of which he did not regard as impossible. He hoped for it in consequence of the results obtained from inoculation for tuberculosis of cattle. The campaign against bovine tuberculosis he looked upon only as a stage in the march against human tuberculosis; his immunisation was possible by the introduction of relatively harmless living tubercle virus. This would, perhaps, be practicable when his own experiments had shown that as good protection could be obtained through feeding as by inoculation. The prospects would be much more favourable when his own hopes were fulfilled, that the milk of highly immunised cows contained protective material that could be conveyed to the human subject. In conclusion, he explained his position in relation to Koch’s views at the London Congress. Although the danger of transference of disease by butter and meat was not great, the danger of infection of infants by tuberculous milk was not enough emphasised, whether the tubercle bacilli originated in the cow or in the human subject. VIELENDELPHIE. Dr. Th. Kostelesky, of Stuttgart, has a paper on, this subject in the Arbeiten auf d. Gebiete der path. Anat. und Bakt., Bl. iv., intended as a contribution towards a knowledge of the tendency to metastases of pseudo-mucoid ovarian cysts. The case was observed in the Königl. Frauenklinik at Tübingen. A woman, aged 54, had observed for about ten years a great increase in size of the lower part of the abdomen, chiefly on the right side. About a year before coming under observation, the abdomen had suddenly got much smaller, but for two months had been gradually increasing again, but without any other symptoms. A diagnosis was made of papillaryfusoid cystoma of the right ovary and ovario-tommy was performed, from which the patient made a normal recovery. The post-mortem examination revealed a papillary multilocular cystoma, and there were no parts that in appearance gave rise to a suspicion of carcinoma.

After three years there was again increase in size, with ascites, and the abdomen was tapped. Explora-tory laparotomy was then performed, when it was found that there was universal carcinoma of the abdominal cavity. Death took place in seventeen days. The autopsy revealed a cystic tumour of the left ovary with metastases in the peritoneum. The case was of interest in that in the first instance there was a pseudo-mucoid cystadenoma, that three years after the first ovariotomy the second ovary became diseased, and that notwithstanding the papillary growth of the first tumour with rupture, there was a free interval of three years; from the second tumour, not a papilliferous one, and free from discoverable rupture, extensive disease of the whole peritoneum had rapidly followed. That, in spite of the malignant course, the ovarian tumour was not malignant was demonstrated by the microscope, which showed in the metastases the typical structure of the first pseudo-mucoid cystadenoma.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 18th, 1908.

DISCOVERY OF THE CAUSE OF DYSENTERY.

Rosenthal, of Moscow, who has been making elaborate examinations of dysenteric stools, gives an exhaustive account of eighty-five of these, wherein no amoeba were found. It may be remembered that the origin of this disease has long been attributed to amoeba. Rosenthal has been able to demonstrate large quantities of Shiga-Kruse bacilli in a number of cases. Rosenthal, moreover, claims to have discovered the real cause of the disease. In the first week, the colonies were in great abundance, but as the symptoms improved the colonies got gradually less, and finally disappeared on the patient's recovery. In every case the blood and mucus were found to be sterile under the most scrutinising examinations.

MULTIPLE FATTY DEGENERATION.

Katz and Winkler have just published a combined report on their investigation of fatty degenerations. The function of the pancreas is a subject that has given rise to a large amount of controversy without being able to finally close speculation. After reviewing the whole field of literature they resolved to operate on the pancreas by removing section, by transplanting the organ, and by ligaturing it at different places. The operations were conducted under the influence of "morphin-chloroform-narcosis." In the cases of ligation and removal of the gland most of the animals soon died. In those cases where the dogs lingered for a time a sort of "chronic pancreatitis" started to set in, and it was strange to say glycosuria was a very rare occurrence.

This rather falsifies the recent notions entertained of the organ, which was thought to be conclusively proved to be the real source of the saccharine production that acted through the vasomotor on the hepatic function! Whatever be the cause, these experiments go to prove that hemorrhages are very common after the trying experiments, which may be closely allied to the fatty necrosis. In addition to the pancreas becoming fatally degenerate, the spleen was also found to diminish with an associated condition of ischaemia. Katz thinks this state of the blood is more likely to be the real cause of all the morbid changes alleged to take place than any other neuritic alteration. He believes that the gland contains a ferment splitting ferment which when injured brings about the consequences usually observed after an accident to the organ.

ARISTOCRIN.

Braun has been using aristocarin, which is a deriva-tive of quinine and satisfies all the conditions of quinine without the bad after-effects. In malaria and typhus it is equal to quinine itself, and in neuralgia better than the drug. He has used it in seventy of the latter cases, even in those of morbus Basedowii, in large quantities without a toxic symptom, quinine exanthemata, or other bad effect.

PERTUSIN.

Pertussin is another preparation used by Frieser,
The Operating Theatres.

The Medical Press. 453

ST. MARY'S HOSPITAL.

Wiring Fractured Patella.—Mr. Ernest Lane operated on a man, aged 28, who had been admitted three days previously, with considerable lameness and limitation of motion of the knee. During the primary operation, a fracture of the patella was found, and the fragments were wired together and covered with plaster. Mr. Lane says that the lacerated edge of the tibia should be carefully felt for, and that, if it is found at all, it should be sutured with silk, for it is very important not to leave any part of the joint surface exposed to the danger of infection. The wires were passed through the femur and tibia, and the fragments were wired together with stout silk sutures. The wound was closed with a small plaster cast, and the patient was discharged from the hospital in a few days.

ROYAL EAR HOSPITAL, SOHO.

Two Contrast Mastoid Operations.—Mr. Macleod Yearsley operated on two cases of mastoid disease. The first case was that of a child, aged 7. The symptoms on admission were: pain in the left ear, with mastoid swelling, headache, posterior superior mental bulging, and lateral tympanum. The child got slightly better, but the tenderness, the bulging, and the tympanum persisted, together with a temperature of 99°; therefore an operation was decided upon. Mr. Yearsley did the Schwartz operation, that is to say, simple opening of the mastoid. The tissues over the mastoid were slightly brawny, the spine of Henle was well marked. The antrum was easily reached by chisel and gouge, the bone being very soft; the antrum was small, lined with granulations, and contained about five minim of pus. The cavity was carefully curetted and thoroughly purified. On syringing, the fluid did not appear at the meatus. The cavity was packed with iodoform-gauze, and the wound sutured, except at the lower part. The second case was a man, aged 34, who had had chronic discharge from the right ear for about eighteen months. A complete radical mastoid operation had been performed on the left ear two years before. In the right ear the greater part of the middle ear was destroyed, and masses of cholesterol and other material occupied the region of the attic and aditus. The patient suffered from periodic attacks of pain and headache, and also from slight horizontal vertigo. The usual incision was made and the cartilaginous meatus detached and held forward by a gauze retractor. The spine of Henle was well marked. The antrum was reached after tedious work with hard sclerosed bone; the antrum was found full of cholesterolomatous material, and the aditus was enlarged by erosion. As much as possible of the posterior wall of the meatus was removed, together with the outer attic wall and the remains of the carious malleus and incus. The cholesterolomatous matrix was removed, and a flap from the cartilaginous meatus of Körner, the cavity packed with iodoform gauze through the meatus, and the wound sutured. Mr. Yearsley remarked that the two cases were of interest as contrasting the two main methods of operating on the mastoid. Owing to the presence of acute symptoms in the first case one was in doubt, he said, as to the propriety of operating, but cut away a flap from the cartilaginous meatus and packed it after the manner of Körner, the cavity packed with iodoform gauze through the meatus, and the wound sutured. Mr. Yearsley remarked that the two cases were of interest as contrasting the two main methods of operating on the mastoid. Owing to the presence of acute symptoms in the first case one was in doubt, he said, as to the propriety of operating, but cut away a flap from the cartilaginous meatus and packed it after the manner of Körner, the cavity packed with iodoform gauze through the meatus, and the wound sutured. The patient in both cases was made as nearly as possible in the retro-auricular groove. By this means the antrum is more easily reached and the scar more easily concealed. He pointed out that in both cases the spine of Henle was well marked. This, or the supr-meatal fossa when the spine is absent, is the most sure guide to the antrum, and it is in this spot that the excavation of bone should be commenced. It would be noted, he remarked, in the second operation that in removing the bridge of bone lying over the aditus no guide was used; as a matter of fact, the instrument invented by Stäcke for that purpose has long been discarded by its inventor, and although still...
thought to be of use by some operators as a protector to the facial nerve, it is, he thought, of positive danger in the hands of a careless or unskilful assistant. The method Mr. Yearesley pursues is to suck a small piece of sponge into the aditus beneath the bridge. This forms an elastic bed upon which the surgeon can chisel with perfect safety.

A week after operation both cases were doing very well.

\textbf{WEDNESDAY, OCTOBER 21, 1903.}

\textbf{THE PROPOSED REGISTRATION OF NURSES.}

The proposal to have a State registration of nurses is a simple corollary of the principle that now renders that process obligatory upon midwives. The arguments that apply to the one set of circumstances may in the main be used with equal force and relevance to the other. Ignorance on the part of midwives is a danger to the community; midwives brought under the control of the State may not be allowed to follow their calling until they have shown themselves possessed of a reasonable amount of technical knowledge. The name of a midwife thus equipped is entered upon the official Register. Under such a system it is abundantly evident that the only guarantee afforded by registration is one of training and of having satisfied a board of examiners. In all other respects a registered midwife may be absolutely unfitted for the practice of her calling. She may be careless, bad-tempered, impatient, and self-opinionated, in spite of the fact that her name is on the official Register. Clearly, the average medical man would choose a midwife on grounds apart from registration. Nor would he or anyone else be likely to take steps to have an unfit woman removed from the Register, that is to say, short of criminal conduct, a point that is automatically safeguarded. It may be assumed with a tolerable amount of safety that the ordinary medical practitioner owes his success, as a rule, to qualities and acquirements other than those which have enabled him to enrol his name on the Register of his profession. Nevertheless the fact remains that registration is not regarded by the State as essential to the provision of a legally qualified public medical service. As everyone knows, the registration of medical men is not compulsory and its absence simply imposes certain not very serious civil limitations upon the non-registered practitioner. On the other hand the State fails absolutely in the implied bargain to stop medical practice by non-registered and non-qualified persons. The system of registration, therefore, as applied to the medical profession is imperfect, contradictory and anomalous. Applied to midwives the same principle is not likely to be attended with more distinguished results, inasmuch as it has been found impossible wholly to forbid practice by unqualified and unregistered midwives. The Registration of Midwives Bill was carried in the teeth of the protests of the majority of the medical profession. We regard the measure as objectionable in various ways, chiefly, perhaps, in its creation of a new class of hybrid and parasitic practitioners. The final step of registration was, in our opinion, uncalled for, and was in reality a concession by the Government to the pressure of a small but energetic band of sentimentalists. It is now proposed to extend a similar principle to nurses. The reasons for this suggested new departure are not apparent. Under existing conditions it is easy for a nurse to assume the position for which she is fitted by tact, training, temperament, and technical acquirements. She will be made neither better nor more dignified by the fact that her name is enrolled upon a Register. The main bedrock fact underlying the situation is that the essential nature of a nurse's duties are administrative. For the intelligent discharge of those duties, it is true, she requires careful training and experience, and she may in some instances be called upon to act upon her own responsibility in the interest of her patient. For all that the fact remains that the place of the nurse is to administer treatment under the directions of the duly qualified medical man. In order to protect the public the need of a high standard of technical education and proficiency is absolutely necessary on the part of the medical practitioner. It is far otherwise, however, with the nurse who is called upon to carry out his directions. Under such circumstances we are unable to recognise the need of registration, especially as the present system answers all practical purposes sufficiently well. Individual incompetence cannot be remedied by any amount of registration. The demand for nurses who are competent and desirable, both on individual and technical grounds, is insatiable. Will registration fill the gap? So far from doing so it will in our opinion merely substitute a complex and misleading system for one that is practical and, on the whole, satisfactory. We yield to none in our appreciation of the self-denial, the competence, the virtue, and the general fitness of the modern nurse for the arduous duties she has undertaken to perform. With every good wish for her present welfare and in all sympathy with her...
aspirations for the future we find ourselves unable to support any scheme for registration, at any rate with regard to arguments that have been hitherto forthcoming.

IMMUNISATION AGAINST TUBERCULOSIS.

The doctrine of immunity, both natural and acquired, against the various specific infections that may lay hold upon the living organism, together with the means by which such protection is obtained, is not of theoretical interest only, but is one which has been found capable of wide application in the domain of scientific medicine. It has given us vaccination, and in more recent times it has provided us with antitoxic sera, the use of which has succeeded in materially diminishing the mortality from certain of the acute infectious diseases. When we come to tuberculosis, the greatest enemy of the human race, the problem seems to become more difficult of solution. From the time of Koch's original discovery of tuberculin many devoted workers have given up their whole lives in the search after some agent which should confer protection against the ravages of the tubercle bacillus and also enable the organism when once infected to destroy the invader. The process of artificial immunisation of an animal against tuberculous infection was first successfully accomplished by Professor Maraglino, of Genoa, in 1895, who announced his results to the Congress of International Medicine then held at Bordeaux, and more recently to the International Congress at Madrid. In the early part of the present year, Behring, of Vienna, confirmed in the calf what Maraglino had stated eight years previously—viz., the possibility of "vaccinating" or rendering immune, animals against tuberculosis. The Genoese observer has animals in his laboratories which have been immune for as long a period as five years by submitting them to injections of serum from other immune animals. In the former an increase in the agglutinative power of the blood and also a greater development of antitoxins was noticed. The question naturally arises if such methods are applicable in any way to man, and, indeed, Professor Maraglino has been engaged in considerable experimental work in connection with this aspect of the subject. Evidence is forthcoming that injections of the serum of immune animals into a healthy man cause the development within his organism of certain defensive elements which lead to the conclusion that some degree of immunity against tuberculosis is thereby conferred. The instance is quoted of a tuberculous family attending the Polyclinic at Genoa in which seven of the children who all showed varying degrees of pulmonary tuberculosis were treated by progressive antitoxin injections and after eight years had elapsed were in excellent health, the pulmonary symptoms having disappeared. Behring has also found that the defensive materials of cows rendered immune in this manner pass into their milk, but only in small quantities. In contrast to this method of passively immunising animals there is the other possibility, namely, that of artificially producing active immunisation, a kind of "vaccination," as it were, against tuberculosis, which is preferable to the passive variety, since it causes the organism to react to a much greater extent and the protection afforded is more lasting. Professor Maraglino recalls to mind the clinical fact that a person completely cured of a localised pulmonary tuberculous focus generally remains insusceptible thereafter to tuberculosis. If it be possible, therefore, to produce a localised area of tuberculosis upon the surface of the body it may be expected that when this heals a degree of immunity will have been conferred upon the individual. And this is what has been accomplished in several cases, first in animals, and finally in the human subject. Though this method can hardly be considered to have passed beyond the experimental stage, yet it is a definite advance in our knowledge of the ways and means of combating the greatest scourge of the human race.

A MOTLEY-MINDED CRITIC.

Mr. Stephen Coleridge reminds us of nothing so much as the Cartesian diver; no sooner is he submerged than up he pops again as though nothing had happened. To be sure, the process has never been tried in too deep a bottle, or, like the figure in Descartes' little experiment, he might not rise again. This, we think, would be a pity, for surely no more ingenuous humorist has ever posed before the public. Kicks and cuffs seem to stimulate him to greater efforts and logical annihilation seems to be his intellectual Nirvana. Like the British Tommy, he never knows when he is beaten. Nor do we desire that he should awaken to the fact, for the gaiety of nations is not so pronounced at present that we can afford to dispense with one never-failing contributor thereto. All we would ask is that Mr. Coleridge should not take himself so seriously; he would be so much more entertaining if he doffed the mantle of the prophet and frankly donned the cap and bells. Besides, how much greater scope would he have for his inimitable talents! We are moved to these reflections by the appearance once more in the columns of some of our lay contemporaries of one of those periodic effusions that emanate from the National Anti-Vivisection Society's offices in Victoria Street. The only fault that we find with the document as a piece of perusiflage is that it so closely resembles those that have gone before; we must warn Mr. Stephen Coleridge that his position as a humorist will be seriously compromised if he continues to serve up "chestnuts," however artfully disguised. The particular cause of Mr. Stephen Coleridge's epistolary appearance at this juncture is the publication of the Registrar-General's returns for 1901. In these he has unearthed some startling facts. In 1891—before antitoxin was employed in the treatment of diphtheria—the death-rate from that disease was 173 per million in England and Wales; in 1901—after antitoxin had been widely used for six or seven years—the death-rate from the same cause was 273 per million. The
death-rate for croup, "for which," as he says, "fortunately, no serum was used," stood in 1891 at 97 per million; at the end of two years it was only 25. What more convincing evidence could be adduced of the beneficial effect of antitoxin? It is all so clear, so transparent, to anyone whose mind is not prejudiced by "vivisection" prepossessions and preconceived notions of the value of serum-therapy! We will not be so heartless as to point out that whereas the rise in the incidence of diphtheria in the community has been enormous, the case-mortality has fallen nearly two-thirds in the ten years under notice, and that it is by the case-mortality and not by the gross death-rates that the results of the antitoxin treatment must be judged; nor that the reduction in croup-mortality is due to the improved diagnosis that transfers these very fatal cases to the diphtheria column. It would not be worth while to do so; it would not affect Mr. Stephen Coleridge's belief; it would look as though we were inappreciative of his efforts to amuse. Then he shows, by a masterly addition, that the death-rates from throat and respiratory diseases, "for the cure of which no serum was sold," fell from 3,993 in 1891 to 1,684 in 1901. We are not certain what this proves—except that Mr. Stephen Coleridge is unaware of the statistical fallacy involved in adding up "rates." If we showed him how to correct his results we might spoil his conclusions and produce an anti-climax, and that would never do. The discovery of glycogen, he tells us, was to pave the way to the total cessation of diabetes, whereas the death-rate from that disease has persistently risen, "culminating in 1901 in the highest ever recorded." We should not have thought it could have "culminated" in anything else; but as it has "culminated," we may now anticipate its normal decline. Had this not been so, the only thing we could have done to reduce the alarming mortality from this disease was obvious—forget all about glycogen, and let diabetes go on as it did before that unfortunate discovery. If we appreciate the force of these lessons we shall see in a moment the danger of studying cancer, and we shall not be wrong, for already the "concentrated attention of vivisectors" on cancer "finds its sinister reflection" in the fact that 2,784 more persons died of cancer and malignant disease in 1901 that in 1891. We tremble to think what result will follow the recent efforts of the Royal Colleges and the Middlesex Hospital if these well-meaning, but mistaken, people are not stopped at once. If cancer resents study in this perverse fashion, our only salvation lies in burying our heads in the sand and letting it die of neglect. As we have said, Mr. Stephen Coleridge's one drawback is that he takes himself too seriously. Most men, when they wish to join in a game, take the trouble to learn the rules, and find out what it is all about. Mr. Stephen Coleridge does not worry himself about such trifles. He goes to the wicket when it is someone else's innings; faces the bowler with the back of his bat; plays forward at a "Yorker."); and starts running when he is clean bowled. Well, it is his way of enjoying himself, and perhaps he does not do so much harm after all.

Notes on Current Topics.

The Perpetuation of Counter Prescribing. The Board of Inland Revenue has indirectly recently granted a new lease of life to the pernicious habit of counter prescribing. It was decided in the case of Ransom v. Sanguinetti that such titles as "Cough Mixture" or "Liver Pills" involved a liability to stamp duty, and consequently there was much lamentation among the speculative type of pharmaceutical chemist who deals in "probabilities and possibilities," as compounds which offer to the buyer a probability of injury with the possibility of benefit may be termed. Complaints were duly made by chemists and druggists to the Board of Inland Revenue, with the result that according to our contemporary the Pharmaceutical Journal, "chemists and druggists may congratulate themselves on the condition of affairs being virtually restored" to what it was before the decision in the above-mentioned case. It appears that the Board have consented to a non-imposition of stamp duty in the case of mixtures the composition of which has been published in any form in a recognised book of reference. This means, as our contemporary points out, that if the enterprising chemist sends the prescription of his "possibility" to the editor of the Pharmaceutical Journal the formula "will be published in the pages of the P. J. Formulary in such a manner that no one can identify it except the person who sent it." Yet what this means we can only guess, inasmuch as each formula appears in the columns of our contemporary with a number attached, and this number must appear upon the bottle offered for sale. On turning to the P. J. Formulary, we find that it is a menu gathering in which teething powders, complexion pills, little liver pills, female pills, and diarrhea mixtures mingle. The only thing now required from the complaisant Board is the right to affix the chemist's name without incurring liability or stamp duty, and then he will be able to compete on equal terms, or rather at an advantage, with Widow Welch's female pills, and such like. We cannot congratulate the Board of Inland Revenue on its complaisance, or our contemporary on the support they have afforded to the promoters of this scheme.

The Road to Ruin. The conditions under which medical men hold office in the Poor-law Medical Service are, we are glad to say, every day becoming wider known, with the result that there is no longer an eager rush of candidates once a post is declared vacant. A little more self-restraint on the part of a few members of the profession and the battle will be won, with the result that medical men will obtain, at all events, a living wage. The exploitation of the medical profession for the benefit of the rest of the community has been in the past and still is being carried to too great an extent. Everywhere the
well-known and praiseworthy practical sympathy which members of the medical profession more than any other class bestow on those whom they consider require it has had the not unnatural effect of making those who are not proper objects of charity desire to become so, so far as medical services are required. Apparently this desire is not limited to English clubs and Irish Poor-law guardians, but is to be found in other countries also. The following advertisement appears in the columns of the German *National Zeitung*—"The death of the district surgeon has rendered the post he occupied vacant. Those who may desire to offer themselves as candidates for the post are informed that the late surgeon received 200 kronen (£8 15s.) per annum from the Provincial Council, and 88 kronen (£4 13s. 6d.) from the District Committee. Further there is a beautiful residence situated in a romantic neighbourhood, and there is a mineral well in the vicinity. The place is within an hour's walk of three railway stations. Candidates must send in their applications within the next thirty days." This offers varied inducements to medical men to apply for the vacant post. One thing alone is needed, but unfortunately that happens to be the most important. Beautiful residences, romantic neighbourhoods, and even railway stations within an hour's walk can be done without, but the district surgeon must have the means of purchasing his daily bread.

### The Campaign against Tuberculosis.

The Local Government Board for Ireland are in the course of making a further attempt to spread a knowledge of the simple and practical steps that can be taken by the public to prevent the spread of tuberculosis. In view of the continued high death rate in Ireland from pulmonary tuberculosis they have decided to re-issue their circular letter of September 16th, 1901, with various posters and leaflets dealing with the prevention of tuberculosis. The fourth paragraph of this letter is, perhaps, the most important, and is the one to which the Board especially draw attention. In it, they point out the importance of educating the people to the best means of guarding against tuberculosis, and with this object they suggest that the local authorities should endeavour to enlist the sympathy and support of the clergy of all denominations, managers of schools, schoolmasters, and all persons whose duties bring them intimately into contact with the poor. They also suggest that these people should be requested to distribute copies of the leaflet issued by the Board entitled "Information for Consumptive People." The death-rate from pulmonary tuberculosis in Ireland in the year 1901 was 21'5 per 10,000, while at the other side of the Channel a death-rate of 23'4 per 10,000 in England and Wales in the year 1871, had been reduced to 12'6 in 1891. These figures show the necessity for taking, as the Board says, "prompt and sustained action" with a view to reducing the present terrible mortality. They also show that it is possible to effect a reduction. The efforts of the Board will meet with the most cordial approval and support from the medical profession, and, if only the Local Authorities can be induced to take up the matter seriously, a diminution in the present terrible mortality is certain to result.

### Lady Residents in Hospitals.

"A Hospital Physician" takes Miss Hickman's remarkable disappearance as a theme in the *Times* upon which to hang sundry discursive remarks on the propriety of appointing medical women to resident posts in general hospitals. We are not concerned to deny that much of the work is of a nature requiring such physical qualities for its easy and proper performance as to militate against the desirability of the appointment of women. This, however, is the only real objection, for the silly talk of propriety in this connection is the outcome of a morbidly sensitive imagination. Surgeons who see no objection to the presence of half a score of nurses in the operating theatre squirm at the sight of a female student, and loudly proclaim that a hitherto dormant sense of modesty has been outraged. There may be ultra-sensitive natures in either men or women upon which the responsibility weighs too heavily, but they are quite the exception, and this sense of responsibility deserves to be encouraged rather than denied. Many a young house surgeon takes them far too lightly after a time, and is apt to forget that he occupies a position of trust. If women are to take part in the profession of medicine they must do so on the same terms as their brethren. It is impossible to weed out the one class of undesirable cases, and if they be deprived of any part of the general experience it will be to the detriment of their skill, self-reliance and technical ability. It is idle to speculate on the ultimate cause of this most regrettable catastrophe, and it is ridiculous to make it the text of jeremiads in respect of the admission of women to the practice of medicine.

### Another Electric Belt Fraud Exposed.

Thanks to the enterprise of the Medical Defence Union, another pernicious fraud on the suffering public has been scotched. Last week one Lewis Baillees was charged with falsely holding himself out to be a registered medical practitioner in connection with the notorious McLaughlin Electro-Vigour treatment. The defendant's name had been removed from the *Medical Register* in consequence of a conviction for felony, and his diplomas had been withdrawn, yet he made free use thereof to defraud the public in which he had associated himself. It was shown in evidence that the belts, for which enormous sums were demanded, were absolutely worthless from a therapeutical point of view, in spite of the extensive publicity given to their mendacious claims in the advertisement columns of the *Times*. There was no defence, and the defendant was fined £25 with £20 costs. The profits on this business are, however, so enormous that no pecuniary penalties of this kind are likely to deter the proprietors from continuing to carry it on. It will probably be necessary to adopt the plan that has on previous occasions been resorted to with success—*viz*,
to bring up the question of obtaining money by false pretences. To charge ten pounds for a worthless belt cannot be anything but a fraud, but, unfortunately, the proceedings are very costly, and no funds are automatically available for their prosecution. No doubt this exposure will to some extent enlighten the public on the foolishness of attaching any importance to the blatant pretences of an American mountebank, but such a commerce is distinctly immoral, and it is a scandal that these impudent quacks should be allowed a free hand in this country.

Cesiotomy.

In various communications to medical journals during the last few years we have noticed this term used to describe the procedure now generally spoken of as abdominal section. The old-fashioned term "laparotomy" is sanctioned by usage and is generally understood, though it labours under the etymological disadvantage of signifying "loin-cutting," and cannot therefore be defended philologically as a designation for incision through the anterior abdominal parietes. If, however, we are to change it, let us at least adopt a term that is beyond cavil; for us cesiotomy seems open to grave objection. We believe the originator of the word was Mr. Bland-Sutton, who is quite a good enough biologist to know the peritoneal cavity is not the only representative of the celom in the body, and to use a term that is based upon the assumption that it is to court misunderstanding by unnecessary ambiguity. Any operation in which the pleura or pericardium was incised could be equally accurately described as a cesiotomy, for both these cavities represent in the adult the space formed by the mesoblastic splitting in the embryo. We protest, therefore, against the adoption of a term which violates convention without ensuring accuracy. We are no opponents of reform in nosology, and we should gladly welcome a good substitute for laparotomy, but we would rather "bear those ills we have than fly to others," equally grievous, and less generally understood.

A Conviction for Spitting.

October 13th, 1903, should be a date to be remembered by the National Association for the Prevention of Consumption. By their efforts the possibilities tor evil that lie in the "disgusting and dangerous habit of spitting"—as Professor Brouardel has called it—have attained a wide publicity. The attention of those in authority was thus directed to their powers to prevent it, and the London County Council promptly passed a bye-law to punish spitting on their tram-cars, as a first experimental instalment of what may reasonably be expected to follow. This bye-law came into operation a few months ago, and on the 13th inst. the first conviction was obtained. This, it may be hoped, is the first fruits of a movement which can do nothing but good, for it shows that enlightenment has already not only reached the Council chamber, but also the magisterial bench. The extent to which spitting in the streets prevails was remarkably demonstrated by some observations of Dr. Annett, of Liverpool, recorded in the Journal of State Medicine last August. In a slow walk of an hour's duration in the early morning, he counted in the thoroughfares of Liverpool a hundred and eighty-three masses of expectoration. In this computation he did not include exsalivations—if we may coin the term—but only masses containing palpable mucus. Knowing how rapidly sputum dries and leaves no visible evidence of its presence, this may give some faint idea of the enormous number of single acts of spitting that take place daily in the streets. The danger of the habit may be evidenced by the fact that 4'76 of the sputa thus casually collected contained tubercle bacilli. We cannot hope to completely eradicate a habit so deeply rooted in the nation, and in some cases so necesssary, we feel ourselves that its regulation is rather the point to aim at. Every person with a little bronchitis cannot be expected to carry about a receptacle for his expectoration, and we cannot advise that he should swallow the sputum. The best solution seems to us to lie in the public provision of spittoons, containing some liquid disinfectant, at short intervals in crowded streets. Persons not using these could be treated as people now are who use the public thoroughfare as repositories for the other dejecta of the body.

A Diagnostic Sign of Twin Pregnancy.

In thin women with lax abdominal parietes it is often possible to make out the presence of two foetuses, but in the absence of these favourable conditions the obstetrician often experiences considerable difficulty in distinguishing between hydramnios and twin pregnancy. A Russian physician calls attention to the fact that the differential diagnosis can be made by observing the height and degree of tension of the broad ligaments. In hydramnios the uterus assumes a globular shape, due to the presence of the contained fluid on the periphery, whereas in twin pregnancy the distension is usually more or less transverse, thus separating the layers of the broad ligament. Under ordinary circumstances the upper borders of the ligaments can be felt as two large cords attached to the lower parts of the sides of the uterus, but in twin pregnancy the folds are effaced so as to become imperceptible on palpation. It follows that if we can feel the rounded tense edges of the ligaments on a level with the umbilicus, this fact alone virtually excludes the possibility of twin pregnancy, even though the degree of abdominal distension suggests this diagnosis.

Ankylostomiasis in Miners.

Among the many dangers which threaten the lives of the workers in the bowels of the earth the newest one, so far as this country is concerned, is the nematode worm, the ankylostomum duodenale. This intestinal parasite has been prevalent for some twenty-five years among miners in certain parts of the Continent, where it first made its appearance in the case of the Italian workmen engaged in the excavation of the St.
Gothard tunnel, from whence, in course of time, it spread to Austria-Hungary and the Westphalian colliery district in Germany. The recent outbreak of the disease at the Dolcoath mine in Cornwall has been carefully investigated by Dr. Haldane, F.R.S., who has made his report upon the subject to the Home Office. It was most opportune that Dr. Court delivered a lecture upon the "Miner's Worm" before the Conference of the Miners' Federation of Great Britain, held at Glasgow. The onset of ankylostomiasis is frequently insidious, but when once its presence is recognised it can be cured with comparative ease. It is noteworthy that Dr. Le Neve Foster, in his "Reports on Mines and Quarries for 1898 and 1899," uttered a warning to British mine-owners to be on the look out for the appearance of the disease. Strict cleanliness is the key to the prevention of infection, but, for obvious reasons, this is very difficult to ensure among miners, who, as a rule, have no facilities for washing their hands when underground or for observing other sanitary precautions, such as boiling drinking-water, or for properly disposing of excremental matter. These difficulties are all enhanced when the employes are foreigners who cannot understand or see the necessity for sanitary rules. It is not expected that the disease will spread to any great extent in this country, and it is hoped that by proper means it will soon be eradicated.

Operation in Typhoid Perforation.

Obscurely tucked away in the Medical Supplement to the Metropolitan Asylums Board's annual report we find an interesting comment on the present phase of this interesting question. It takes the form of a bare statistical table summarising the results for last year of the operations performed in the Board's fever hospitals for the treatment of perforated intestinal ulcers in typhoid fever. In all, twenty-one operations were undertaken in fever hospitals; in twenty of these the patient died, in two he recovered. Except in two cases, the operations were all performed within twenty-four hours of the occurrence of perforation, most of them within the first twelve. Looking at the successful cases we note that one was operated upon six and a half hours from the occurrence of symptoms, and that, though peritonitis was diffuse it was in a very early stage; the other was not undertaken till after twenty-two hours had elapsed, but in this case peritonitis did not appear to be general (from the description). In all the fatal cases peritonitis was widely diffused. One case is recorded in which the abdomen was opened, but no perforation was found, either at the time or at the subsequent autopsy. We should much like to know if this was the only case in which this took place, as judgment of the benefits of this operation must necessarily take into account the risk patients incur of having the abdomen opened under the impression that they have perforated, when really they have not done so. We all know the immense difficulties the diagnosis of perforation presents before peritonitis has set in; and how easily this may happen. We would suggest that these cases might be collected in a separate table in next year's report, for what we desire, after all, is to arrive at the exact advantages that may accrue from the operation. Two successes for twenty-one operations gives a recovery rate of under 10 per cent., and one cannot forget that under purely medical treatment some recoveries from perforation do take place. Murchison estimates this to occur in 10 per cent. of all cases, and whilst we bear these facts in mind we must regard operative interference as still sub judice.

Cremation.

Sir Henry Thompson certainly deserves warm congratulations for the success that has attended his patient efforts to overcome the prejudices of the people against cremation. The attachment, both hereditary and religious, of our countrymen to earth-burial was so close that it needed years of constant education to bring them to see that any alternative was reconcilable with proper regard for the dead. Little by little prepossessions were removed and objections disposed of, and now thirty years after the movement was inaugurated we find crematories gradually springing up in various places, blessed by Bishops and supported by public men. Sentiment has to be tenderly dealt with, but it should not be allowed to hold undue rank when modern urban conditions are daily making the disposal of the dead more and more difficult to accomplish without risk to the living. An admirably arranged crematorium was opened by Sir Henry at Birmingham the other day, and in his opening speech he showed how the risk of undetected crime could be eliminated by its operations, one of the most patient arguments used by his opponents being thus rendered nugatory. Now that by the Act of last session, local authorities are empowered to erect crematories we hope to see earth-burial become more and more a thing of the past; and crematories become the regular mode of disposal of bodies. We hope, too, that it will lead to the satisfactory settlement of another urgent question, we mean death certification. In the practice of cremation the certificate becomes the final word on the cause of death, and we hope that this will lead to a far more efficient system of certification being introduced than that which now obtains.

Scotch Anti-Vaccinators.

It has often been adduced as evidence of the superiority in common sense of our Caledonian neighbours that the vaccination laws work with very little friction north of the Tweed. The Scotch Anti-vaccination League have, however, been very busy of late. They have been trying to gain access to the small-pox hospital registers in Glasgow, and this has brought them into collision with the Corporation. A long debate took place at the Council meeting on the subject, and it was finally resolved to refuse the request, but only by a majority of one. We must say that we think this a mistake. We know that much prac-
tical inconvenience might result from permission being granted, but refusal to inspect the registers makes it appear on the face of it that there is something to conceal. Now we know that there is nothing of the kind. By the last Vaccination Act (which applied only to England and Wales) it was ordered that all sanitary authorities should keep registers of the state of vaccination of persons admitted into small-pox hospitals, and that these registers should be public. With this we are quite in sympathy, as any suggestion of secrecy immediately leads to charges of "manipulating figures," and "cooking statistics," which are as offensive as they are untrue. The more freely the facts about vaccination are ventilated, and the more they are debated, the more likely is truth to be apparent. The best evidence against the objections of the anti-vaccinationists is to be found in the small-pox registers. Why should they be denied the opportunity of seeing the evidence at first-hand?

Health Congresses.

At last the local authorities are beginning to kick. The fashion of holding annual congresses has grown tremendously of late years, and the months of July and August keep municipal bodies all over the country busy in providing "entertainment" for the various learned societies that have been "invited" by them. The invitation, we need hardly say, is all the other way; the association or institute intimate that they will be very glad to accept an invitation if tendered. The most exacting seekers for invitations are to be found amongst the various public health bodies, and we are not surprised to hear that a petition is being got up and extensively signed, praying that the Sanitary Institute and Royal Institute of Public Health will hold their congresses together. If the advancement of sanitary science is the prime object of these annual junketings, there can be no doubt that this would be greatly subserved by the proposed amalgamation, and we hope that this, and not personal aggrandisement, is the moving element in the organisation of this reunion. We shall watch the result of the petition with interest, though we hardly expect it to bring about the desired effect. One of the institutes always provides such a "good time" for its members that we think they will be rather jealous of having their rivals share it.

Mr. Gladstone and Natural Science.

The publication of Mr. Morley's eagerly looked-for biography of Mr. Gladstone is the event of the book season. To us, in our professional capacity, these three bulky tomes have a peculiar interest—almost a negative one. It is paradoxical to think that this most eminent and versatile of statesmen should have acted as protagonist in nearly every movement of the last half of the nineteenth century, and yet have had no knowledge of the natural sciences, and practically no interest—even platonic—in them. A curious comment on the attitude of his mind towards things scientific that struck us particularly in reading Mr. Morley's book was his attitude to F. A. Wolf, one of the earliest of the modern school of scientific critics. Wolf's criticisms of Homer Mr. Gladstone dismissed as 'bubble-schemes,' and looked upon his methods as "chimerical and dangerous." Mr. Gladstone's conscience in medical and scientific matters, in the latter part of his life, he delivered for safe-keeping in the hands of Sir Andrew Clarke, who seems to have retaliated to him just so much medical lore as he thought fit on occasion. With this he seems to have been perfectly satisfied—a very striking fact in connection with one of the most naturally inquisitive minds ever fashioned. Medical art he regarded as akin to the uncanny, and natural phenomena as mysteries into which it was not safe for plain men to probe too deeply.

A Tilt Against Specialists.

One wonders against what particular category of specialists Sir W. S. Church intended to direct the somewhat drastic remarks of which he delivered himself at his inaugural lecture last week at the West London Post-Graduate College. "A certain number of these so-called specialists," he tells us, were "no doubt honourable men," but no inconsiderable number, he opined, traded rather on the ignorance of the public than on any superior knowledge of their own. Even the good ones, he feared, had lost all sense of proportion owing to their having directed their thoughts exclusively to a limited range of subjects. There was a time still fresh in the memory of the present generation when specialists of every kind were the abhorrence of the regular physician, but we had thought that this prejudice had disappeared in deference to the conviction that specialism has become an indispensable factor in the progress of medical knowledge.

Lip Habits.

The habit of biting the lips so common in children, and analogous to that of biting the nails or picking the nose, admits of several explanations. It may be nothing more than an expression of nervous restlessness arising in the first instance from the desire to quell some peripheral irritation. In other cases the habit may be choreic in origin. The lip, like the tongue, is also bitten when the child wishes to check instantly some impulse which it recognises it would be harmful or disadvantageous to its own interests to carry out. During a momentary period of fright or strain the same movement is performed, probably from the idea that by so doing an added power of control or endurance is conferred, and it is for the same reason that a patient clutches tightly the arms of the dental chair previous to an extraction. At the thirteenth Congress of Mental Physicians and Neurologists of France, held at Brussels in August, M. Henry Meige, of Paris, exhibited a young man, aged 26, who presented a condition of multiple tics, such as constant sniffing, blinking of the eyes, knitting of the eyebrows, shaking the head, raising the shoulders, and kicking. The most curious thing about the patient was that the lips
were kept continuously open and were never brought into contact, even for speaking or eating. The lower lip was, therefore, never moistened by the saliva, and, in consequence, it was very dry, and in parts desquamating. The condition was described as “cheiophobia,” in contradistinction to the other habit, that of picking or biting the lips, and which is known as “cheilophagy.” Rhythmic movements of all kinds are common among the insane, while the many varieties of convulsive tics or habit spasms are more often seen in those in whom nervous control is weak or who come of a neurotic stock.

The Birmingham Children’s Hospital and Lady Surgeons.

The adoption by the Medical Board of a rule that all surgeons on the staff of the Birmingham Children’s Hospital should be Fellows of the Royal College of Surgeons of England entails—as was possibly intended—the exclusion of women from such posts. Against this decision a protest has been lodged on the ground that as women are not admitted to the fellowship the alternative qualification of M.S. of the London University ought to be accepted in lieu thereof. The recommendation was ultimately referred back to the Medical Board, not apparently with the object of appointing a lady surgeon, but in order to obviate an obvious injustice.

The Diploma of Apothecary.

The Association of Physicians and Surgeons of the Society of Apothecaries raises afresh the question of doing away with the archaic title of apothecary, in view of the fact that the licentiates of the Society have as much right to the title of physician and surgeon as the holders of diplomas of the Royal Colleges. The title of apothecary is now as obsolete as that of barber-surgeon, and no doubt it would be easy, under favourable circumstances, to substitute some more euphonious designation. For that, however, it will be necessary to await the introduction of an amending Medical Act, since it would hardly be practicable to obtain a special Act of Parliament. *De minimis non curat lex.*

A New Use for Old Railway Carriages.

Old railway carriages, like mankind, have their day and cease to be. It is somewhat pathetic to see these once fast-moving structures stranded in a country garden or serving as a shed by some desolate roadside. It would appear, however, that they may renew their dignity by hygienic adaptation. At the dinner of the Incorporated Society of Medical Officers of Health, Sir Wm. Church, President of the Royal College of Physicians, pointed out that at little cost old passenger coaches might be readily converted into admirable bungalows for consumptive patients. We believe that in certain places this has actually been done. When palatial structures are being reared for the housing of the tuberculous at enormous expense, and necessarily entailing great expenditure in satisfactory upkeep, it is well that people should be alive to the advantages of adopting simple means for securing satisfactory ends. This new use for railway derelicts is certainly deserving of attention.

Coffee as an Antiseptic.

As long ago as the beginning of the eighteenth century the virtue of coffee in time of plague was noted, and the opinion expressed that had it been known in England in 1665, it would have been found “of excellent use.” A hundred years later attention was drawn to the deodorising power of roast coffee, and its use was recommended to counteractbad smells of various sorts. In recent years, however, various scientific investigations have been made to define the degree of its bactericidal powers, and to discover which of the constituents of coffee possesses them. Luderitz, in 1889, showed that anthrax bacilli were killed by three hours’ exposure to a 10 per cent. infusion of coffee, and cholera bacilli by four hours’ exposure. Quite recently (b) Drs. Crane and Friedlander, of Cincinnati, have tried the preservative effects of ground coffee on various quickly decomposing substances. When mixed with egg yolk and white in the proportion of one to two, absolutely no putrefaction took place, although the substance was freely exposed to laboratory air throughout a hot summer. Chopped beef mixed with coffee also remained many months without the slightest sign of decomposition. It is not easy to decide to what constituent these properties of coffee are due, since green coffee is in no way antiseptic, nor has caffein any antiseptic qualities. The most likely hypothesis is that during the process of roasting coffee tannic acid gives rise to certain bodies resembling the phenols, but this is not yet established.

Granular Kidney in Childhood.

The rarity of chronic interstitial nephritis below the age of twenty is a clinical fact which is very soon learnt by the student of medicine. Nevertheless, cases of this disease have been known to occur in children of quite tender years, though, from the obscurity of many of the symptoms and the insidiousness of its onset, they frequently pass unrecognised. Dr. James Sawyer, in a valuable communication to the *Birmingham Medical Review*, has collected together twenty-four instances of this affection as found among children. The clinical histories of the cases appear to prove that the contracted kidney is not a late stage or sequence of the large white kidney; moreover, the specific fevers which play such an important part in the causation of tubal nephritis do not seem specially connected with this form of the disease. Male infants are often more affected than females. The question of the influence of syphilis is very fully discussed, and, having due regard to the clinical facts and post-mortem appearances, the opinion is given that the disease, whether congenital or acquired, is probably the chief factor in the causation of chronic interstitial

---

(b) *American Medicine*, September 5th, 1903.
nephritis in childhood. The morbid anatomy is practically identical with that of the adult form of the affection. The symptoms are those of increased arterial tension with cardiac hypertrophy, excessive thirst, and continued loss of weight. The onset is often indefinite, but convulsions, "night-terrors," vomiting, or urinary symptoms should lead to the suspicion of granular kidney, and a careful examination of the urine and of the heart at once undertaken. The presence of albuminuric retinitis, although a late manifestation, is regarded as a certain indication of the disease; it was, however, only recorded in three of the cases. The prognosis is very grave, and the treatment must be conducted on similar lines to that carried out in the adult variety of the malady.

The Late Miss Hickman.

After several weeks of agonizing suspense the mystery of Miss Hickman's disappearance from the Royal Free Hospital has been solved, at any rate, in so far as her actual fate is concerned. The discovery of her body, the identity of the remains having apparently been clearly established, in a copse in Richmond Park, puts a term to idle conjecture which will now be reserved for the reasons and details of the unfortunate lady's fate. The sympathy of the profession and of the public will go forth to the parents bereaved of a distinguished daughter by such a terrible catastrophe. Professor Pepper has been instructed by the Home Office to examine the remains in order, if possible, to elucidate the cause of death, but the advanced state of decomposition will render the task one of unusual difficulty.

The Removal of King's College Hospital.

At a meeting held last week in the large theatre of King's College, the question of removing the hospital to a site in South London was carried by a large majority, after a somewhat prolonged discussion. Of the wisdom of this decision little doubt can be entertained, and it marks, let us hope, the commencement of an era of redistribution of medical charities. The present arrangement is productive of immense inconvenience to countless thousands of the suffering poor, and entails huge waste of funds.

The sudden death is announced of Mr. Lewis A. Tallerman, whose name is well known in connection with the local application of heat in the treatment of certain diseases of joints, &c.

The opening lecture in connection with the Winter Post-Graduate Course of the Mount Vernon Hospital for Consumption was delivered by Professor Thomas Oliver of Newcastle-on-Tyne, on Thursday, October 15th, the subject being "Occupation as a cause of Lung Disease."

Dr. G. B. Mason, Medical Officer of the Leeward Islands, left England on Wednesday last for the Colony.

Dr. C. J. Thomas has been appointed full time assistant medical officer to the London School Board at a salary of £400, rising to a possible £600.

Dr. T. L. Anderson has been deputed by the Government of Western Australia to proceed to India, to investigate and report on the plague operations in force in that country.

A public meeting of the Senate of the Royal University of Ireland will be held on Friday, October 22nd, at 3 p.m., for the purpose of conferring honorary degrees on T.R.H. the Duke and Duchess of Connaught.

The medals and prizes awarded at the termination of the previous sessions in the Schools of Surgery of the Royal College of Surgeons in Ireland, will be presented by Sir Lambert Ormsby, President of the College on Monday, November 2nd.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

[FROM OUR SPECIAL CORRESPONDENTS.]

SCOTLAND.

EDINBURGH UNIVERSITY EQUIPMENT.—During the past summer a number of improvements in the pathological chemical, and anatomical departments of the university have been made, which will go far to keep it abreast with the times as a teaching institution. The chemical laboratories were originally designed for forty students (in addition to those attending the regular practical class of the medical curriculum), but from various causes the number desirous of attending, whether to learn chemistry as applied to assaying, brewing, or simply to acquire that practical knowledge of chemistry now demanded of teachers in public schools, has increased so greatly that the laboratory has had to be extended so as to admit of its taking nearly a hundred students. Sundry minor improvements have also been effected as to lighting, and a high pressure water supply has been laid on in the laboratories. In the pathological department a large new bacteriological class room has been opened, which will accommodate fifty students. Space has been got for it (as was done in the new chemical laboratory) by lowering the roof of an already existing class-room and utilising attics. There is a complete installation of Nernst electric lights at the tables, and each student has a separate Bunsen. In the new equipment of the laboratory forty new microscopes, all provided with immersion lenses, have been required; there are also incubators, &c., and an electric centrifuge. The old bacteriology room has been converted into a research laboratory. The histological class-room has had Nernst lamps substituted for gas, and arrangements have been made for the extensive employment of photo-micrographs and projector lantern in teaching instead of the old-fashioned diagrams. The chief improvements in the anatomical department consist in the introduction of the electric light, and improvements in the ventilation and warming of the dissecting-room. In this department, too, diagrams will be largely superceded by photographs, and a complete plant similar to that in the pathological department has been laid down. A scheme of library extension is now going on, the object being to house the present books and those which are constantly being added, in space which is now full to overflowing. The problem is being solved by the substitution of improved library standards and shelves made of steel, for the present wooden erections. Only one room so far has been completed, and in a space 23 ft. by 22 ft. by 20 ft. high, shelving
which will contain 45,000 volumes has been erected. The work is being done by the Art Metal Construction Company of New York. In reconstructing the base- ment of this part of the university a large, commodious cloak room for women students, communicating with their reading room has been made.

RE-OPENING OF THE SCOTTISH MEDICAL SCHOOLS.—Though some of the practical classes have been in progress since October, the existence of the lectures did not begin till the 15th. As a rule the form of a special introductory address was dispensed with, and the work of the winter began without prejudice. The new professorship at Edinburgh has covered its inaugural address in the Macewen Hall to a large body of students and a considerable sprinkling of the general public. The principal part of Professor Cunningham’s remarks was devoted to the history of anatomical teaching in Edinburgh from its foundation in 1607, when, through the efforts of the College of Surgeons and Town Council, an anatomical theatre was built. In 1705, Mr. Elliot was appointed public prosecutor, and received also a small salary from the Curiators of the University, thus becoming first professor of anatomy. The first real teacher, however, was Monro primus (1720), and around his chair other departments of medical study grouped themselves to form the beginnings of the medical school. Describing the influences at work in the seventeenth century, the speaker pointed out that Marlowe’s campaigns caused an unusual demand for army surgeons; the navy and navy, and the practical training in anatomy were for these a matter of supreme importance. That no doubt had its influence in Edinburgh, but other circumstances weighed more, and among these was the intercourse between Scotland and England, while heathen schools reigned supreme. Having glanced at the holders of the chair from the three Monros down to Goddard and Sir William Tynney, the lecturer concluded by a consideration of some general points in connection with anatomy.

The winter session of St. Andrew’s University was opened by Principal Donaldson’s address, which chiefly dealt with the operations of the current academic year and the condition of the University, a benefaction of which it was absurd to say that it would undermine the independence of the students.

At the University of Aberdeen, Professor Terry gave an inaugural address on his appointment as Professor of History, in the course of which he pleaded for the foundation of a central school of historical method and research, by which the efforts of these historical miners, the Carnegie Research Fellows and scholars, might be directed and stimulated.

SCOTTISH SOCIETY OF THE SONS AND DAUGHTERS OF MEDICAL MEN.—A circular has just been issued to medical men in Scotland requesting their assistance in the formation of a benevolent society under the above title. The names on the list of the Provisional Committee consist of both lay and medical men, and are such as to ensure that the society will start under the most favourable auspices, and wise guidance. The object of the circular is to get all the names of sons, daughters, and grandchildren of medical men in Scotland, when the Committee propose to approach them and induce them to become members so that the object of the society is entirely benevolent, in the way of affording pecuniary and other assistance to the widows and children of medical men. The life subscription is £1 18s., or any greater sum. If only a quarter of the descendants of Scottish medical men would become members of this society, the aim of the Committee—to rival the prosperity of the societies of the sons and daughters of the ministers of the Church and of the laity—would be readily attained.

ANNUAL DINNER OF THE SOCIETY OF THE SCOTTISH MEDICAL MEN.—This dinner took place at the Grand Hotel, Charing Cross, on the evening of the 15th inst., when over sixty gentlemen sat down to what proved to be a capital dinner. The president of the society, Mr. Thomas Richmond, L.R.C.P.E., occupied the chair, Mr. A. R. Maylord and Dr. Thos. Forrest were

croupiers. A telegram from the hon. president, Sir J. Halliday Croom, Edinburgh, was received, regretting his absence through illness. Letters of apology for absence were also read from Sir Samuel Chisholm, Bart., and Councilor Kirkpatrick. The usual loyal toasts having been proposed, and enthusiastically responded to, the toast of "Our Society" was proposed by the chairman, who was reminiscent of the early days of the society’s formation, when its members were few, and how it had gone on growing and prospering till it had attained to a membership of 238 at the present time. The other toasts included "The Imperial Forces," by Mr. A. E. Mayland, and replied to by Brigade-Surgeon Lieut.-Colonel Corrie; "The Glasgow Medical School," proposed by Dr. James Erskine, and replied to by Mr. H. E. Clark and Dr. Renton; "Our Guests," proposed by Dr. Edington, and replied to by Professor Murtoch Cameron and Mr. John Henderson. "The Chairman," proposed by Dr. C. E. Robertson and briefly replied to by the Chairman. The enjoyment of the evening was enhanced very materially by the playing of an orchestra and songs contributed by Professor Cameron, Drs. T. K. Monro, and Wauchope, Mr. Ingram, Mr. Marshall, and the Chairman.

BELFAST.

ARMAGH ASYLUM.—At the monthly meeting of the Board of this asylum, it was reported by the Inspector of Asylums that the population of the asylum at the date of his visit was 501, only four more than at his previous visit, but unfortunately the inmates had kept down from want of room, all but the most urgent cases being refused admission. The estimated accommodation of the asylum was for 434 (214 males and 220 females), while the average number kept during the year was 225 males and 204 females. The percentage of deaths during the year was 27½ votes, or 107 among the males and 44 among the females. The average cost of maintenance during the year was £28 16s. 4d. Handicapped by the occupation of the inmates were about to be introduced, having already been successfully introduced in six other county asylums.

BELFAST STUDENTS AT THE ROYAL UNIVERSITY.—The results of the degree examinations at the Royal University, which were published last week, have given rise to very considerable dissatisfaction here. Of the forty-seven students who presented themselves at the final examination, only twenty-threethree passed a couple of these only nine were Belfast men, a decidedly smaller number than usual. It appears to be the surgical examiners who have specially offended on this occasion.

Correspondence.

QUACKERY AND THE LAW.

To the Editor of The Medical Press and Circular.

SIR,—To the medical man of the world, and having his eyes fairly well open to what is going on around him in the domain of fraudulent quackery, the exposure of the internal economy of an “electrical belt establishment” made at Bow Street Police Court on Tuesday, October 13th, can cause neither surprise nor retribution. Perhaps twenty-three have been caught, but why call forth your editorial comment. I would like to direct attention to a few particular points. In the first place, it is to be remarked that the prosecution was initiated by a person in the Civil Service, and that the Union is an association of members of the profession, having no obligation to act as guardians of the public against quackery. The motives of its action in the case in question 1, for one, am at a loss to account for. Mr. F. Henderson, 166, Buchanan Street, Glasgow, is inter- nal secretary and treasurer of the society.

ANNUAL DINNER OF THE SOUTHERN MEDICAL SOCIETY.—This dinner was held at the Grand Hotel, Charing Cross, on the evening of the 15th inst., when over sixty gentlemen sat down to what proved to be a capital dinner. The president of the society, Mr. Thomas Richmond, L.R.C.P.E., occupied the chair, Mr. A. R. Maylord and Dr. Thos. Forrest were
gentleman ready to purvey the marvellous electrical apparatus described in court. The Medical Defence Union went out of its way to prosecute in this case; and if no private association of the kind takes upon itself such an invidious duty, proceedings to enforce the Medical Acts are impossible. The General Medical Council has no power to interfere; no public prosecutor is present to urge the discretion of the penal clause. The Medical Act are consequently almost entirely dead letters. Then, again, the man was not charged with any offence relative to the actual trade he was carrying on. In this he is not amenable to the law as it is at present construed. For he is left self amenable; his sole offence legally was the assumption of forfeited titles. Lastly, the case serves to enforce the suggestion lately put forth in your correspondence columns, namely, that there ought to be appointed a Royal Commission to inquire into the whole subject of unqualified medical practice and quackery, including the manufacture and sale of quack medicines. Such an inquiry would prove and make plain that legislation directed against fraudulent quackery of every kind, although it might do something to improve the advantage of the medical profession, would do a thousand times more for the stupid, ignorant, or too cunning masses and suffering mankind an easy prey to cynical knavery. It will be necessary to bring these facts home to the minds of our legislators before the smallest chance for acceptance of any project of medical law can be created.

At present, proposed medical legislation of the kind is looked upon as a trades' union move for selfish ends by the doctors. Everyone who knows anything about the history of medical legislation must recognise that without the education in the question which Members of Parliament almost entirely lack, no House of Commons will listen with patience to a Medical Act Amendment; and I venture to apprehend that the Bill of the British Medical Association now in process of preparation be presented without this preliminary action I suggest, it will have not the smallest chance of acceptance at all, as it may be, by the united voice of 20,000 qualified medical practitioners.

I am, Sir, yours truly,

H. S.

SPECIALISM.

To the Editor of The Medical Press and Circular.

Sir,—It seemed to me, when reading the report of the address by Sir Selby Church at the opening of the Post-Graduate College, the remarks made by him on the subject of specialism were not such as one might have expected. It has always appeared to me important to recognise the necessity for specialism in certain kinds of professional work, and those kinds are where technical skill and special training in such are required. Now, technical skill is far superior to general hand above all things, where practice, particularly where delicate manipulation, comes in, and is absolutely necessary. We recognise specialism in the diagnosis and treatment of disorders of the eye, the ear, the throat, and some other organs. When we come to the treatment of diseases such as fevers, tuberculosis, cancer, and others which are not limited in their influence upon one organ, and where technical skill is not so important as a knowledge of the nature of the malady we are dealing with, specialism is not possible, or at least not of much advantage. It has always appeared to me a very doubtful matter whether specialism in lunacy is of any good. I would rather have the opinion of a good practitoner in a lunacy case than that of a specialist. Specialism we find was generally indulged in, and cultivated, in the histories of ancient peoples, among the Egyptians, Greeks, and at times when they were beginning to degenerate and retrograde. Specialism was a bad sign, and always will be of the social condition of a people when it begins to grow up, nor need we wonder Sir Selby Church is evidently not in favour of too much specialism, but what is proper specialism and what is not he does not seem to have considered and understood.

I am, Sir, yours truly,

Non-Specialist.

SIR GEORGE DUFFEY, M.D.

We deeply regret to have to record the death of Sir George Duffey, M.D., at his residence in Fitzwilliam Place, Dublin, after a prolonged illness. Sir George Duffey was one of the best known of the Ex-Presidents of the Royal College of Physicians, which office he had held in the year 1864. In the use of his post he was most efficient. A recent date he held the post of Visiting Physician to the Royal City of Dublin Hospital, and in our present issue we chronicle the fact that during the past week the Governors of the Hospital had conferred upon him the post of Consulting Physician. The late Sir George Duffey had a varied career, and an acquaintance with more sides of medical life than is permitted to most men. He was not only a very celebrated graduate, having taken a medical scholarship and a senior medical exhibition. Soon after obtaining his M.B. and M.Ch., he entered the Army Medical Service, becoming attached to the 24th Regiment. During his stay in Malta with his regiment, he made his valuable contribution on Mediterranean fever, to medicine, and pointed out the advisability of army medical officers studying the local diseases of the stations at which they are on duty. This contribution was the forerunner of many excellent papers, all of which are of a practical character. We may but enumerate a few of the many: "Cystic Degeneration and its Degeneration in the Kidneys"; "Rheumatic Orchitis as a Sequel to Fever"; "On the connection of acute Diabetes with Disease of the Pancreas"; "Hydatid Cyst of the Pleura"; and "Laryngeal Nystosis in Erysipelas". We select these from among his many papers, all of which are
valuable, because they show the author's keen power of observation and his wonderful patience in working from the ground up. As a physician and a surgeon he possessed the same quality of medical mind that made Addison and Anstie great. No personal trouble was too great, no grind or toil was too heavy, where a patient's life was at stake. And in all his attendances no word escaped his lips towards his patient but those of kindness and hope. In the presence of sickness all the best qualities of the man were shown—thoughtful, courteous, kind, every patient loved and trusted him. In 1872 he resigned his commission and settled in Dublin. About this time he turned his attention to journalism for a short time, and founded and managed the Irish Hospitals Gazette, a small journal which was afterwards merged in the Dublin Journal of Medical Science. In 1876 he was appointed physician to Mercer's Hospital, and lecturer on Materia Medica in the Carmichael School of Medicine. He maintained his connection with Mercer's Hospital until, in 1882, he was appointed physician to the City of Dublin Hospital, and his lecturership, until, on the amalgamation of the Carmichael and the Leducch Schools of Medicine of the Royal College of Surgeons, he was appointed to the professorship of Materia Medica and Pharmacy. During a particularly active life Sir George Duffey held many other posts of which the following were the most important:—Examiner in Medicine in the Queen's University before its dissolution; Extern Examiner in the Institutes of Medicine in the University of Dublin; Inspector of Examinations for the General Medical Council, and Visitor for his Majesty's Privy Council in Ireland; Examinations of the Pharmaceutical Society of Ireland.

Sir George Duffey's connection with the Royal College of Physicians was long, intimate, and characterized by the most friendly relations with his colleagues. In 1873, just thirty years ago, he was elected a Fellow of the College, and in 1896 he was chosen to be President for the first time. He was re-elected in the following years, again on the occasion of the Jubilee of her late Majesty, Queen Victoria, received the honour of knighthood.

Sir George Duffey's death at the comparatively early age of sixty is a loss to many beyond his own immediate family circle. He will be long remembered as a warm-hearted and sympathetic medical man, as a powerful and constant supporter of the dignity of his profession, and of the college in whose councils he for so many years assisted, and as a most faithful friend.

Medical News.

The Meath Hospital, Dublin.

On Monday, October 12th, a very large meeting in connection with the Winter Session of the medical school attached to the Meath Hospital and County Dublin Infirmary was held in the hospital, and attracted a very large attendance. The chair having been taken by Sir Francis Cruise, M.D., F.R.C.P.I., Sir Philip Smyly, Surgeon-in-Ordinary to the King in Ireland, delivered the inaugural address. Since the last time he had opened the session there had been many changes. One of the most serious was the death of Sir William Stokes, a true friend, a true gentleman, and a distinguished surgeon, who gave up his life in the service of his Queen and country, but not until he had made a great reputation for himself, and perpetuated the reputation of his father, William Stokes, who, with Graves, made the Meath Hospital famous all over Europe. To the earnest and active co-operation of Sir W. Stokes was due in no small measure the new operating theatre in the hospital, where there was every contrivance to enable surgeons to practise aseptic surgery. Having briefly referred to the esteem and respect in which the late Mr. Patterson, a member of the staff, was held, Sir Philip having paid tribute to the brilliant work of Dr. Freyer, an Irish surgeon now practising in London, and a member of the Irish Graduates' Association, to which every Irish medical man should belong, the speaker referred to the two great subjects which were interesting both to the profession and the public—tuberculosis and smallpox. At the close of the address Dr. Little proposed a vote of thanks to the lecturer, who deserved warm commendation for the excellent quality of his address. The motion was seconded by Dr. Wallace and seconded by Dr. Waller, both of whom were passed by acclamation. Sir Francis Cruise having suitably responded, the proceedings terminated.

Society for Relief of Widows and Orphans of Medical Men.

A QUARTERLY court of the directors of the Society was held on Wednesday last, the President, Mr. Christopher Heath, F.R.C.S., in the Chair. Three new members were elected, the death of a member was reported, and the resignation of a member accepted. The death of a widow, aged 87, who had been receiving £50 per annum since May, 1890, was announced. Applications for assistance were read from three orphans of a member who died in 1890, and grants at the rate of £12 per annum made them. Applications for renewal of grants were read from fifty-three widows, sixteen orphans, and four recipients from the Copeland Fund, and £1,321 were distributed among them at the next Court, subject to the report of the visitors. It was resolved to make the usual present at Christmas to the widows and orphans on the funds, viz., £10 to each widow, £3 to each orphan, and £5 each to the four orphans on Copeland Fund, in all £89. The expenses of the quarter were £65 14s. 6d.

Royal City of Dublin Hospital.

The Board of this hospital have appointed Sir George F. Duffey, M.D., Consulting Physician (since deceased), and Mr. Henry Fitzgibbon, F.R.C.S., Consulting Surgeon to the hospital.

Gordon Defence Fund.

A MEETING of the Committee of the above took place at 92, Merrion Square, Dublin, on Friday last, October 16th, Sir Lambert H. Ormby, President of the Royal College of Surgeons, in the Chair. Dr. Andrew Horne, hon. treasurer of the Fund, reported that a sum of £96 7s. 1d. had been subscribed and deducting expenses it was arranged that a cheque for £91 7s. 4d. be handed to Dr. Alexander Gordon, Rathmines, to assist him to pay the law expenses connected with the maintenance of a case of blackmailing of which he was the victim. As all members of the profession are liable to be assailed by these unfounded charges it is gratifying to learn that the profession in Dublin have so promptly responded to the appeal sent out by the presidents of the two Royal colleges, and which was originally started by the editor of the Medical Press and Circular in these columns. Dr. R. S. Wayland, F.R.C.S.I., kindly came to the aid of the Fund and gave such assistance in bringing this Fund to such a satisfactory termination.

Conjoint Examinations in Ireland.

London School of Tropical Medicine.

The entry of students at the London School of Tropical Medicine (Mr. Chamberlain's scheme for improving the health of the tropics) is now open to the public.—In the London journal of Medical Science. About thirty past graduates have already joined for the autumn session, nearly half being sent from the Colonial Office, Foreign Office, and Indian Medical Service.
Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and to avoid the practice of signing themselves "Reader," "Subscribers," or "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side only, and should be authenticated by the name and address of the writer, not necessarily for publication, but as evidence of identity.

References.—Reprints of articles appearing in this journal can be had at a reduced rate by providing authors by enquiring to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Post-Graduate (Leeds).—Although Woollong, presumably mainly owing to the excellent train service provided by the London and South Western Railway, is fast becoming a large and important provincial centre, we understand that it is already amply supplied with medical men. Still, possibly it would be worth our correspondent's while to visit the locality and personally to make inquiries on the spot.

Ruricape.—In our opinion our correspondent would be well advised to allow the matter to rest where it is.

Provincial Syrcon.—Despite the fact that there are now two actual vacancies on the surgical staff of St. Bartholomew's Hospital, and the constant year by year to the termination of office of Mr. Langton, it is unlikely that the authorities will look elsewhere than in their own school for candidates to fill the posts. The post of medical officer of health for the district will, no doubt, elicit the information our correspondent requires.

ALPHA.—The late Mr. W. J. Walsham was not a member of the Council of the Royal College of Surgeons. He succeeded, unsuccessfully, about two years ago.

Tu Quoque.—Our correspondent will note that we deal with the matter editorially in the current issue.

B.—The terms of the agreement are very clear, and however hardly they may press upon you, we believe they could be enforced. The post which he desires apparently conscientiously consults as solicitor or one of the medical officers.

De R. (Sheffield).—A patient has a legal right to demand the details of the procedure by which the diagnosis is arrived at, and of obtaining in a mere statement of indebtedness. Any hesitation in acceding to such a request on the part of a practitioner might be misunderstood and should be avoided.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, October 8th.

Royal Microscopical Society (58 Hanover Square, W.).—8 p.m. Mr. G. D. Scott: Exhibition of Drawings and Slides of British Hyphal Hyphae.—Paper; Mr. F. W. Mullett: Report on the Recent Formulations of the Malay Antillogel, Part IV. Medical Society (University College, London).—8.30 p.m. Address to the Licentiates: Logic and Reasoning.

Post-Graduate College (West London Hospital, Hammersmith Road, W.).—5 p.m. Mr. R. W. Lloyd: The Administration of Anesthetics. (First Lecture.)

THURSDAY, October 9th.

Post-Graduate College (West London Hospital, Hammersmith Road, W.).—5 p.m. Mr. E. Clayton—Burlington (Second Lecture).

Montoy Venereal Hospital for Consumption and Diseases of the Chest (7 Fitzroy Square, W.).—5 p.m. Dr. Bernard O'Connor: Practical Diagnosis and Treatment.

FRIDAY, October 10th.

Clinical Society of London (20, Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 p.m. to 10 p.m.

Post-Graduate College (West London Hospital, Hammersmith Road, W.).—5 p.m. Dr. Abraham—Skin Cases.

Appointments.

BoYDOTT, A. E. M., M.Ch.Oxon., Gordon Lecturer in Experimental Pathology to Gloucester General Hospital.

Edward, Robert Thor, M.R.C.S., L.R.C.P., Resident Medical Officer to the Aberdeen Infirmary and the Carstairs General Hospital.

Mould, G. W., M.R.C.S., L.R.A., Consulting Medical Officer and Superintendent of the Welsh houses connected with the Royal Asylum, Chandl.

Mould, Philip G., M.R.C.S., L.R.C.P.Lond., Second Assistant Medical Officer to the Royal Asylum, Chandl.

Scurfroy, Harold, M.D.Edin., Medical Officer of Health for the City of Sheffield.

STIFF, H. H., M.B.Cantab., Certifying Surgeon under the Factory and Workshops Act for the Bury St. Edmunds District of the County of Suffolk.

Birkhead, John, M.R.C.S., L.R.C.P.Edin., Senior Assistant Medical Officer, Royal Asylum, Chandl.

Vacancies.

Birkhead Union.—Resident Assistant Medical Officer. Salary £150 per annum, with board, washing, apartments. Applications to Mr. John Carter, Clerk's Office, 45 Hamilton Square, Birkhead.

Brighton Sussex County Hospital.—House Surgeon. Salary £150 per annum, with board, and residence in the hospital. Applications to the Secretary.

British House and Hospital for Incurables, Streatham, S.W.—Medical Officer. Salary £150 per annum. Applications to the Secretary.

Chelsea Infirmary, Isle Street, S.W.—First Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, coal, gas, and washing. Applications to the Clerk to the Guardians, 250 King's Road, Chelsea.

City Asylum, Gosforth, Newcastle-upon-Tyne.—Assistant Medical Surgeon. Salary £150 per annum, with board and lodging in the Institution. Applications to the Secretary, 13 Dassell Terrace, Darlington.

Glasgow District Asylum, Woodside, Lesmahagow.—Junior Assistant Medical Officer. Salary £100 per annum, with board, washing, &c. Applications to Dr. Marx, Medical Superintendent.

Glasgow District Asylum, Woodside, Lesmahagow.—Salary £100 per annum, with board and residence. Applications to Mr. A. F. Kirby, St. Peter's Church Hall, Nottingham.

Glasgow General Hospital.—Assistant Medical Surgeon. Salary £100 per annum, with board, lodging and washing in the Hospital. Applications to the Secretary.

Glasgow General Hospital.—Resident House Surgeon. Salary £100 per annum, with board, lodging, and washing in the Hospital. Applications to the Secretary.

Glasgow General Hospital.—Resident House Surgeon. Salary £100 per annum, with board, lodging and washing in the Hospital. Applications to the Secretary.

Royal South Hants and Southampton Hospital.—House Surgeon. Salary £100 per annum, with rooms, board, and washing. Applications to Mr. A. Fisher Hall, Secretary, Royal South Hants and Southampton Hospital.

The Royal Asylum, Chandl., Cheshire.—Third Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, &c. Applications to W. Scowcroft, Medical Superintendent.

The Royal Asylum, Chandl., Cheshire.—Second Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, &c. Applications to W. Scowcroft, Medical Superintendent.

The Royal Asylum, Chandl., Cheshire.—First Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, &c. Applications to W. Scowcroft, Medical Superintendent.

The Royal Asylum, Chandl., Cheshire.—First Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, &c. Applications to W. Scowcroft, Medical Superintendent.

The Royal Asylum, Chandl., Cheshire.—First Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, &c. Applications to W. Scowcroft, Medical Superintendent.

Wolverhampton and Staffordshire General Hospital—House Physician. Salary £150 per annum, with board, lodging, &c. Applications to E. Forster, House Governor and Secretary.

Deaths.

Fry.—On Oct. 10th, at 44 Rochdale Road, Rochdale, Mrs. Sherlock (nee Longstaff), aged 75 years.

Drexel.—On Oct. 16th, at 25 Leamington Gate, Hyde Park, the wife of Alfred R. Drexel-Taylor (nee Dean), aged 71 years.

Duce.—On Oct. 14th, at High Beach Road, Loughton, Essex, the wife of Percy Duce, M.R.C.P.Lond., of a son.

Marrages.

EDMUNDS—BUTCHER.—On Oct. 15th, at St. Mary and All Saints', Chesterfield, Flavel Edmunds, M.B., Ch.B., of L.M.C.P.E., second son of the late Wilfred Edmunds of Chesterfield, to Miss Kate Orton, daughter of the late M. B. Butcher, and of Mrs. Turner, Rose Hill, Chesterfield.

McNeight—HALLAM.—On Oct. 14th, at the Parish Church, St. Michael and All Angels', Northchapel, Sussex, William Robert Percival McNight, M.A., M.D., T.C.D., eldest son of William J. McNeight, Esq., of Howth, co. Dublin, to Kathleen Mary, eldest daughter of the late Colonel and Mrs. Halkam, of Sandhurst, Chiddingfold, Surrey.

Perry—CROWDER.—On Oct. 14th, at Muswell Hill Baptist Chapel, T. Hayes Perry, only son of the late Thomas H. Petch, M.D., of Battersea, to Ada Beatrice, youngest daughter of the late Robert Reynolds Crowder, of Warrington, and Mrs. Crowder, of Muswell Hill, N.1.

Sept 30th to Oct 6th, 1903.
FOREIGN CLINICAL LECTURES.

THE ORIGIN OF MALIGNANT NEOPLASMS.

By Dr. F. DE QUERVAIN,
Surgeon to the Chaux-de-Fonds Hospital and Lecturer on Surgery to the Faculty of Medicine of Berne.

[Specially translated for THE MEDICAL PRESS AND CIRCULAR.]

Before entering upon this discussion we must come to a definite understanding whether the emancipation of cells, which is characteristic of malignancy, is due to a fundamental alteration in their biological properties, or whether, on the contrary, it is secondary to this original and accidental isolation, and is produced, so to speak, from a group of cells. In other words, do the cells escape control because they have become malignant, or do they become malignant on account of their accidental separation from the original tissue?

The majority of pathologists incline to the opinion that the characteristic features of malignancy are due to a change in the biological properties of the cells, and that the emancipation of these cells from their point of origin and their subsequent intrusion into the neighbouring tissues is a result of this change.

Theirsch was the first to attack this theory by stating that this emancipation was facilitated, in cutaneous cancer, at any rate, by a senile loss of resistance on the part of the subjacent tissues. Weigert still further defined the situation by noting that cellular proliferation is always due to diminished resistance on the part of the surrounding tissues.

Cohnheim rejected the hypothesis of the primitive alteration, and attributed the development of these malignant neoplasms to congenital isolation of a group of cells. Ribbert, however, maintains that the development of a malignant neoplasm is preceded by an inflammatory reaction in the adjacent tissues, that the separation of a group of cells from their site of origin is the result thereof, and that this isolation, considered by Cohnheim to be congenital, and by Ribbert to be acquired, is in reality the primary cause of malignant degeneration. All neoplasms can be explained by its mechanism. Ribbert's theory, that combines both Cohnheim's and Weigert's, is that he attributes the fundamental cause to cellular isolation, and the cause of the malignant proliferation to a lessening of the normal resistance of the adjacent tissues.

This hypothesis, however, does not explain the genesis of cancer. It alters our preconceived idea, in that he attributes the principal rôle to the connective tissue instead of to the epithelial cells. If, therefore, the isolation of the cells constitutes the chief etiological factor in malignant degeneration, it leads us to suppose that in these natural conditions the cells are endowed with destructive powers in respect of the surrounding tissues and the capacity for unlimited proliferation, and that these qualities remain latent until the cells accidentally become isolated, when they manifest themselves and transform inoffensive epithelial cells into cancer cells.

Experiments were made to prove this theory by Ribbert, Lubarsch, Lengemann, who attempted to produce a malignant growth in an animal either by implanting fragments of epithelial tissue in other organs, or by injecting epithelial cells into the blood stream, but the results were negative in every instance. Fütterer made a large number of injections of cells into the circulation of dogs, monkeys, rabbits, &c., and although the animals were kept under observation for a period of six months, none of them showed any proliferation of cells implanted or injected. Lack, however, succeeded in producing an epithelial tumour in a rabbit, which did not manifest itself until a year after the introduction of ovarian juice into the abdominal cavity. As this is the only positive instance, we are inclined to look upon it as a mere coincidence.

It will be seen that Ribbert's theory has not received any support, either from experimental or clinical observation, for cancer would certainly be much commoner than it is at present if its causation depended on the accidental displacement of a group of cells, either by inflammation or by operation. It would seem, moreover, that cutaneous cancer is ill-adapted for such researches, as there is great difficulty in distinguishing normal from neoplastic cells, and whereas changes in the cubical cells of the alimentary canal would be more readily noticed. Hauser directed his attention to polypi of the large intestine, in which carcinomatous degeneration is fairly frequent, and he arrived at the conclusion that there was a primary degeneration of the epithelial cells, which was the first manifestation of malignant transformation, and preceded the spreading of the disease.

This is in opposition to the result obtained by Ribbert.

We may safely admit, with these results before us, that there is unquestionably a primary alteration of the cells, which ultimately becomes neoplastic.

These interpretations carry us into the domain of philosophic speculation, a domain particularly rich in hypotheses, and these theories, which are essentially pathogenic and not etiological, do not throw any light on the real cause of malignant degeneration.

Several of them have one point in common, and most authorities agree with Cohnheim in recognising the analogy of malignant neoplastic cells to embryonic cells. According to Cohnheim, malignant tumours are due to a late development of these embryonic cells which have remained isolated, either as heterotopy or, at any rate, in respect of their organic relations. Von Haussmann considers neoplasms as embryonic in form, and adult, and differs from Cohnheim in holding that all the cells of the organism are capable of giving rise to tumours, and he therefore admits that the adult cells take on an embryonic form. Von Haussmann adopts this view, and explains it by an asymmetrical karyokinetic. He considers the movement of the cells to be retrograde, but Bencze thinks it is due to an ultra-differentiation of the cell—i.e., a cataphatic process, while Fabre-Demergue attributes it to a disturbance of the karyokinetic process, and Bastian to a
heterogeneous process by which the cells come to resemble protozoa, in the sense of becoming independent organisms. All these theories are, however, mere paraphrases of the main fact, namely, the primary alteration of the characters of the cell, and as to how this is caused we are still entirely in the dark. Hauser's theory does not enlighten us when he describes the necrotic cells as "foreign cellular race" resembling the normal organism both morphologically and biologically. Marchand simply calls it a "degeneration," which may be a congenital anomaly either local or general, due to a exciting cause, such as irritation, either mechanical or chemical, or simply to traumatism. Again, it may be an exogenous parasite, although this seems the least probable.

The structural resemblance of the malignant neoplasms to embryonic tissue depends more on their external anatomical characters than on their biological origin. We will now consider the question of growth of malignant tumours, especially of carcinoma, and try to ascertain whether the growth of these malignant neoplasms is due to a proliferation of the constituent elements of the growth, plus a progressive transformation of the infiltrated tissues, or simply a proliferation of the elements peculiar to the tumour. Let us take, for example, carcinoma of the skin. This, according to many, spreads by proliferation of the cells which have become cancerous and by a degeneration of the healthy epithelium at the periphery of the tumour. The cancer would thus spread by a multicentric process, as Petersen calls it. If this be the case we must confine our attention to the periphery of the tumours in studying the histogenesis of cancer.

The theory supported by Hauser and Fabre-Demergue is strongly opposed by Thiersch, Bard and Rübert, who assert that the growth of a cancer starts at a definite time in the double action and is due entirely to the proliferation of the cells which have become malignant, so that histological study of the edge of the tumour would afford no help. This categorical assertion is contradicted by the cases of multiple independent cancers, which are sometimes seen in the same organism, and of which we had an example in the case of a woman who had two independent cancerous growths, one of the scalp and another involving the temporal region of the opposite side, and who had been operated upon for cancer of the vulva several years previously. This tends to show that the same morbid process may repeat itself at different points in the same individual, and that it occurs especially at the periphery of the original tumour.

Petersen, by means of numerous sections, has shown that sometimes the cancer grows from one centre, and at other times from several centres, the spread in the latter case being due to a repetition of the cancerous degeneration of the epithelial cells at the periphery of the tumour. As to glandular cancer, Bormann and Petersen have demonstrated by sections that the increase in the size of the tumour in these cases depends on proliferation of the non-cancerous elements of the tumour itself, which is a point of view adopted by most pathologists of the present day. We have arrived at the same conclusion from sections of cancer of the stomach, so that we may confidently assert that the growth of the tumour is due to a multiplication of the elements of the tumour, though sometimes extension may take place from the development of fresh neoplastic centres at the periphery of the growth.

This question is not devoid of practical interest, for if the growth of the tumour takes place in this way, it is on the principle arguments against the parasitic theory of the growth of cancer.

The partisans of the parasitic origin of cancer in 1858 were divisible into three classes, according to the theories of the hypothetic parasite to which they attributed the etiology of malignant tumours.

Some incriminate bacteria, and others sporozoas. The sporozoic theory was introduced in 1890 after the discovery of the proto-coccidioides by Barran, &c., in Paget's disease. In 1893 Kahane attributed it to a fungus belonging to the group of blastomycetes. Sanfelice and Roncali arrived at analogous results a short time after, and with regard to the first group, Doyen discussed the idea of a kind of streptogonia, in malignant tumours, but not limited to these, since he succeeded in finding it in innocent growths. He called it the "Micrococcus neoforman,' but did not explain the etiological significance, nor has he vouchsafed any information since.

In the second or sporozoic group much has been written, and the most important contribution is that of Plummer, out of a total of 2,728 he found a parasite resembling a protozoa, and although the majority of his experiments on animals have given negative results, this has not been uniformly the case. In a series of inoculation experiments on guinea-pigs and into the cornea of the rabbit, he was able to produce an endothelial neoplasm containing the parasites in question. Experiments are still being made by the author to elucidate its etiological nature. Gaylord noticed these typical elements described by Plimmer in numerous cases of cancer of the breast, ovaries, uterine glands, stomach, gall-bladder, liver and kidneys. On the other hand, they were conspicuous by their absence in cases originating from the conjunctiva, epithelium of the skin and mucous membranes, and also in sarcomatous growths. In these latter he noticed a definite element, which he called the "pseudo-muscle" of which was identical with those fuchsisia-stained cells described by Russell.

Feinberg, in some researches carried on under van Leyden's direction, noticed the cells described by Petersen in cases of sarcoma, but he was unable to make cultivations of them. His proof of the parasitic nature depends on the existence of a double membrane, of a central corpuscle surrounded by a colourless zone, and a zone of protoplasm in contact with it. The parasites, which are stained by protoplasmic reagents, whilst the central nucleus is only affected by those reagents which stain cellular nuclei. Feinberg maintains that their characteristics are sufficient to distinguish these elements from all products of cellular degeneration and to prove their parasitic character. He also calls attention to the absence in these elements of chromosomes and of a chromatic reticulum, the absence of which is seen also in the cellular nuclei of the lower organisms. He calls the parasite the "Histoplasma canceromato- sum," and is prepared to explain the histological properties of cancer by studying the biology of sporozoic parasites. Slibing's parasite, the minifera and not to the coccidia. It resembles the elements just described, and in addition he has contributed much information as to their phases of development in animals. The parasites were found in all cancers examined, and succeeded in making a culture thereof, by means of which he was able artificially to produce carcinomatous tumours in mice. Further research by Israel and Lubarsch failed, however, to confirm the results obtained by him.

Two years ago Schiller discovered the parasite of carcinoma and sarcoma, which differed a good deal from the others, and could be distinguished by its brownish-yellow colour and marked refractility. At a certain phase of its development, it looked like a capsule containing a large number of granules, which he considered to be the true parasites. The granules were each capable of becoming a distinct capsule, a kind of sporocyst, and of multiplying by direct division. Schiller has not definitely settled the nature of the parasite, but he is inclined to look upon it as a protozoan, larger than a vegetable organism, and not its presence in the contents of the abdomen and intestine should be used as an aid to diagnosis.

Bra described a parasite of vegetable origin belonging to the group of the hypobacterial parasites, which he met with in carcinomatous and sarcomatous tumours, as well as in the blood of persons suffering from malignant disease. He was capable of producing in animals sometimes an attack, sometimes a cure. In other cases it gave rise to tumours which had the appearance of fibrosarcoma or carcinoma.
Leopold classes the parasite among the blastomycetes. Behla believes the parasite of cancer is the chytridiace, a fungus of very primitive structure, and allied to the myxomycetes. He explains the occurrence of cancer on the external body in the vegetable parasites. The prophylaxis consists in avoiding water from streams or reservoirs, and the consumption of fruit and raw vegetables. He recommends extreme cleanliness in all who have to labour on the soil.

From this enumeration it will be seen that there is a total want of unanimity among various authorities as to the parasite, but all these must have common elements are really Von Leyden's parasite, which he calls "pigeon's eyes," which have been called by some protozoa (sporozoa or foraminifera), and by others fungi (blastomycetes or ascomycetes).

Another theory recently put forward is that of Kelling, which differs absolutely from all the others. Kelling conceives that cancer cells may very well be the cells of the lower animals (insects, slugs, worms) which have accidentally gained admission into the bodies of a vertebrate, and have there multiplied. He describes a case in which he injected into a dog from a slug, which seven days later gave rise to an adenosarcoma.

In addition, this theory does not fit in with any of the facts of pathological anatomy.

Many objections have been urged against the parasitic origin of cancer. In cancer formed from squamous epithelium one meets with so many differently shaped cells in every lane which have gained admission into the bodies of a vertebrate, and have there multiplied. He describes a case in which he injected into a dog from a slug, which seven days later gave rise to an adenosarcoma.

In glandular cancer, on the other hand, we so constantly see the "pigeon's eyes" that their uniformity of structure in the different cases is difficult to explain by a mere process of degeneration. The elements known as "pigeon's eyes" look like round or oblong vesicles, with a well-defined edge, and contain a corpuscular body which is found in the protoplasm of the cell, and displace the nucleus towards the periphery of the cell. Several of these vesicles may be present in one cell, but it is rare to see a large number. Of these vesicles one may be found containing several central corpuscles. As to reaction of these elements in regard to the different stumps, it has been noticed that when this vesicle is stained with protoplasmic colouring reagents, the central body is always able to inculcate the reagent.

Both cancer of the breast and of the rectum show these elements. Most authorities consider these elements in loko to be parasites, whilst Sanzio, and Leips, guinea-pig under the microscope to be the parasite and the surrounding vacuole the result of degeneration caused thereby.

Vrchnow, in 1851, described some products of cellular degeneration which he called "physaliphore cell," evidently similar to what is now looked upon as a parasite.

Burrel, basing his observations on normal epithelial cells, explains the formation of these elements by a degeneration of the cenostomes, which are corpuscles situated close to the nucleus in the apocrine plasma. These cenostomes, by a process of degeneration, surround themselves by a vacuole, and the vacuole contains a corpuscle which constitutes the element known as "pigeon's eye."

Nösske, under Marchand's guidance, has shown that the so-called parasites of glandular cancer are composed of a coagulated substance, the concentration of which gives rise to the central corpuscle. This vacuolation takes place principally in the cells of glandular cancer, sometimes also, but rarely, in innocent tumours and inflammatory processes. The special stress of the shape of these so-called parasites, which, in his view, militates strongly against their parasitic origin.

Lubarsch inclines to the view that these "pigeon's eyes" are formed externally by the properties of leucocytes, or red corpuscles which have gained admission into the cell protoplasm, partly by the hypothesis of Burrel, and partly by that of Nösske.

As to Schullier's parasite, the brown capsules are described by Vöckler as being wood cells introduced into the specimens by means of reagents, corks, &c.; and according to Döf, zoology does not recognise any of the parasites described as belonging to the group of protozoa.

We have already mentioned that many authorities, the latest of whom is Wlafft, think they have been able to produce a malignant neoplasma by inoculation of a culture of saccharomyces obtained from a tumour, but Curtis and Sternberg and others have demonstrated that the tumours so formed consist of granulation tissue, consecutive to chronic inflammation.

Nichols, from numerous experiments with the blastomycetes of Sanfelice and Plümer, arrived at the conclusion that they are not identical with the cellular inclusions of cancer, and that they really have nothing to do with the origin of human cancer, and that the cancer obtained by Sjöbring in the mouse, according to Jürgens, is only the normal mammary gland structure of the animal.

Burrel has been looking for the pathogenic agent or its analogues among the micro-organisms which up to the present are invisible and pass through filters. With this object in view he has been studying a group of affections called by him "infectious epitheloses," which includes typhus-pox, vaccinia, small-pox, apthous fever, bovine plague, and molluscum. All these diseases, he points out, affect epithelial tissue and are due to a virus that passes through a filter, and from analogy he concludes that cancer has a similar origin. He recognises, however, that the cancer that gives rise to metastases in cow-pox derives from those of cancer. In the former, they are due to a proliferation of the already existing cells, while in the latter they are due to the deposit of cancerous cells in the lungs from the primary tumour.

This difference deters the author from attributing too great a similarity to the infectious epitheloses and the carcinoma les, for although the latter are found in the protoplasm of the cell, and displace the nucleus towards the periphery of the cell. Several of these vesicles may be present in one cell, but it is rare to see a large number. Of these vesicles one may be found containing several central corpuscles. As to reaction of these elements in regard to the different stumps, it has been noticed that when this vesicle is stained with protoplasmic colouring reagents, the central body is always able to inculcate the reagent.

Both cancer of the breast and of the rectum show these elements. Most authorities consider these elements in loko to be parasites, whilst Sanzio, and Leips, guinea-pig under the microscope to be the parasite and the surrounding vacuole the result of degeneration caused thereby.

These cenostomes, by a process of degeneration, surround themselves by a vacuole, and the vacuole contains a corpuscle which constitutes the element known as "pigeon's eye."
bile-ducts. Tyzzer, after much research, arrived at the conclusion that this also is an inflammatory and not a malignant process.

Case 1 asserts an analogy between malignant neoplasms and certain chronic affections. The site affected in both cases is the same, namely, those parts exposed to mechanical irritation, such as the lips, perianal region, and for cancer of the skin, and for carcinoma of the parts, such as the face and hands. Lubarsch shows that it is not so much the mechanical irritation as the physiological function that predisposes to the development of new growths. In support of this are the instances the frequency of cancer of the breast in women and its comparative rarity in men.

The real analogy between these infections and malignant neoplasms lies in their dissemination in the body by the lymphatic vessels and lymphatic glands, and the formation of metastases by their invasion of the vessels; but this similarity is not sufficient to enable us to assign to malignant tumors a parasitic origin.

Let us for a moment compare cancer to tuberculosis or actinomycosis. In the first place, we have to decide whether all tumors, innocent or malignant, are due to a parasitic cause. This cannot be intended, even by the most fervent supporters of the parasitic theory, because many of these innocent tumors, such as cutaneous fibroma, angiomata, lymphangioma, and enchondroma, and some lipomas, are congenital and occur as malformations.

The parasitic theory applies, therefore, only to malignant growths, but here the difficulty begins, because it is often far from easy to distinguish malignant from innocent tumors. The two distinguishing characters of malignancy, viz., unlimited destructive proliferation and the formation of secondary growths, do not always coexist, but form varying combinations. Sometimes we meet with a chondroma which has the characters of an innocent tumor, yet gives rise to secondary deposits, while, on the other hand, we meet with cases of carcinoma or sarcoma in which there is no metastasis. It is evident, therefore, that innocent tumors are closely allied to malignant growth by an uninterrupted chain of intermediate phases, and that a tumor that has presented all the signs of innocence for a considerable time may, as the result of traumaism, rapidly develop a malignant character. These transitions do not take place only in acquired benign tumors, but to an even greater extent in congenital benign tumors. This is seen, for example, in congenital tumors of the parotid gland, fibrous nodules in ovarian dermoid cysts.

The supporters of the parasitic theory date the development of malignancy from the moment the tumor or tissue is invaded by the hypothetical parasite. This explanation is plausible, in view of the fact that neoplasms due to a congenital inclusion present from the start the signs of malignancy, as, for instance, in congenital tumors of the kidney. In such a case it would be necessary to assume that the parasite was the cause of the heterotopy, or that it had found its way into the cell during intra-uterine life. Even if we accept the parasitic origin as proved, we must hesitate to state at what moment the parasite begins to play its rôle.

The growth of a malignant tumor by proliferation of its elements and not by infection of the surrounding tissues is scarcely consistent with the presence of a parasite. Not only should we have to admit the existence of special parasites for every kind of cell, but we should be constrained to admit that these parasites are in many cases incapable of transforming the healthy homologous cells of the surrounding tissue into neoplastic cells. Such a parasite would be widely different from any we have met with up to the present.

Feinberg tries to explain away this difficulty by assuming the existence of a kind of adaptability between the parasite and the cancer cell, so that the parasite has become incapable of penetrating into the epithelial cells of another organ, and he sees in the growth of cancer by proliferation of its elements a proof of the parasitic origin of the disease. This seems perfectly clear when we are dealing with epithelial cells of a different kind (metastasis of cancer in another epithelial organ), but it seems less applicable when it concerns the cells of the same organ. In my opinion the proliferation of the elements of cancer does not prove the parasitic origin of carcinoma.

Hauser, who admits the continuous repetition of the process of carcinogenization of the skin, degeneration at the periphery of the neoplasm, and the slow transformation of normal into cancerous cells, is less hostile to the parasitic theory than many pathologists.

Carcinoma, cancer caused by an epithelial parasite, sarcoma should be due to a parasite of the connective tissue or rather—for one must remember the many different varieties of sarcoma—by a multitude of different parasites, some of which has its predilection for one or other kind of connective tissue.

If we take for granted that the neoplastic cells spread the tumour, and that each cell transported into a suitable milieu is capable of producing a secondary growth, we find ourselves in a dilemma. 1. Either each neoplastic cell which is able to spread the tumour contains a parasite, or a parasite is found in each group of cells which has produced a secondary growth. This hypothesis seems very plausible. It reduces to naught all the discoveries of parasites that have been made, for protozoa and blastomyces are large enough to be seen under a microscope, and they are absent in many growths, and in the cases where they are present they exist in normal numbers. To prevent the hypothesis from falling through, we should be obliged to have recourse to the invisible parasites described (?) by Borrel.

2. Or, the presence of a parasite is not indispensable in all neoplastic products, the parasite being able to produce a growth only in the primary tissue of the cancerous cell (carcinoma) and the connective tissue in sarcoma, and proliferate indefinitely, thus conferring upon them the character of malignant cells differing from normal cells in the power of causing secondary growths apart from the parasite. This somewhat resembles Dor's theory, according to whom the transformation of the normal into the malignant cell is to be attributed to a cellular decadence brought about by an unknown parasite. In adopting this hypothesis we reduce materially the etiological importance of the parasite, for then the growths would be due to the local traumaism and mechanical irritation, so we should be brought back to the irritative theory, which is admitted by many of the adversaries of the parasitic theory.

These few observations suffice to show that the theory of the parasitic origin of cancer, instead of explaining away all difficulties, gives rise to so many new problems which are as difficult to solve as the development of a malignant tumor without the intervention of a parasitic agent.

The search must be continued, but by means of experiments from animal to animal, and not from man to man. This should be easy enough because cancer is common in dogs and mice. First of all one ought to find out whether cancer is transmissible by the cancerous juice, rigorously excluding in these experiments the transplantation of cancer cells. If one could thus discover the vehicle of the virus, it would make it less difficult to determine its nature.

SOME OBSERVATIONS UPON INFANTILE SPASTIC PARALYSIS AND ITS TREATMENT.

By ROBERT JONES, F.R.C.S.E.,
Hon. Surgeon, Royal Northern Hospital, Liverpool.

For the purposes of this paper I group cases into those of—(1) hemiplegia; (2) cerebral diplegia, and (3) spastic paraplegia. Of 850 cases I have been able to collect from various sources: 30 were hemiplegic; 142 monoparetic; 157 diplegic. This vast disproportion between the hemi-
plegic and the other groups is not borne out in my own experience, which favours the preponderance of the diplegic type.

Most generally the hemiplegia is an acquired, not a congenital, affection. It usually appears before the fourth year and is more common in the female. For several months there are no convulsions, and in quite a number of cases there are acute febrile symptoms which are an interesting contrast to the onset of adult hemiplegia.

If the arm is flexed and adducted, and the arm and limb are powerless. Deformities soon follow. The foot is arched and adducted; the knee is bent; the hip is internally rotated, somewhat adducted, and the femur is bent on the trunk. This arm is held above the elbow and when the wrist is dropped, the hand pronates and deviates towards the ulnar side, and the fingers generally grasp the thumb, which lies very forcibly adducted. As in the case of adults, rigidity of the affected muscles comes in on the generality of cases. This rigidity becomes more marked if the limb be moved either passively or by the child, and disappears under an anaesthetic. The onset is very often precipitated by a change in the character, and may accompany either right or left hemiplegia. Then follows an inequality of growth. This is more marked in the arm than in the leg, a fact which is sometimes lessened or annulled in the latter by the more frequent exercise of the leg. I have seen the affected arm three inches or more shortened: it is rare to find the leg over an inch shorter than its fellow.

Of chief interest to us from the point of view of treatment are the following facts:—
(a) The upper limb is more severely affected than the lower. (b) The lesion of the upper limb is more permanent. (c) The power of co-ordination of the hand with simultaneous extension of the fingers is lost. (d) That movements are performed without precision, spasmodically and slowly. (e) That the power of adduction of the thumb is lost.

The disabilities of the lower limb are generally—
(a) Contraction of the knee. (b) Extension of foot. (c) Internal rotation of the femur with adduction. (d) General rigidity.

The cerebral diplegic group is by far the most serious, as we have here to deal with both arms and feet. Unless the hands can be used the surgeon is sorely handicapped in any effort he may make to improve the condition. The question of the co-ordination of the limbs may divide the group into—(a) Cases with, and cases without, severe mental complication. (b) Complete and partial disability of hands. (c) Complete or partial disability of limbs. (d) Cases complicated by athetotic movements.

In a number of cases the spasm is confined to the limbs, and this is the group to which we give the name of Little's disease or spastic paraplegia. Of the vast majority of cases even in this last group a varying degree of mental derangement will be noted, and in many athetotic movements are present. A typical case of spastic paraplegia brought to the surgeon at the age, say, of twelve months is characteristic: usually no contractions have occurred at the hip or knee; the child's legs are rigid; the toes are pointed; there is usually no internal rotation, and adduction is not sufficiently severe to cause a crossing of the limbs. The reflexes are exaggerated, the patellar reflex not usually causing a knee-jerk, but a leg-jerk. If the little patient be held by its arms there is no endeavour to separate the limbs, and should the toes be brought to the ground, and an effort made by the child to walk, both limbs act synchronously and in parallel lines. When passive separation of the limbs is made, although it is found that one can see the spasmodic efforts of the powerful adductors. If at a later stage the patient is able to walk, several changes will be noted. The addiction will be more marked; the scissors walk will have developed, and a characteristic dragging of the left or right leg will have occurred, which becomes more pronounced when any attempt at running is made. The body pressure is mainly transmitted to the ball of the toe. These contractures, however, at this stage are generally spasmotic, and there is no appreciable shortening in length. The shortening occurs at a still later stage, and is known as contracture.

In quite a number of cases the patients are in a hopeless position as far as the limbs are concerned, as they make to move only serves to throw the muscles into violent contractions, and the legs into extreme adduction. The most severe type of contractions in the lower limb is that of the infantile type, with slight mental defects, and unaccompanied by hemiplegia.

Before discussing treatment, I will briefly touch upon the pathology of spasmodic paralysis, if only to suggest how futile are operative procedures directed at the primary lesion. The pathology of hemiplegia, hemiplegia, paraplegia, and diplegia are the same in kind. The symptoms are due to the retardation of growth, resulting generally from embolism or thrombosis, together with changes in the spinal cord. In later cases one finds wasting and sclerosis of the motor tracts, with often a loss of substance in the form of cavities or cysts known as porencephalus. These cysts occur on the surface of the brain and sometimes dip fairly deeply into it. They seem to be a late result in a growing brain, and to have produced an extensive scar substitute for cerebral tissue. Should the porencephalic cavity be in the hemiplegia, it is likely to result in hemiplegia. If the scar is bilateral, diplegia or spastic paralysis results. The lesions, therefore, are a late product of a hemorrhage, an embolism or a localized encephalitis.

The treatment of spastic paralysis has been too long in the hands of the physiotherapist. Much work has been done. Indeed, from medicine in this affection we have nothing to expect, apart from very indirect results, and we have only to scan the text-books and monographs to realize the futility of our efforts. I believe, however, that a large proportion of children suffering from severe spastic paralysis may be transformed into useful members of the community, improved both in body and mind, by the efforts, enabled to work with comparatively little deformity, generally only requiring the aid to be derived from one or two sticks.

The class of cases which we can place outside remedial art is the idiot, the microcephalic, and that violent irritative type of diplegic so often seen, subject to fits and active athetotic movements, who has generally lost all control over his secretions. The treatment of any condition short of this is a matter of varying success, subject to conditions which obtain in any surgical case requiring prolonged attention. For instance, active treatment may be required for two years. It would, therefore, be unjust to admit a case into hospital for two months, and then send it to a miserable home where neglect would be the inevitable sequence. Such a case, however, after hospital treatment, secure in the care of anxious, intelligent parents, no matter how poor, would prove a credit to all concerned. These are important matters which the surgeon must consider before he undertakes his work. Another class which gives the greater anxiety and trouble is that where the affection of the hands is of such a kind as to promise but slight hope of their assistance to the limbs during walking. Before despairing, however, I think it is well to give such hands the opportunity of a careful trial, both as a useful discipline and because success sometimes exceeds expectation.

I would divide the treatment of all cases of spastic paralysis into operative and post-operative. For although mechanism is involved in nearly every case there is only an insignificant minority which we are called upon to treat without invoking operative aid.

In infantile hemiplegia, if the paralyzing affection affects the arm much more than it does the leg. This is almost invariably the case, and in this particular it differs from diplegia, where, when the four limbs are attacked, the hands are less severely affected than the limbs. Indeed, in hemiplegia there is a paralyzing affection in a leg which is absolute, and in addition we have a complication in the shape of rigidity. The behaviour of the lower limb differs also from that of the spastic paraplegia, in
that the adductor spasm is proportionately not so marked.

The treatment of the hand and arm in infantile hemiplegia is distinctly less promising than in the diplegic case, but there are clinical signs to which I would draw your attention which help us to prognosticate success or failure. If the paralysis is complete, or, in other words, if the little patient is never known to relax his spasm, treatment is futile. If he only moves the fingers of his affected hand in conjunction with the fingers of the opposite side, the results will in all probability be discouraging. In all cases where the parents are able to say in the spirit of true observation that the patient is able to do more with one hand now than a little while ago, the success of treatment is assured. Similarly, where any degree of voluntary relaxation of spasm exists apart from an associated movement on the opposite side, treatment is emphatically indicated.

Noting that the dominant deformity in both hand and elbow is pronation and carpal flexion, treatment should consist in fixing the elbow supine and hyper-extending the wrist until the extension of the wrist should be combined with that of the fingers, and a special arrangement adapted to keep the thumb at right angles to the palm. The spasm in these cases is often pronounced that the extension of the fingers and thumb must be brought about very gradually.

If elbow movement is accompanied by contracture of biceps and brachial muscles, the supination may be combined with extension. If this is not the case the flexion position of the elbow will suffice. Instead of being firmly pronated the elbow lies semi-pronated, it is not necessary to treat it, and all one's energies should be directed to the hands.

It is difficult to give a reason as to how improvement comes about, but it may be taken as an axiom that prolonged fixation of spastic muscles in a position opposed to their contraction lessens the severity of the spasm. This is true where severe spasm is present and its influence may be tested even in spasmotic torticollis, intractable as we know that affection to be. It would appear as if the group of muscles at last got tired of trying to pull. If the case be mild, this treatment may be discarded in about twelve months, if during the whole of the period the extension of the hand has been kept up without intermission. The test for relaxation must be the power of voluntary movement, however slight it may be. It will be noted that generally at this stage the patient, in endeavouring to extend his wrist, will first of all close his fingers and will only open them on completion of extension. The process is reversed when the wrist is flexed.

In order to meet this difficulty the splint employed to extend both wrist and fingers is modified so as to extend the wrist alone and allow freedom to the fingers. At this stage or earlier the surgeon may decide whether in a given case such a modification may be predicted, and if he is in doubt, operation should unhesitatingly be performed. Operation will consist of tenotomy or tendon transplantation; myotomy need only be mentioned to be avoided. An incision is made over the tendon of the flexor carpi ulnaris just above the annular ligament, another is made over the flexor carpi radialis, and both tendons are divided low down and taken into the extensor extensor ulnaris, and (b) the radial flexor into the radial extensor. I performed the operation some time ago upon two spastic children, and in both instances voluntary movements were steadily performed, and, one, a girl of seven, was able to write quite a respectable hand. At the present time one of the worst cases of athetosis in connection with cerebral diplegia is an inmate of the Liverpool County Hospital for the Treatment of Children. When this patient entered the hospital nearly two years ago both limbs were firmly adducted, contracture had occurred which had so affected the feet that plantar flexion had occurred with almost equal elevation of each calcaneus and cuboid.

The skin of each dorsum being reddened by pressure from within. The hands were firmly flexed, and but little voluntary movement existed. Athetotic movements more resembling chorea with occasional jerks which almost lifted the patient from his bed complicated the treatment. So far as the hands were concerned, hyper-extension such as I have described was practised, and, later, division of the flexors of the wrist. The little patient has steadily progressed. He can voluntarily move the fingers of his affected hand in conjunction with the fingers of the opposite side, the results will in all probability be discouraging. In all cases where the parents are able to say in the spirit of true observation that the patient is able to do more with one hand now than a little while ago, the success of treatment is assured. Similarly, where any degree of voluntary relaxation of spasm exists apart from an associated movement on the opposite side, treatment is emphatically indicated.

Tenotomy alone has proved somewhat disappointing although one has had occasional success. The operation should be confined to the division of the flexor carpi radialis and ulnaris. It is, in my opinion, better to elongate the other flexors of the hand by a long median incision such as one would employ in lengthening the tendon Achilles. Tendon transplantation, however, is a better operation, less complicated and more trustworthy. The surgeon's art, however, does not end with the operation, and hyper-extension of the wrist, leaving the fingers and thumb in a semi-pronated position for a further few weeks.

In order to prevent adhesions after the operation, the wrist should be free but very gently, with, moved in a fortnight's time. Whether an operation be done or not, the final stages of treatment are identical.

There should consist in getting both guardian and patient to strive every nerve to urge and practise movements and to resist all temptations to take short cuts. Wherever confidence and instil enthusiasm. This cannot be done by a log face which crushes hope, nor by didactic references to a still more doleful pathology.

when he tries to walk is the narrowing of the pedestal upon which is the trunk rests, by reason of adducted limbs. One overcomes this, and that with the adducted limbs the body is poised upon a pedestal that is widened. During early training the nurse must see that while walking the limbs are not approxi-
        mately, and that from the first, swinging of the feet must be prohibited. Crutches should not be allowed until the patient has been taught to stand unsupported.

I need not enter into any more detail regarding this most important stage of treatment, but would add that much depends upon the intelligence and industry of the nurse very much.

Diplegic hands are treated on the same principles as I have enunciated in regard to infantile Paralytic hands and they must be taught to hold sticks and crutches with a firm unyielding grip. I cannot now deal with individual cases, but I may say I have operated upon cases from twelve months to twenty years of age. A large number of these were so bad that they had never attempted to place one foot before the other. Some were structurally fixed (contractured) at ankle, knee and hip. A most helpless youth of twenty, one could not in six months make him erect and walk with sticks, and twelve months later he would move his limbs north, south, east and west with hardly an appreciable jerk. Success in an infantile Paralytic case has to be measured by the place where the mechanical stage offers such difficulty, proves the accuracy and efficacy of the principles I have endeavoured to expound. It is logical to infer that old neglected cases are unamenable to surgical education that our prognosis should be very hopeful in the young.

With regard to the degree of benefit to be derived from treatment, the parents should be given to understand that under favourable conditions of nursing and tuition the child, aided by the hand or by sticks, will be able to walk distances in from twelve months to two years, and with that perfectly straight limbs and heels on terra firma. A large proportion of cases will later on manage aided by one stick. Even in the least successful cases, parents, mostly having despaired, are full of gratitude. The mental condition of the children obviously improves when their physical defects are remedied, and they are enabled to mix with their little friends. Complete recovery in spastic para-

plegia is, of course, impossible.

It will be gathered from my remarks that the treatment of spastic paralysis should resolve itself into a system. That system involves operative, mechanical and educational stages. The treatment cannot be separated into parts. If the surgeon is not satisfied that the case is to be under his control for several months he will consult his reputation best by leaving it alone. Operations not followed up by careful and prolonged after care give rise to disappointment and discred. Merely dividing tendons to be followed by massage and electricity is futile and dispiriting.

At the New County Hospital for Children at Heswall, we hope to have a ward for these spastic cases where we can keep them as long as needed. The nurses will be specially trained, and no opportunities will be lost from ignorance or neglect. The three months' time limit which general hospitals impose materially blights the prospects of paralytic subjects. They are neglected at home and wander from one institution to another, often the victims of conflicting theory and diverse practice. The successful hospital manage-

ment of infantile paralysis is not complete without an organised system of education being inaugurated. This in the case of spastics, must often be of the visual as opposed to the abstract type. Apart from its direct influence in improving the mind we find it to have a sedative influence on the irritable. I have often thought that if there were social institutions for the paralytic children of the well-to-do an undesirable gap would be filled. With cheerful surroundings these little ones would enjoy in happy combination a development of mind and body under the guiding auspices of specially trained instructors. Such ad-

By Howard G. Peeler, M.D.Edin.,
Late Junior Resident Medical Officer, Mount Vernon Hospital for Consumption, Hampstead.

Much has been written on this subject by authorities of eminence, and it is curious how widely their opinions differ. Some find the hemoglobin reduced, and others a surprisingly high rate of hemoglobin; Cabot and Bang held that leukocytosis is the result of complications such as severe hemoptysis, septic cavities or a pneumatic condition. The former notes that many immature red cells are thrown into the circulation as in chlorosis, but in fewer numbers.

Neusser and Holmes regard basophilia as of good prognostic importance. Megalocytes have frequently been noted in small numbers.

Undoubtedly the condition of the blood is largely a question of the stage the disease is at when the examination is made. Variations in clinically similar cases are wide—so wide, indeed, that statements must leave considerable margin.

The following is a summary of the examination of the blood in seventy-five cases of phthisis pulmonalis. In all the leucocytes were counted, and in the majority a count was made of leucocytes (quantitative and differential), hemoglobin and red corpuscles. Repeated subsequent examination was made in many cases. In arranging the cases examined it was found convenient to classify them according to the stage or complication of each. With very few exceptions the cases were being treated by "open-air" methods, with abundant nitrogenous feeding. The hospital where the observations were made is situated over 300 feet above the sea level. Even in the cases of those patients who were unable to undergo the full rigour of the treatment the "open air" factor was not absent, as they were treated in wards considerably more airy than those of general hospitals in which, we may conclude, all but the more recent published observations have been made. As regards drugs, such remedies as guaiacol, creosotal, &c., were used when the expectoration was very copious and purulent.

It has long been recognised that in many cases of phthisis the opportunities for septic infection are numerous. Thus in the bacteriological examination of fifty phthisical sputa, in addition to tubercle bacilli thirty-five showed cocci, and all except one of these cases had one or more of the following complications—cavities, phthisis laryngia, or pneumonia. Fifteen showed no cocci; of these seven had none of the above complications. It is not claimed that in every case the organisms found came from the bronchi or even larynx, but it shows that the opportunities of mixed infection are plentiful. In all tubercle bacilli were found, which argues in favour of the source being pulmonary. In all the cases but one of phthisis pulmonalis complicated by phthisis laryngia the leucocytes were increased in number, and more markedly so where ulceration of the larynx had taken place or where the laryngeal ulceration had had no local treatment at all. In the cases where the leucocytosis was smaller the laryngeal lesions comprised no ulceration, and one may infer that the breeding ground for septic organisms was less suitable than where ulceration had taken place.

Average of leucocytes in the non-ulcerative cases—16,180.

In the ulcerated cases—22,862.

One would expect to find the polymorphonuclear leucocytes increased in cases of septic infection, and so we find in the non-ulcerative cases 49.6 per cent. of these, and in the ulcerative 64.5 per cent. Two cases in this series were subjected to subsequent blood examination, and both showed improvement, one showed a further increase and the other a decrease in leucocytosis. This point will be referred to later. Of cases complicated by chronic bronchial catarrh no special mention need be made. In the group of "early afibrile" cases fourteen in number, there was a large increase of leucocytes in only four cases, and we expect to find much mixed infection in such cases.

In the "early febrile" series two cases show a temperature of over 102°F, and in these the leucocytic reaction was marked and the percentages of polymorphonuclear white corpuscles was higher than in others of the series, suggesting a septic infection. Comparing this series with the "early afibrile" class it is interesting to observe that in one would expect, the average leucocytosis in the febrile class is higher than in the afibrile. Thus—febrile cases, 19,326; afibrile cases, 15,321.

"Advanced afibrile" cases—Here there was a first no high leucocytosis, which is rather surprising, as with the large area of tuberculous and septic involvement one would expect a considerable reaction. The explanation probably lies in the supposition that the tissues have become accustomed to the presence of septic organisms, and have ceased to react.

In the "advanced febrile" cases also the increase in leucocytes is surprisingly low—no doubt for the same reasons.

"More advanced cases with cavitation is many" were classified together—a large class which comes between the "early" and "advanced" cases. This series does not call for special mention here.

For the sake of comparison with the blood of normal individuals it must be mentioned that the average number of white corpuscles per cubic millimetre in four normal cases examined by the same method and living under the same conditions was 10,158. Special note was taken of the amount and type of the expectoration in each case, but little assistance was gained by this, as the variations in apparently similar cases were great.

General Conclusions.

1. In the majority of cases of phthisis pulmonalis of all stages the hemoglobin is surprisingly high. Of those examined 88.2 per cent. had 70 per cent. or more of hemoglobin. In a few cases of both early and advanced disease it was found to be lowered. The proportion with under 70 per cent. of hemoglobin in this collection of cases was 14.3 per cent. If the rate is low at first it will increase as the patient improves under treatment.
The anaemia of consumptives is frequently more apparent than real.

2. The red corpuscles are generally present in normal or nearly normal amount and sometimes in abnormally high amount. Thus the cases in this series with red corpuscles numbering 5,000,000 or more make 61.5 per cent., while those with red cells less than 2,000,000, therefore included in the barely normal group, make up 38.5 per cent. of the whole. It is to be noticed that, as Cabot has pointed out, these numbers are attained by the production of many immature and ill-formed corpuscles. In the cases where the red corpuscles are found to be low at first, as the patient improves the number of red cells gradually rises. Definite poikilocytotic forms were not found.

3. In the anemias of phthisis a variable increase in leucocytes is present at some stage of their history. This leucocytosis is apparently of two kinds. (a) A polymorphonuclear increase where the entrance of septic organisms has called forth resistance by the leucocytes; (b) a basophile increase accompanying improvement under treatment with plentiful nitrogenous diet and hygienic surroundings.

Both forms are desirable. The first, because it shows that the system is resisting the mixed infection. The second, because it indicates that the blood and the body generally are responding to treatment. The first form is usually the higher in the severity of the case, and further, that these two forms of leucocytosis may coexist, or one be a variation of the other. That the basophile follow the polymorphonuclear form. It was noticed that in certain cases the polymorphs decreased in favour of the basophiles. Here, probably, the above-mentioned change from one form of leucocytosis to the other was taking place.

4. Some authorities have found that on improvement the leucocytes increased and others again found that they diminished. That both phenomena occur, and that there is a special significance in each, the writer believes. On looking into each group of cases we find that when the leucocytes increased after a period of treatment the initial count was higher. On the other hand, in the cases where the leucocytes diminished the first count was fairly high in every case.

This suggests that the leucocytes increase when their aid is needed, and diminish gradually when their protective work is done. No doubt the change from a polymorph increase, which is fairly high, to a basophile, which is lower, will account in part for the fall in some cases.

Of the cases examined immediately on admission 30.8 per cent. showed increase in basophile cells. Of those examined after varying periods of treatment 40 per cent. showed some degree of basophilia. Some cases also showed a degree of basophile increase not sufficiently marked to be classified with this 40 per cent. In this category must be placed cases with large initial polymorph increase which diminished as the patients improved.

Of the cases showing a basophile reaction after treatment and under sufficiently long observation for a conclusion to be drawn 81.2 per cent. made good progress and 18.8 per cent. were doubtfully improved. One is therefore inclined to regard the basophile reaction as a useful indicator of progress.

5. In a small number of the cases examined (9.4 per cent.) myelocytes were found in considerable numbers.

6. In certain cases the coarsely granular eosinophiles were noticed to increase with improvement.

7. It must be remembered that concentration of the blood from an exhausting disease must in many cases make the number of corpuscles and haemoglobin appear falsely high.

The variations in each class of cases are so wide that only general conclusions can be drawn. The trend of some recent writers has been towards attaching importance to the increase of basophile cells in considering prognosis. This leads one to recall the theories of those who regarded the gouty state—where basophile cells are plentiful, as inimical to phthisis. There is little doubt that the basophilia of consumptives under treatment is the result of heavy nitrogenous feeding. This is no doubt the cause in gouty conditions too. It is possible, therefore, that the connection between uric acid diathesis and a resistance to tuberculosis is that of a common cause.

Therapeutic Notes.

By GEORGE FOY, M.D., F.R.C.S., Surgeon to the Wilthorpe Hospital, Drumcondra, Dublin.

ANÆSTHOL.

This new anaesthetic agent is a chemical combination of 17 per cent. of ethyl chloride, 53.89 per cent. of chloroform, and 39.1 per cent. of ether. It is a clear, transparent fluid of a specific gravity of 1.045, agreeable in odour, and with a boiling point of 104°F. Meyer, who introduced the drug, and has used it extensively, recommends that it be administered by an Esmarch mask, which is covered with a doubly folded piece of sterilised gauze and a piece of oiled silk, the latter being an opening of the size of half an inch in the centre. The drug should be given as chloroform, drop by drop. Its administration is, if given slowly, unattended with struggling. As the patient awakens very quickly from its influence it must be continued throughout the narcosis; because of the low boiling point very little of the anaesthetic is stored in the body, the patient exhaling almost as much with each expiration as has been previously been inspired. In this consists its safety: the patient quickly recovers from its effects, indeed, he has never been deeply narcotised, for his reflexes have not been abolished. But such an anaesthetic can never be used for other than minor operations, without drawing, opening secesses and so forth. It will probably displace nitrous oxide gas and ethyl chloride, but it cannot replace chloroform or ether; nevertheless, its introduction is a decided gain to surgery.

CREOSOFORM.

The above is the name under which a combination of creosote and formic aldehyde is introduced into the market. It contains 96 per cent. of creosote. It occurs as a yellowish green powder, without taste or smell, and is insoluble in water and glycerine, but soluble in alcohol and alkaline solutions. Two to four grammes a day may be taken without any unpleasant effects resulting. It is said to possess all the physiological and therapeutic effects of creosote without any of its caustic properties, and that when prescribed with powdered sugar and a flavouring oleo-saccharate children take it readily.

THE INFLUENCE OF THE DIPHTHERITIC AND TETANIC TOXINS ON THE BLOOD.

In a paper read at the recent International Medical Congress at Madrid, by Dr. Henry
Kucharzewski, of Warsaw, the author, after describing in some detail the many experiments made on rabbits and other vertebrates, announced that he had arrived at the following conclusions:

1. Diphtheritic toxin when subcutaneously injected in large or full doses lessens the number of the red blood corpuscles and the amount of hemoglobin. In large doses the specific gravity of the blood is diminished. In lethal doses the toxemia always produces progressive hyperleucocytosis, which continues until death. When small doses are administered, if the animal survives, the curve of the hyperleucocytosis falls. During the period of hyperleucocytosis there is a marked augmentation of polymonuclear cells (pseudo- eosinophiles), which appear quickly after the injection and increase up to the death of the animal. The number of lymph-cells markedly diminish and the eosinophiles gradually become less and less until they finally disappear. In cases which do not end fatally the eosinophiles increase as the animal recovers. If the toxin is heated to a temperature of 158° F. and injected subcutaneously, no effect, toxic or otherwise, is produced on the blood.

2. Tetanic toxin when subcutaneously injected produces a fall in the number of the red blood corpuscles and in the amount of hemoglobin proportionate to the dose of toxin used. Large doses lessen the specific gravity of the blood. Intoxication by large doses produced marked hyperleucocytosis; after small doses this effect is not noticed. In the first moments after injection a condition of hypoleucocytosis is found. After the injection of a large dose this hypoleucocytosis is converted into a condition of hyperleucocytosis, although after a small dose the number of the leucocytes do not sensibly, augment and soon attain their normal amount. Polymonuclear cells increase markedly, but lymph cells sensibly diminish in number after a large dose. The number of eosinophiles also decrease under the intoxication produced by a full dose. Toxin which has been treated to a temperature of 158° F. produces no effect on the blood. The examination has shown to have a distinct use value as an aid to diagnosis and prognosis. We find a rapid increase in the number of the neutrophiles at the beginning of the intoxication, a diminution or even a disappearance of the eosinophiles in mortal cases, and an equally marked increase in their numbers in benign cases.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Clinical Evening.

MEETING HELD FRIDAY, OCTOBER 23RD, 1903.

DR. FREDERICK FRIDAY, President, in the Chair.

A CASE OF DERCUM'S DISEASE (ADIPOSIS DOLOROSA) IN A MAN.

DR. LEONARD WILLIAMS showed the patient, who up to two years ago had always enjoyed good health. At that time, owing to lack of employment, he became a harman at a beer and wine shop. His present troubles began soon after this change of work, and has developed gradually since. There were bilateral, more or less symmetrical swellings distributed over the trunk and upper arms, the face, forearms, legs, hands, and feet being free. Some of these swellings are typical lipomata, others give the sensation of a varicocele, while the larger ones suggest the feeling of a mamma.

Their development was accompanied by pain, which gradually subsided as they got larger. Pain is, however, very easily elicited by rough handling, and paroxysms of pain occur, not infrequently without any cause. There is a general tendency to hemorrhages over these swellings, occasionally after any exercise of the underlying muscles. The patient has become progressively asthenic since he came under observation two months ago. There is only one other recorded case of this disease in a male. A. B., of Florida, was one of a double lipoma, and he pointed out that in these cases there was frequently a history of alcohol. This seemed to apply in the case before him. He commented on the occurrence of pain usually present in cases of Dercum's disease.

Dr. French inquired as to the mental condition of the patient.

Dr. Hill, in reply, said there was also a history of alcohol in the recorded cases of Dercum’s disease. He explained that pain was a prominent symptom in the present case before the tumours appeared. In cases of Dercum's disease there was a general tendency to hemorrhage as in this case. The general muscular power was below par.

A CASE OF ECTOPIA VESICE AFTER OPERATION.

Mr. Thos. H. Kellock showed a boy, now 2d., who was the subject of our case. There is nothing noteworthy in the family history, he has enjoyed fairly good health. The operation performed in two parts. On the first occasion, June 1903, the penis, which was, as usual, in a constricted stage, entire episadias, was dissected from the scrotum, behind what represented the symphysis pubis, and fixed in that position by sutures. At a second operation in August, the visible portion of the bladder was dissected up, turned down, and drawn under the arch of skin in front of the symphysis by sutures passed through its margins, left long, and attached to the skin of the thigh. A few sutures were passed through the bed of the bladder thus turned down to fix it to the back of the bridge of skin. It was intended to graft the raw surface left where the bladder had been; but this healed over so rapidly that it was not required. A small leak occurred at the side of the inverted bladder which was healed by a slight plastic operation, and it has now practically closed. All the urine now pass along the penis into the periurethral wound, and it is in that way it will be possible to collect it in an apparatus without much inconvenience to the patient.

A CASE OF TUMOUR AT THE BASE OF THE SKULL.

Mr. Kellock also showed a young woman, 2d, history of syphilis. When three months old the mother noticed that the right eye was getting larger and the side of the head projecting, and this condition has increased slowly to the present time, with apparently causing any pain or inconvenience. Shortly before admission the child had a fall and was unconscious for some time. He is quite intelligent, shows some signs of rickets, the anterior fontanelle is not quite close. The right eye is prominent, and the globe seems to be enlarged and a little lower than the left. There is considerable bulging in the right temporal region, the swelling is bony; the head measures twenty-one inches in circumference, and there is a little bulging in the corresponding position on the left side. The upper jaw is apparently a little further forwards on this side, and the interval between the central incisors is to the left of that in the lower jaw. There is a difference when the ears on the two sides, that on the left being more pendulous. On examining the back of the pharynx there is a distinct prominence—apparently the normal position of the tongue. The uvula lies on the right side. There are no paralytic symptoms in the face or rest of the body; the kne-jerks are normal. Scattered over the front and back of the trunk are numerous oval-shaped spots of light brown colour; these have been present since birth. Examination of the abdomen reveals nothing abnormal in the region of the left kidney; the right is covered by the liver, which is
pushed downwards by the shape of the chest. Report on the condition of the eyes by Mr. Lister—"Right globe in slight displacement downwards, slight ptosis. Movements of globe free in all directions. Right cornea distinctly larger than left. Tension +. Pupil dilated, inactive to light. Anterior chamber deep. Media normal. Fundus well marked—copping of disc. Left fundus, no copping of disc, no sign of neuritis."

CASE OF VASCULAR NASO-PHARYNGEAL FIBROMA OF EXTENSIVE ORIGIN—OPERATION.

Dr. BERTIL TILLEY showed a lad, aged 14, who complained in November, of complete nasal obstruction associated with blood-stained discharge from left nostril of five months’ duration. Examination showed a large, sloughy, easily-bleeding mass completely filling left nasal fossa from anterior to the posterior nares. First operation (November 20th).—Ollier’s method. Only half the growth could be got away; very free haemorrhage. Second operation (December 7th).—Preliminary laryngotomy; division of soft and removal of left side of hard palate. An extensive growth thoroughly removed. March 15th, 1902.—Extensive recurrence. Similar operation to No. 2. July 31st, 1902.—Extensive recurrence. Preliminary laryngotomy. Soft parts of face and investing tissues removed up to base of skull; large opening made in left canine fossa; ascending process (lower half) of superior maxillary removed. Growth seen to arise from external surface of frontal and ethmoidal region. Complete removal. Since that operation there has been no recurrence, patient has grown four inches, and early this year the soft palate has been sutured.

TWO CASES OF OSTREITIS DEFORMANS.

Dr. HERBERT FRENCH showed a man, aged 54, a painter. There was marked thickening of both tibia and fibula, with increase of curvature. Thickening of right patella, right femur, right clavicle. Kyphosis in dorsal region, lordosis in lumbar. No affection of cranium. Right leg half an inch shorter than left. Walks bow-legged, and is obliged to use a stick. The condition began three years ago, and has slowly progressed. He first noticed it after an acute attack of gout. He also showed a woman, aged 53, a widow. Both tibiae were thickened and bowed forwards, especially the left. Right femur swollen and bent with convexity outwards, the maximum bend being five inches above the patella. Kyphosis in dorsal region, lordosis in lumbar. Right leg one inch shorter than left; walks with a limp, but can do so without a stick. The condition began ten years ago, and has been slowly progressive. She first noticed it three years ago, and was menopausal.

Mr. BOWLEY remarked that Sir James Paget had described cases affecting one bone only, doubts having been expressed as to whether these should be included in osteitis deformans. He thought that one of the author’s cases which started as disease of the femur only formed an important connecting link between the two groups of cases.

Mr. BARNARD related similar cases and inquired as to the frequency of spontaneous fracture. Dr. FRENCH mentioned a case which started in one-half of the skull only, and referred to cases of spontaneous fracture in osteitis deformans which united without any trifling splint. He pointed out that the disease was unknown in Germany, where, on the other hand, osteo-malacia was fairly common.

A CREOSOTE INHALER REMOVED FROM THE OESOPHAGUS BY GASTROTOMY, WITH SKIAGRAM SHOWING THE INHALER IN SITU.

Mr. HERBERT J. PATTERSON showed a specimen, interesting as showing the feats which can be performed in the way of swallowing by persons other than professional sword-swallowers. This cylindrical metal case, measuring four and a half inches long, and almost two inches in diameter, was accidentally by a gentleman suffering from phthisis. Inside the metal case was a glass inhaler containing a draught of creosote. The accompanying skiagram showed the metal case lying to the left of the spine, and with its long axis almost parallel to the vertebral column. Its presence could not be detected by abdominal palpation even under the anaesthetic. He opened the stomach and removed the case. It was impacted in the oesophagus, with about one inch of its lower end projecting into the cardiac end of the stomach. The patient made an uninterrupted recovery.

CASE OF A CHILD WITH APPARENTLY COMPLETE ABSENCE FOR SEXUAL ORGANS.

Mr. EDGAR BEAUMONT showed a lad born August 10th, 1901, whose complete absence of seminal organs was demonstrated by the absence of the abnormal formation that lends the chief interest to the case, was quite normal. The child is very intelligent—and, exceptionally so, and of prepossessing appearance. The parents are both healthy, and there has never been any other trace of sterility or deformity in the family. The child has cut eight teeth normally. The only special feature noticed in the child, since its birth, is that at times when the urine dribbles away for a few moments and then passes freely, it perhaps reverts again to the dribbling; but this is only occasional, and at other times the urine is passed freely and without effort.

Mr. KELLOCK pointed out the importance in these cases of the question of sex, and remarked on its greater frequency in males.

A CASE OF SARCOMA OF THE LEFT SUPRARENAL GLAND WITH SECONDARY DEPOSITS IN THE CRANIAL BONES.

Mr. HAROLD L. BARNARD showed a male child, aged 23, who fell upon his head six weeks ago. His cheeks and eyes began to swell next day. A week later he became listless, peevish, without appetite, and he vomited twice the same week. Since his admission to the hospital three weeks ago the swelling has increased with great rapidity. The entire head is now enlarged, and the cloudy eyes are in the stage before the sockets. Soft masses project from the forehead; the temples and the cheeks are smooth and white with pressure. The blood-count shows that there is moderate anaemia. The leucocytes are not increased above 8,000, and the differential count reveals only a slight increase of lymphocytes. In the left hypochondrium is a tumour which is probably a suprarenal one. It lies deeply and is irregular. There is gut in front of it; but it has no sharp edge or notch. The tumour which was obtained from an almost identical case, shows a soft haemorrhagic sarcoma separating the pericranium and dura from the membrane bones of the skull. The suprarenal was the only other growth in the body.

Mr. BOWLEY expressed the thought that the cases might serve as the basis of a further communication.

Mr. BARNARD compared the condition with that of chloroma, which always affected other bones than the skull bones, especially the sternum and vertebrae, whereas these cases were limited to bones developed in membrane.

A PEDICLE TRIDENT FOR MULTIPLE LIGATION OF PEDICLES AND OMENTUM.

Mr. HAROLD L. BARNARD showed an instrument devised to avoid the danger and difficulty of in multiple ligature of pedicles and omentum. These dangers are—(1) omission of part of the tissue, (2) confusion in tying the wrong ends, (3) uncertainty as to whether the ligatures are locked, (4) division of the tissue too near the ligature, (5) tedious loss of time. The trident is used thus:—The tissues are crushed in a kidney clamp and cut off flush. The trident is then passed below the clamp, transfixing tissue in three places. A yard and a half of catgut threaded on a needle is then passed through the eyes of the prongs. The trident is then withdrawn and the four ligatures are secured with Spencer-Wells’ forceps before the trident is cut clear. The ligatures are then tied and the other end cut as may be desired. Catgut may be safely used instead of silk, and the drawbacks of the latter avoided.
Dr. W. Winslow Hall, President, in the Chair.

Clinical Evening.

Dr. Herbert Tilley showed a man, aged 49, upon whom he had operated five and a half years ago for squamous epithelioma of the right vocal cord. The only symptom for the relief of which the patient applied to the hospital was “hoarseness” of two months’ duration. Laryngoscopic examination revealed a well-defined pale nodule occupying the anterior two-thirds of the right vocal cord. It was the size of a small horse-bean, and surrounded by a slight zone of congestion. The vocal cord upon which it grew was motionless in phonation. This fact, coupled with the appearance of the growth, determined the diagnosis of epithelioma. There were no enlarged glands in the neck. The operation consisted of a preliminary tracheotomy, followed by insertion of Hahn’s tampon cannula in order to prevent the blood passing into the lungs during the operation. The thyroid cartilage was divided in the middle line, and the halves held apart while the diseased cord with the ventricular band was completely dissected out. Finally, the halves of the thyroid cartilage were brought into accurate apposition by a cat-gut stitch, the external wound was sutured for three-quarters of its length, and the cannula removed from the trachea. The patient made a rapid recovery. The chief interest in the case was (1) hoarseness was the only symptom of such a grave disease; (2) the excellent voice which the patient now possesses; the place of the original vocal cord has been taken by a cicatrised band forming a sort of fixed false cord. Dr. Tilley laid stress on the importance of an early diagnosis in these cases.

Mr. Atwood Thorne would have liked to hear more of the microscopic results.

Dr. Wilfred Harris showed a man, aged 40, who three years ago fell a distance of about four feet on to his left shoulder, causing immediate paralysis of his arm. This was followed by a wasting of the deltoid, infraspinatus, biceps, brachialis anticus, and supinator longus, and by anesthesia of the thumb and index finger. No improvement occurred after treatment by galvanism. An operation by Mr. Warrendon in June last, on the upper roots of the brachial plexus, showed that they were buried in scar tissue. This was cleared away by stimulation of the roots by faradism showed the fifth root to be quite destroyed, while the sixth root gave good reactions. The fifth nerve was then cut across, and tunneled into a nail made in the sixth root. Immediate improvement resulted in the anesthesia of the thumb and finger. The galvanic reactions of the affected muscles have also since improved.

Mr. P. L. Daniel suggested transplantation of muscles as a more rapid method of recovering power in the limb.

The President asked if the man was likely to recover complete power in the limb.

Dr. Harris replied that muscular power might begin to return after six months. If, after regards transplantation, the deltoid was the most important muscle affected, and could not possibly be benefited by such an operation.

Mr. Laming Evans showed a case of spin bifida in a child, aged 3, involving the third, fourth, and fifth lumbar vertebrae and the whole of the sacrum. The swelling measured 12½ ins. round the base, and was of soft consistence except at its more medullated mass was felt. A sketch showed that this corresponded with the situation of the third lumbar vertebra, and Dr. Evans suggested that this was the spinal process and lamina of that vertebra, which had fused, and was in contact with the sacrum. The skin over the swelling was normal, and a well-marked umbilication was present in the upper part. Control over the bladder was absent. Associated with the trouble was a talipes equino-varus, involving both feet, of congenital origin. The electrical reactions of the muscles of the legs were normal. The skin of the feet was atrophic. Mr. Evans considered the case to be one of misalignment of the coccyx, and recommended no operative interference, except for the correction of the deformity of the feet.

Mr. Jaffrey said that operation in such a case was useless; the swimming should be protected by a proper, fitting plaster.

Mr. P. L. Daniel suggested arthrodesis on the ankle and knee-joints, so as to fix the joints and enable the child to walk.

Mr. Evans replied that, as there was good muscular power in all the muscles of the leg, and as the child had already walked upon her feet in the deformed position, arthrodesis did not seem called for. The child would be able to walk well with a plantigrade foot after the equino-varus deformity had been corrected.

Mr. Laming Evans also showed a woman, aged 21, with double pescavis and other deformities of the feet, which had existed as long as she could remember. No history of an infantile paralysis could be obtained. There was marked atrophy of the muscles of the right calf. All the muscles of the legs responded to faradic stimulation. The knee-jerk was slightly increased on both sides. Situated over the eleventh and twelfth ribs on the left side was a swelling, which was freely movable, tender to touch, and not attached to the underlying tissues; any definite pelvic space. Hyperpneusis was absent. Mr. Evans suggested the possibility of the swelling being connected with the meninges, and that the condition of the feet was dependent upon some spinal cord mischief of congenital origin.

Mr. Jaffrey said that the swelling in the back might be a spina bifida, a bursa, or fat. If Mr. Evans wished to determine which it was, he must operate.

Mr. Sydney Scott suggested that the swelling might be an old sebaceous cyst. He also thought that the deformity of the feet might be due to osteitis.

Mr. P. L. Daniel showed a man suffering from tuberculous arthritis, with a perforating ulcer at the base of the second and third toes, causing absorption of the third phalanx. He called attention to the fact that cases of untreated mild syphilis, and cases of "soft sore," are frequently followed by tubercles and ulcer many years after infection. He thought that "soft sores with tendency to spread, to infect by contact, and to produce enlargement of the glands, and considerable aching are all probably truly syphilitic, and should be so treated. Malignant change in perforating ulcer is rare; and this fact is not in accord with the idea that nerve control is a great factor in cancer distribution or causation. The loss of nerve control in perforating ulcer in association with the chronic nature of the wound should lead to frequent malignant change on the "nervous theory."

Dr. F. Jaffrey said that treatment by oxygen, obtained by applying peroxide of hydrogen for half an hour daily. At other times the ulcer should be protected with boric acid.

Dr. Wilfred Harris considered these ulcers to be not merely due to pressure, but of trophic origin.

Mr. Laming Evans suggested removal of the ulcer and necrosed bone, as thereby relapse is more likely to be avoided. He considered that the trophic element entered largely into the causation of the abdominal contents. In the absence of Mr. Crisp English, no notes on the case were forthcoming.

Mr. J. C. Horsley, R.A., the father of Sir Victor Horsley, died at his home in Kensington, on October 18th, at the ripe age of eighty-six.
THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.
MEETING HELD FRIDAY, OCTOBER 16TH, 1903.

Mr. Clinton Dent in the Chair.

Mr. R. Clement Lucas related the particulars of a case of strangulated hernia in an infant, aged 28 days, on whom he had successfully operated. Two days before admission the child had been seized with a sudden screaming fit, and the right side of the scrotum was then for the first time noticed to be enlarged. Persistent vomiting and constipation soon followed. At operation the hernial sac was found full of a dark yellow fluid, and, to contain a considerable quantity of blood-stained serous fluid, while a small knuckle of purple intestine was strangulated by the neck of the sac. He summed up the symptoms peculiar to this affection in infants as follows: (1) The onset of the strangulation is marked by violent and persistent screaming; (2) a tendency to suppression of urine as well as constipation is present; (3) rapid effusion of serous fluid takes place into the sac, and then into the general peritoneal cavity subsequently; and (4) rapid collapse occurs.

Dr. Skelding (Bedford) referred to a somewhat similar case in an infant seven weeks old on whom he had recently operated. In operating he noted that the incision from the opposite external ring, and carried it outwards and upwards towards the crest of the ileum. The advantages were (1) easier manipulation without drawing up the testis, (2) less friction on the wound by the truss, and (3) the dressings were less liable to become soiled.

Mr. Thomson Walker agreed that a diagnosis of hydrocele might be made in such cases, owing to the tendency of the air to escape. Mr. Lucas had pointed out that he related a case in which the opposite mistake was made. A child developed a scrotal swelling, accompanied by vomiting, pain, and constipation, and a diagnosis of strangulated hernia had been made. He could not agree with this diagnosis and gave it as his opinion that the case was one of acute hydrocele of the tunica vaginalis, which proved to be correct.

Mr. H. H. Chaldecott read a paper on the employment of ethyl chloride as a general anaesthetic. He described the method of administration, preferably by Ormsby's ether inhaler (1) in single dose cases, where, after anaesthesia is induced, the mask is removed and the operation is performed without any further administration; (2) in more prolonged cases, where the administration is continued during the operation; and (3) in cases in which anaesthesia is induced by ethyl chloride and continued by ether and chloroform. He claimed for ethyl chloride that it was the best known anaesthetic for short operations upon the mouth, throat, and nose, and that it was very useful, especially in the case of children, as a preliminary to ether or chloroform. At the same time it was a powerful anaesthetic, and the patient should be carefully prepared beforehand, as in the case of other anaesthetics.

Mr. Atwood Thorpe said he had found ethyl chloride very convenient, but not always without drawback, certainly with a sudden patient whom had been insufficiently anaesthetised, and in another case severe vomiting had followed, although this possibly was not due to the anaesthetic.

Dr. Goodinson said he had had considerable experience of ethyl chloride in ophthalmic outpatient work, and was more than satisfied with it. He had never witnessed any untoward symptoms, and vomiting, though thought, was generally due to an overdose of the anaesthetic.

Dr. Porter Parkinson read a note on paralytic chorea. The patient, a boy, aged 10, suffered from hemichorea with almost complete paralysis of the affected side, while the involuntary movements were not well marked. He had evidence of miliary disease. The diagnosis lay between hemiplegia with ataxy and hemichorea, and the facts that the knee-jerks were normal and equal on the two sides, and the plantar reflex was extensor in type, seemed to support a diagnosis of chorea. This was confirmed by an increase in the activity of the choreic movements and the gradual but complete recovery of the patient.

Dr. Purves Stewart referred to the three elements in chorea—namely, involuntary irregular movements, muscular weakness, and ataxia on voluntary movement. Sometimes the muscular weakness swamped the movements, and the result was the so-called 'paralytic chorea.' He discussed the immunity of infants from chorea, and ascribed it to the fact that they had not learned the pantomimic gestures expressive of emotion.

Mr. J. Jackson Clarke read a paper on the association of certain deformities with affections of the throat. He had come to the conclusion that hyperplasia of the adenoid tissue in the nasopharynx and throughout the body was as characteristic of rickets as the hyperplasia of the epiphyses. Cough in children was associated with skeletal changes and throat affections. After the surgical treatment of such affections he thought that medical measures were also required to complete the cure.

Dr. Percy Lewis was glad to hear the expression of views which he had held for many years. He could not agree that adenoid hypertrophy was always due to rickets, and thought that fatty nasal catarrh from neglected catarrh was the cause in many cases.

Dr. C. W. Chapman expressed his regret at hearing uric acid brought in as the cause of still further troubles.

Dr. Macalister (Liverpool) recorded a case of severe gastro-intestinal catarrh in a child, aged 4. The illness had apparently been provoked on two successive years by the changed feeding of the cows from which the milk was obtained, the time of onset being on both occasions when the cows were turned out to pasture. A remarkable feature of the case was the enormous distension of the abdomen, which diminished greatly during the night but recurred after the first meal in the morning. Gradual improvement followed the exclusion of milk from the diet, with the employment of suitable drugs.

SPECIAL ARTICLES.

BRITISH SANATORIA FOR CONSUMPTION.—XVII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE WOODILLE SANATORIUM OF THE GLASGOW DISTRICT ASYLUM.

During recent years, attention has been prominently directed to the prevalence of pulmonary tuberculosis in public asylums, and several important papers and reports have dealt with the question. (a)

Investigation seems to have clearly indicated that phthisis is prevalent in institutions conducted for the relief of patients under the subject of mental derangement to an extent which calls for urgent measures of reform. There is reason to believe that a very large number of

cases of phthisis have acquired the disease after their admission to the asylum. The special causes for this frequency of consumption in asylums seems to arise from overcrowding, with insufficient day, and especially night, cubic space allowance per patient; inadequate amount of time spent in the open air; defects in ventilation and mismanagement in heating arrangements; uncleanly habits of the patients; faulty dietary; neglect of suitable exercise; and lack of strict education in hygienic procedures.

The report issued by the Tuberculosis Committee of the Medical-Psychological Association of Great Britain and Ireland contains various recommendations made with a view to the prevention of consumption in asylums, among them being—the thorough investigation of all cases with the object of securing an early diagnosis of phthisis; isolation of tuberculous cases; limitation of the size of asylums; the arrest of overcrowding; increase in the cubic capacity of space allowance, both for day and night accommodation; the restriction of the number of the beds in dormitories; improvement in the means for providing free natural ventilation; increase care to prevent promiscuous spitting; more careful supervision of dietary; the construction of special hospitals and sanatoria with adequate and suitable surroundings for the segregation of consumptives and their treatment in accordance with hygienic principles; and failing the establishment of special sanatoria, the provision of temporary isolation hospitals or special wards and air- ing courts set apart for this purpose.

Sanatorium—South.

We believe it is not generally known that the Glasgow Lunatic District Board, acting under the guidance of the able medical superintendent of Woodilee Asylum, Dr. Hamilton C. Marr, has won the distinction of occupying the pioneer's position among British institutions for the care of the insane in providing a fully equipped sanatorium for their tuberculous cases, where treatment in accordance with the best modern methods is being very successfully carried out. We have therefore paid a special visit of inspection to the Consumption Sanatorium at Woodilee. Although perhaps somewhat outside the scope of these articles, we consider the movement initiated by the Glasgow authorities so epoch-making that we have no hesititation in including a short description of their newly-established Sanatorium for Insane Consumptives.

It is said that the mortality from pulmonary tuberculosis in asylums is ten times that occurring in the general population. The experience of Woodilee Asylum goes far to confirm such an opinion. Out of seventy-two cases in which a post-mortem examination was made there was evidence of active tuberculosis in fourteen, or 20 per cent. Dr. Marr states that in the asylum previous to the erection of the sanatorium the crowded condition of the warm day-rooms and large dormitories placed patients under conditions most advantageous for the spread of the disease. The fact that non-phthisical patients had to associate with phthisical ones who, moreover, took no precaution to prevent dissemination of sputum, was accountable for the extraordinary prevalence of consumption.

The new sanatorium is a model of efficiency. It has been built by Messrs. Spiers and Co., of Glasgow, and is constructed of their special patent building blocks. The buildings are of wood and iron, constructive materials which, on account of their comparative cheapness and the prevalent idea that structures intended for consumptives should not be of too permanent a character, seem to be well selected. After carefully considering the construction of the sanatorium, we are of opinion that the risks from fire need not be considered as serious, although we fear, after recent experiences, the English Commissioners might hesitate to pass plans for a building such as that at Woodilee. The sanatorium consists of three separate blocks connected by open corridors with a central administrative department. The ward system has been adopted, as, indeed, was essential, considering the class of cases to be treated. Provision has been made for sixty-two cases. No ward contains more than twelve beds, and each ward is well exposed to cross ventilation. The windows have open fanlights at the top and also open out into verandahs which run round the sides of each block. The beds can thus be easily wheeled from the wards on to the verandahs. All the wards are on the ground-floor. As already indicated, the structure of the building is of corrugated iron and wood, but having a brick foundation. The heating is by water under low pressure.

Great care appears to be exercised in the admission of patients to the sanatorium. No case is passed unless presenting distinct evidences of active tuberculous disease. The patients are kept as far as possible in the open air, and even in the most inclement weather the windows are not closed. The cubic space allowance in the wards is 1,500 feet for each person. We were much impressed by the strict discipline maintained. A comparatively large nursing staff is, of course, necessary, but a casual visitor would find but few evidences that the sufferers were also the subjects of mental derangement. Dr. Marr has adapted the Australian hammock bed for use in the open air, and we were struck with the peculiar advantages offered by it for the treatment of individual cases.

The whole of the sanatorium has been most judiciously furnished, and allows of the ready maintenance of perfect cleanliness, and at the same time the safety and comfort of the patients are secured. Many of the contrivances are distinctly ingenious, as, for instance, the provision whereby medicine cupboards close automatically.

Treatment is conducted in accordance with the best modern methods. Much care is given to the dietary. There is also a well-equipped electrical room where high frequency currents and X-rays can be employed. Hydrotherapeutic measures can also be used. Careful records are kept of every case, and the whole management indicates constant oversight directed by a strict scientific spirit.

Dr. Marr informed us that the sanatorium has already fully justified its establishment. Many noteworthy results have been obtained. It is interesting also to find that patients who would exercise no precautions
in spitting while in the asylum when removed to the sanatorium have been successfully brought to use their spittoons both in the wards and in the grounds.

The asylum is quite distinct from the asylum proper, although, of course, built upon the same estate, and there is abundant open ground in the immediate neighbourhood where suitable cases may enjoy appropriate exercise.

As further evidence of the enlightened and truly progressive spirit manifest at Woodilee, we should like just to mention that a most admirable reception house has recently been built. It consists of two wards and six bedrooms, and can accommodate twenty patients, ten of each sex. Its arrangements are devoid of all asylum features. It is staffed by female nurses, and is under the charge of a trained hospital nurse. Every case on admission is studied in this reception house. As the Commissioner in Lunacy has wisely stated, "The comfort, rest, skilful treatment and good nursing which newly-admitted patients receive in this house are most favourable to the early recovery of the curable, and to the well-being of those who are incurable."

We have nothing but praise for the Woodilee Sanatorium. It is an experiment which has fully justified itself by its success. We commend Dr. Hamilton Marr's reports on its management to all practical alienists, and we think that all asylum committees would do well to make themselves acquainted with the very excellent measures which have been so admirably carried out by the Glasgow Board for preventing and arresting pulmonary consumption in the insane.

Woodilee Asylum is a little over a mile from Lenzie station, which can be easily reached by a short railway journey from Glasgow.

We understand that another sanatorium has been provided at the other asylum under the Glasgow Lunacy District Board at Gartloch, with Dr. W. J. Parker as medical superintendent, but this we have not as yet inspected.

France.

PARIS, October 25th, 1903.

Congrès Francais de Chirurgie.

The Annual Surgical Congress was held this week in Paris. The first subject treated was exclusion of the intestine. M. Hartmann said that the term exclusion of the intestine was differently understood.

By some it was applied only to operations where a portion of the canal was completely isolated by two sections; others, on the contrary, included under the term all interventions by which a more or less large portion of the intestine was detached from its ordinary circuit. He himself adopted the first idea, that of complete removal of a portion of the intestine.

Exclusion of the intestine can be either unilateral or bilateral. In the former the intestine is cut across above the portion desired to be excluded and the upper end anastomosed to a segment below the excluded portion, while the lower end of the section is closed, or, on the contrary, left open so as to form a fistula.

Bilateral exclusion, two sections of the intestine, one above, the other below the portion to be excluded, and the central end anastomosed with the peripheral end. The mortality of exclusion was 13 per cent. As to the indication of the operation it would be found in tumours, inflammatory strictures, and lesions of the intestine complicated with fistula. As regards cancer, it was proved that life was not more prolonged by exterior-anastomosis, which was generally sufficient to ease the pain. With this reserve, exclusion of the intestine constituted a real progress, and it afforded a remedy to a series of cases hitherto inaccessible to surgical treatment.

M. Roux, of Lausanne, said he practised eighteen times exclusion for cancer; three of the patients died, while the lives of two were prolonged two years. In eleven cases of resection of the appendix a froid he executed exclusion to prevent possible complications, and each time with success. For many other affections he practised also the operation of exclusion, and out of a total of forty-eight patients he only lost six.

M. Tenenat (Montpellier) said that for his part he resorted in three cases of hypertrophic tuberculosis of the caecum, and all recovered. But it was certain that where adherences were considerable the operation was frequently impossible, and in such cases exclusion constituted a precious resource. In a case of that kind he performed unilateral exclusion, anastomosing the ileum and the sigmoid flexure with excellent results.

M. Montprofit had recourse with success in four cases of inoperable cancer of the caecum to a double implantation of the ileum in cutting it at a certain distance from the caecum, then anastomosing it outside the tumour with the upper end of the small intestine, and subsequently uniting the distal end of the sigmoid flexure. In this way a cutaneous fistula was avoided, and the total evacuation of the fecal matter into the intestine ensured.

Jacksonian Epilepsy.

M. Delbet (Paris) said he was called to a patient who was in a semi-comatose condition from repeated attacks of Jacksonian epilepsy, which had commenced nineteen years before, and had increased to as many as 200 seizures a day. He performed trepanning, and the patient recovered. In referring to the modus operandi, the speaker said he had collected a series of 130 cases of trepanning for Jacksonian epilepsy, and after a careful analysis he had come to the following conclusions:—If there existed a marked depression of the cranium the trepan should be applied to that spot. The incision of the dura mater was not indispensable, but it was preferable, however, to incise it in order to be able to observe the condition of the brain. Where no depression existed the skull should be opened according to the method of Doyen (a large strip of the bone), so that the membranes and the brain be sufficiently exposed.

BERLIN, October 24th, 1903.

Germs in Accidental Wounds under Dry Aseptic and Moist Antiseptic Treatment.

Dr. Carl Goutemann has an article on the subject in the Archiv. f. d. chir., 70, 2, in which a comparison has been made between the two different methods of treatment of accidental wounds. The conclusions arrived at after comparative investigation are as follows:—

1. No antibacterial effect can be proved to follow the application of most antiseptic dressings to wounds.

2. The germ contents of non-purulent accidental wounds are more increased by moist antiseptic dressings than by dry ones.

3. In accidental wounds preference is to be given to iodolarm gauze, as it exercises a decisive effect on the micro-organisms by its property of taking up the wound secretion and arresting haemorrhage.

4. Moist dressings further the development of eczema and abscess of hair follicles by maturation.

5. Moist dressings are better means of an effective preventive of suppuration in such wounds.

6. In suppurating wounds dry dressings effect a quicker diminution of germs than moist ones.
7. In phlegmonous inflammations dry dressings favour the diminution of the germ contents (aseptic gauze and iodiform gauze).

8. Many accidental wounds heal without clinical signs of infection in spite of the presence of large quantities of germs.

The Deutsche med. Zeit., 7,603, has a reference to a paper on "Uremia," by Dr. A. Bickel, of Göttingen. The most recent methods of investigation (determination of the freezing-point of the urine and its electrical conductibility) are touched upon, and the author goes on to point out that the results hitherto obtained in these investigations, in the author's opinion, are the first that have given really useful results, and even a cure free from objection, in regard to our knowledge of uremia. Nephritic urine is characterised by a low degree of concentration; the urines of both acute and chronic nephritis are alike in this. According to Lindemann a freezing-point of even —1° C. is characteristic of this urine, whilst for normal urine the freezing-point is —1° to —2° C. The lowering of the molecular concentration of the urine does not necessarily run parallel with a heightened molecular concentration of the blood, as might perhaps be expected. The blood may in nephritis keep its normal concentration for a long time, but it is often found concentrated, and, as Kasranyi has shown, it often displays a highly abnormal concentration. The freezing-point of normal human blood is, as is known, about —0°56° C. Koranyi found —0°54° to —1°04° C. in cases of nephritis. If these were expressed in percentages of a solution of salt, —0°56° C. would correspond with a 0°93 per cent., —0°54 with 0°91 per cent., and —1°04 with a 1°09 per cent. solution. Lindemann found in cases of nephritis that this increase in the molecular concentration of the blood comes to pass especially when uraemic conditions arise. He goes so far that he declares the heightened osmotic pressure to be the general expression of the uraemic disturbances, and assumes that the major part of the symptoms exhibited may be satisfactorily explained by it. But this is not sufficient alone, a knowledge of the kind of concentration is necessary to explain the symptoms on the part of the nerves. It is not the concentration itself that sets up the symptoms, but the bodies causing the heightened concentration that are responsible. The author's experiments on animals have led him to believe that these bodies are not so much bases, acids, or salts, as other molecules, especially organic bodies, products of destructive tissue change.

He also discusses the subject of venesection in uremia. The earlier belief that the favourable effect of venesection in uremia was due to a change in the physico-chemical relations has been shown to be incorrect. It has been shown that neither venesection alone, nor even in combination with saline infusion, changes the concentration of uraemic blood, but that its viscosity is changed. By venesection and saline infusion the friction of the blood on the walls of the blood-vessels is diminished, and this is equivalent to diminished labour for the heart—a point of importance in very serious cases. Again, in uraemic conditions, when the circulation is imperfect, there is a tendency to stasis in large quantities of blood corpuscles, and the concentration of uraemic blood is diminished; but this is a reverse effect. Perhaps this stasis of the erythrocytes goes hand in hand with the falling blood pressure, which, when excessive, is a bad prognostic sign and points to cardiac paralysis.

The Corporation of London have adopted a series of regulations for the better sanitary control of the milk supply of the City.
be taken into account when discussing the etiology of the disease, and that maize alone is not the real cause. To sustain the argument of maize being the cause, Lombroso points to the long use of lead, mercury and alcohol as injurious agents that can be borne for a very long time without any seeming injury, hence eating the same bread and drinking the same water will not affect all alike.

The disease by some has been ascribed to heredity just in the same way as Kussmaul holds that the children of the operatives engaged in mirror manufacture have mercurial children. There are many cases on record where no maize has been used, yet the patient suffers from the disease. Lombroso brings forward the symptoms as proof that diarrhoea, paresis, and desquamation of the skin similarly occur in paralysis, uremia and alcoholism. His experiments with diseased maize are also unfortunate, owing to the concentration of other salts in the experiment; besides, the maize used contained Oidium lactis, Penicillium glaucum, Mesentericum vulgaris, which contain toxins, and for which he makes no allowance.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

IRREDUCIBLE HERNIA WITH HYDROCONE OF THE SAC.

—Mr. Battle operated on a young man, aged 20, who presented a rather unusual condition on the right side of the scrotum; he had been sent into the hospital for radical cure of a hernia; he had noticed a swelling on the right side of his scrotum for a period of three weeks only, and he could not account for it. It was much the same size on admission as it had been when first noticed, and he did not know whether it had commenced above or below. The right side of the scrotum presented an enlargement the size of a duck's egg; this was pear-shaped in outline, the upper part causing a swelling in the inguinal canal; the lower part was rounded, and the testicle did not cause any projection on its surface; the lower part of the swelling was fluctuating and translucent, whilst the upper part was quite solid to the feel. There was no impulse on coughing. The diagnosis which was made was one of irreducible omental hernia with an accumulation of fluid in the congenital sac. At the operation it was found that this diagnosis was correct, for the neck of a congenital hernia sac was completely blocked by the adherent omentum, and a large quantity of fluid of a yellowish-brown colour escaped from the lower part of the sac. The operation performed was that by Bassini's method, and after the covering of the canal had been divided, another incision was made in the neck of the sac, which opened the peritoneum above the adherent omentum; this was then ligatured in sections and returned into the abdomen, after which the upper part of the sac with the adherent portion of omentum was removed, the opening in it closed with continuous purse-string sutures, the ends of which were tied together. The conjoint tendon and Poupart's ligament were sutured behind the cord with silk, after which the remainder of the operation was completed after Bassini's method. No sutures were put into the lower part of the sac to form a new tunica vaginalis, as this is no longer considered necessary. Mr. Battle said that the diagnosis rested in the first place between (1) hernia simply irreducible and containing omentum and intestine; (2) funicular hydrocele; and (3) irreducible hernia with hydrocele of the sac. The history, he thought, was no help in diagnosis, for in the patient was very unobservant, as it was very unlikely that such a condition could have developed in so short a time. When careful examination had shown that the softer part of the swelling was translucent and fluctuating, it did not require the proof of dulness on percussion to show that a considerable amount of fluid was present, and although the funicular hydrocele sometimes extends up to the internal ring, causing the swelling along the inguinal canal, and has dulness on percussion, fluctuation can be obtained from one end to the other; here the fluctuation stopped towards the upper part of the scrotum and was replaced by solid structure. The additional question which presented itself, he pointed out, was whether this was a case of hydrocele of the tunica vaginalis and a hernia, but the fluid came directly up to the omentum and caused a bulging at its upper end, which was supposed to correspond to the width of the neck of the sac, widened by the presence of the omentum. A congenital hernia showing itself at the age of this patient usually, he remarked, announces itself in a very violent and painful manner, the patient being extremely ill and strangulation one of the earliest symptoms. Union took place by first intention, and the patient's recovery was uninterrupted.

TOTTENHAM HOSPITAL.

ABDOMINAL MYOMECTOMY AND HYSTERTOMY.—Dr. ARTHUR GILES operated on a married woman, aged 49, who had been admitted in case of constant haemorrhage, which had been going on for some months. On examination under an anaesthetic a fibroid myoma was found occupying the anterior wall of the uterus. The question of dealing with the case through the cervical canal was considered, but the operator came to the conclusion that the myoma could not be satisfactorily removed in that way. The abdomen was therefore opened. When the uterus was brought into view it was found to be the seat of a solitary myoma about the size of a hen's egg, occupying the anterior wall. A vertical incision was made over the tumour, which was shelled out without any difficulty. The bed of the tumour was next incised in order to open up the uterine cavity. The mucosa was found greatly thickened, and was removed by curettage carried out through the abdominal wound. A pair of forceps was passed down through the internal os into the vagina to dilate the cervical canal. The uterine wound was then closed by a series of mattress sutures followed by a continuous suture of fine silk to bring the edges together. The uterus was attached to the anterior abdominal wall by means of two silkworm-gut sutures, and the abdominal wound closed by the usual three-layer method. Dr. Giles said that this might be regarded as a typically conservative operation, since only the diseased structures were removed, and the otherwise healthy organs left behind. Formerly, he remarked, he would have approached such a case through the vagina, and after dilating the cervical canal an attempt would have been made to enucleate the myoma by cutting through the uterine mucosa; only those who had attempted this proceeding could realise how unsatisfactory it was; it was generally accompanied by a considerable amount of bleeding; there was a definite risk of perforating the uterus if the outer surface of the tumour lay close under the serious cost of that organ; and with a tumour the size of the present one either it had to be removed piecemeal or the cervix would have to be divided up to the internal os; further, it had happened to him to find a myoma so firmly imbedded that it could not be dragged out without unjustifiable force, so that he had had to be content with freely opening up the capsule and waiting for the uterus to expel the myoma later on. The present operation, he said, was in every way a contrast; there was practically no bleeding, the
The Medical Press and Circular.

LEADING ARTICLES.

OCT. 28, 1903.

The circumstances of a recent tragedy have brought into striking relief the amateur and bungling methods of the police engaged in the affair. For the last two months the public interest has been riveted on the mysterious disappearance of a young lady doctor from a London hospital. With the facts of the case we are not here concerned, for the present, at any rate, but certain proceedings on the part of the police are so reckless in their defiance of ordinary medico-legal rules as to demand a somewhat full discussion in the interests of the general community. As most of our readers are probably aware, the body of the missing lady was found in a wood in Richmond Park, in the neighbourhood of London. The discovery was made accidentally by some boys who were trespassing in the wood, which is carefully preserved for game, in search of chestnuts. When the police were informed of the matter they went to the spot, a dense overgrown copse, and proceeded to cut a path through the tangled undergrowth for the removal of the remains, which they ultimately effected at midnight, so it is reported, with the aid of bull's-eye lanterns and a single carriage lamp. That is the circumstantial account given in several leading journals, and its correctness does not appear to have been officially disputed. At the time of the removal of the body from the copse there seems to have been no suspicion that the remains were those of the missing lady doctor. This is the more remarkable inasmuch as a London journal, by independent inquiries, traced the lady in question to the neighbourhood of Richmond. So careless or sceptical, however, were the police as to the value of this clue that the adjoining public park was searched only in a perfunctory manner. A really close and systematic search would almost infallibly have discovered the body some weeks ago, when the cause of death could have been traced with far greater certainty than is now possible. So little impression does the journalistic clue appear to have made upon the authorities that it did not even occur to the local police that the remains might be that of the missing lady. In any case, however, the discovery of a dead body in a public park would demand the exercise of a due amount of precaution in view of the possibility of criminal complications. As it was, the police found a corpse in an advanced stage of decomposition lying in a wood with the head at some distance from the body. They apparently made no attempt to examine the immediate surroundings for footprints, weapons, and other circumstantial evidence, but trampled under foot and destroyed what might have been invaluable evidence. There was no immediate hurry for removal, as the body was already decomposed, and the examination of surroundings could have been conducted in a leisurely and systematic fashion in the broad light of day. As a matter of fact, some hours later a further visit to the spot furnished evidence of identification of the body. Since that time an empty medicine bottle has been found in the plantation, and near its boundary fence a surgical scalpel. The discovery of these things is significant, but we are not here concerned, as already mentioned, with the way in which the unfortunate lady came to her end. Our point is that the police, in not preserving intact and most carefully examining the surroundings of the body, have displayed an incompetence that is well-nigh incredible in this age of advanced science. Every medical man is taught that on being summoned to a dead body, after first ascertaining that life is extinct, his first duty is to note the position of the body, with every possible detail directly or indirectly connected therewith. Why should not the police be acquainted with so elementary a precaution? The duties of
the police constable are manifold and onerous, but there is no reason that he should enter upon them as absolutely uninformed as to the most obvious principles that should guide him in the exercise of his calling. As a matter of fact, we are of opinion that the police force of this country should have a thorough training in medico-legal matters before being entrusted with the discharge of its onerous and responsible public duties. In offering these criticisms it should be clearly understood that we in no way fail to recognise the many claims of an admirable civil force to the admiration and gratitude of the community at large.

THE DIFFICULTIES OF REFORM.

In our last issue our readers may remember that we published an abstract of an address delivered by Mr. Tobin, Surgeon to St. Vincent's Hospital, to the students of the hospital, in which the speaker dwelt on the present condition of the Poor-law Medical Service, and concluded with the advice to the students "to let the Service at present alone." This very excellent advice doubtless appeared to many to be a set-off to a rather contrary and suddenly expressed opinion delivered by Mr. Tobin's colleague, Mr. M'Ardle, some years ago on the occasion of the annual dinner of the hospital, and to represent the true feeling of the staff of St. Vincent's Hospital. Few people, and certainly no medical man, who had the welfare of the Poor-law Medical Service at heart could dissent from Mr. Tobin's advice, advice which has been iterated and reiterated in our columns, and in those of other medical journals and the Lay Press. It seems, then, to be a pity that, in the face of Mr. Tobin's speech, Mr. M'Ardle should on a more recent occasion—again that of the St. Vincent's dinner—have sought a second time to decry the efforts of Poor-law medical officers to obtain the reform of their Service. On this occasion it was the suggestion that the Poor-law Medical Service should be turned into a Civil Service that aroused his opposition. His answer to the question should this course, recommended by the Fer managh Conference, be adopted by the Government was "the simple word "No." The English Government were not such fools as to patch up things in Ireland, and to take away from the people the only vestige of power vested in the people three years ago, and any change would, in his opinion, be bad for the profession and for the people. Mr. M'Ardle is, of course, quite justified in expressing his opinion, but when he does so in opposition to the wishes of a representative body such as the Irish Medical Association, he should, we think, only do so for most sound and substantial reasons. Two questions occur to us which, we think, he should also have volunteered an answer. Can the present system of appointing medical officers be justified in any possible manner? Are the present conditions under which the medical officer works those to which a highly educated medical man should be compelled to submit? If Mr. M'Ardle can answer these questions in the affirmative, then, doubtless, he is justified in his opposition to the course, which, we venture to say, is the only capable of raising the Service above the petty bickerings of religion and politics. But can he do so? Is the story told by the then Mr. Horace Plunkett during the debate in the House of Commons on the Local Government Bill, of two dispansary medical officers, both of whom had been appointed on religious principles, and both of whom died of drink, a fiction of the imagination, or is it a sad fact, the result of the present system? If it is not true, we will substitute for it one which is, of a medical officer who was appointed some two years ago, who held office for six months, during which time he was rarely if ever sober, and who finished his career by being sentenced to penal servitude for pouring vitriol in a drunken frenzy over a sleeping man. God forbid that such men should be taken as a sample of the officers of the Poor-law Service—a body of men who are famous for their devotion to duty and their self-sacrifice. The question will, however, arise and cannot be shirked: how comes it that such men as those of whom we have told were appointed? The answer is a sad one—the majority of the electors were in their favour. Is not this a condemnation of the present system of election? Are others needed? How comes it that the ranks of what ought to be a public service are closed in one part of the country to exclude the students of one school, in another part of the country to all but the students of another? These questions must be faced by an advocate of the present system, and are those which, in justice to the members of the Irish Medical Association whose demands he condemns, and in justice to himself lest motives other than the desire of general professional advancement be attributed to him, Mr. M'Ardle should answer. Our columns are freely open to him.

THE PRE-EMINENCE OF SPORT.

The keenness of the instinct which leads to love of, and indulgence in, outdoor sports and pastimes is very rightly regarded as a pretty good index of the physical vigour of the individual. In the healthy young of both sexes the natural desire for romp and play soon manifests itself, which, as a result of the companionship and rivalry of school life, quickly assumes a more purposive and better organised form. No compulsion is needed in order to induce the average British boy or girl to take part in outdoor games, for, as a rule, their attraction is greater than that of the school-room. But here and there one comes across a timid child to whom the bustle and publicity of a round game is a positive source of pain, and who would be far happier spending the time in poring over a book. The greatest judiciousness must be observed in forcing these shrinking little ones to run and tear about against their will. In a few cases their unwillingness may be due to actual physical disability, when, of course,
they will require special supervision during playtime, while in others it approaches very closely a neurosis. This must be gently but firmly overcome. Happily, the number of these retiring and sport-detracting youths and maidens is far outweighed by those for whom the field and its pastimes are a source of healthful and never-ending pleasure. Those who sing the loudest about the physical degeneration of the race seem entirely to overlook the fact that our national games are played with so great a zeal by the youth of all classes now as ever they were. Indeed, it has been complained by some that too great a proportion of time is devoted to sports, especially in our public schools, to the threatened detriment of study and mental culture, and that there is a danger that the humorously satirical epithets of Kipling may be applied in all seriousness to the athletic champions of the present day. Like any form of amusement or indulgence, it is quite possible for anybody to engage in sport, whether this be football or fishing, cricket or cycling, to an exclusive and pernicious extent. Some outdoor games appear to exert a peculiar fascination upon certain natures, causing the individual to live almost entirely for that one thing, dreaming, thinking, and planning about nothing else. The desire to excel, to become a popular hero, when it has once taken possession of a youth of this description is fatal to his success at school, and should he be of an unusually unbalanced mind, his future career will be severely compromised unless moderation can be enjoined. It would, of course, be idle to suppose that, because a boy committed suicide on account of his being unable to go to a football match, this game possessed a greater demoralising influence upon schoolboys than other forms of outdoor sport. Nevertheless, this incident has given rise to a considerable discussion among teachers in Yorkshire, many of whom have admitted that football is in danger of becoming the pre-eminent topic of conversation among, and the sole aim of existence of, their pupils. We cannot believe that such an extreme and gloomy view is, or ever will be, the expression of the true life of the schoolboy of to-day who has generally more idea of getting on in the world than his teachers give him credit for. Granting that, in some instances, a little too much time is given to sport, it is surely better to run the slight risk of neglecting the pursuit of book-knowledge and to develop sound and healthy bodies, rather than foster a race of dyspeptic and enfeebled intellectual giants. It is physical staying power which tells in the long run in the battle of life.

Dr. O'Connor delivered the first of the lectures of the winter course held in connection with the Mount Vernon Hospital at 5 Fitzroy Square, on Thursday last. The lectures and demonstrations are held every Thursday, at 5 p.m., and are open to medical practitioners and students of medicine. A list of the forthcoming lectures will be found in our advertisement columns.

Notes on Current Topics.

Harvey and the College.

Every year there is an oration at the College of Physicians delivered by one of its Fellows in memory of William Harvey. Every year an attempt is made to discover some new phase in the history of his life, his character, or his discovery which will add to his fame and identify him more closely with the College. Some orations deal with what was known and was true; others with what was simply imagined, but not proved, before Harvey wrote his "De Motu Cordis." In every discovery the questions of what is quite original, and what has been more or less anticipated by others, are of primary importance. It is usually difficult for these questions to be settled. Of course, a strong personal feeling enters into the Harveian Oration; and what Harvey did for his College, or the College has done for him, usually forms no small part of the orator's address. This year the lines on which Harvey worked are chiefly considered, and the observations by which Harvey was led to the conclusions he arrived at: are claimed to belong to what we know as anatomy in its clear and simple meaning, six., the dissecting of the dead body. Vivisection or physiological and biological work, as we know that kind of work, was not the basis of Harvey's discovery. The problem he was dealing with was a mechanical one far more than a physiological one. It was a problem in which the physics of moving fluids, and of valves and pumps, had to be considered first and foremost, and into which the consideration of the construction of parts and their mechanical functions chiefly entered. Anyone who studies carefully the writings of Harvey will see that anatomy satisfied him in his view of the circulation. How far vivisection was resorted to as a source of evidence is another matter, and it certainly seems that it was forced upon him by the objections and requirements of incredulous or jealous opponents. Harvey's work was really a work of destruction; the clearing away of ignorance and falsehood, and the establishment of truth in their place. The discovery of a planet or a new-element has none of the odious associations of such a new idea or discovery as Harvey's. It raises no kind of more or less angry and violent opposition. Anything which disturbs the statu quo of the time is objectionable to so many that the disturber has an unpleasant time of it. So it was with Harvey. Why the followers of the great Oliver should have sacked his house, and treated him in the low scurrilous way they did should not be overlooked, and what may be expected from such a class may help us in the future. The vulgus profanum will always exist, and if it has power will always use it badly in matters that have to do with true science. It may be well for the College to hang out the banner of Harvey once a year and march along singing his praises. So far as that which Harvey left them in his will, not very much can be said, and certainly in the last year of his life there did not appear to be any extremely
warm feeling kept up between the College and Harvey. This annual laudation of John Hunter at one College and Harvey at the other has something puerile and contemptible about it, and certainly does not increase the reputation and character of those that encourage it.

**Latter Day Cures.**

If the passion for "seeking after a sign" was one of the distinguishing features of a certain race of individuals in ancient times, it is scarcely less characteristic of the people of the present day that they are continually "seeking after a cure." The natural desire to get well lies deeply in every breast, and forms one of the primitive instincts of man, so that, in one sense, there is nothing new in the principle itself. And yet, if we compare the relation which existed between the ancient physicians and their patients with the attitude adopted by the public of to-day towards its medical advisers, it cannot be denied that a change has, indeed, come over the spirit of the age. There is no need even to go back as far as the Middle Ages, for two or three generations will suffice to render manifest these altered conditions. The unbroken confidence and unquestioning obedience on the part of the patient are in danger of giving place to a half-amused scepticism and a relentless dissatisfaction. The value of old and trusted remedies are freely discussed and criticised in the papers and at the tea-table, more especially by those who make it a hobby to parade their pseudo-medical knowledge, and who consider themselves perfectly competent to advise everybody upon all matters connected with health. Such individuals consult one doctor after another, either for some real or imaginary indisposition, and, if the treatment prescribed does not happen to be exactly what they think right and proper, they are loud in their condemnation of Dr. A. when they next visit Dr. B. Happily, these people constitute only a small part of the physician's clientele, and they are only met with in certain quarters of society. Nevertheless, the tendency of many persons to take up with special modes of treatment, sometimes of a very doubtful kind, and to undergo this or that "cure," whichever happens to be in accordance with the latest fashion, does certainly exist, and it is matter which provides food for serious reflection. The rapid and perhaps undue growth of specialism in the ranks of the profession, the facilities which are still allowed by law for quacks to carry on their trade, the increased knowledge now disseminated among the general public about medical matters, combined with the all-pervading mercenary spirit of the present day, are all, doubtless, responsible for the rise and progress of many of these so-called "cures." In the majority it will be seen that the chief basis consists of the insistence by its promoters of the principle of the preponderance of mind over matter. The patient's faith must be exercised in the highest degree, no matter what the object presented to the senses be, whether light or darkness, grapes or water. There is hardly any substance in Nature, nor any habit of life, which, if taken or refused, indulged in or renounced, has not been credited with miraculous powers of healing. In one case lean meat must be rejected, in another no coffee must be taken under any consideration, in a third the body must be anointed with oil so many times a day. But in all, a firm belief in the efficacy of the agent employed is necessary to complete the "cure." Many of them, in certain diseased states, are positively harmful, as, for instance, hunger or fasting "cures," and cases are known of mitral disease in which the "rest-cure" was undergone with disastrous results. Physical culture is a good thing, and much to be sought after, but the indiscriminate use of gymnastics, vibratory movements and massage cannot but be condemned. Fads and faddists there will always be, even in medicine, but there is such a thing as carrying a fad to a dangerous extreme and jeopardising a life which, if it were placed under rational, scientific, and orthodox treatment, might be restored to health and usefulness.

**Medical Service in West Africa.**

The Colonial Office have recently issued a pamphlet dealing with the Government Medical Service in West Africa, which is of interest and importance to medical men who are desirous of joining the Service. The Medical Services of the different Colonies—Gambia, Sierra Leone, Gold Coast, Lagos, and Northern and Southern Nigeria—were formerly distinct and separate from one another. This, has, however, now been altered, and, with the amalgamation of the Colonies, the medical officer receives increased pay, and the conditions under which he has to carry out his duties are materially improved. Naturally, the Government also expect that the candidates that offer themselves for the Service must be fully instructed both in general medical science and especially in diseases peculiar to the Tropics. With this end in view they are in future required to undergo a course of instruction in the School of Tropical Medicine, either in London or Liverpool. This additional course will not, however, throw an additional expense on the candidates, as the cost of living and the tuition fees are paid by Government, in addition to a daily allowance of five shillings during the time the candidate is under instruction. Private practice is permitted in the Service, and the allowance of leave is good. The climatic objections to the Service are the most important, but these are being gradually in great part removed, now that a clearer insight has been obtained into the necessities of life in the Tropics. To men who do not desire to follow private practice in this country, these Colonies offer many attractions, attractions which, to our mind, go far to make the Service superior to the dreary drudgery and the unrequited toil of the Irish Poor-law Service or English club practice.

**The Virtue of Soap.**

The removal of the superficial dirt for which the human skin seems to possess a special attraction is one of those important personal matters which
demands the almost constant attention of every civilized inhabitant of the globe. Exactly how this shall be accomplished is immaterial, provided that it is carried out to the individual's own satisfaction and in accordance with the laws of health. Some degree of mechanical friction of the epidermis is a necessary part of the procedure, and some varieties of dirt found in the atmosphere of cities and large towns certainly need some emollient, saponaceous substance for its detachment, and for this purpose soap is most generally used. It is convenient, efficient, and makes directly for cleanliness. Although there are a few morbid conditions of the skin in which the use of soap may be contra-indicated, yet it is a substance which can be readily medicated, and thus it becomes of great service when it is desired to apply certain remedial agents to the skin. By its alkaline properties it removes a portion of the natural secretion of the sebaceous and sweat glands, and on this account its too free use has been considered by some, in all seriousness, to deprive the skin of its oily matter, and consequently to prevent it exercising an important function. This might be conceivably the case in those in whom the natural secretions are deficient, or in certain diseases of the skin. The custom of anointing the body with oil after bathing, so much indulged in by the ancients, is very little, if at all, practised in the present day, chieffly, no doubt, because very few people could spare the necessary time for the inunction. The idea that the use of soap is responsible for disease, which was expressed recently by a Colonial correspondent to the Times, is hardly one which will meet with acceptance, either by medical men or by the general public.

Formic Acid and the Muscular System.

It is a somewhat curious fact that, although formic aldehyde has found a place for itself in scientific therapeutics, yet formic acid is almost unknown as a remedy. However, in the seventeenth century it appears to have possessed a considerable reputation as a cordial, a stomachic and a diuretic, for it constituted the principal ingredient of a preparation then familiar as Hoffmann's "Vinegar of Magnanimity." With a view of ascertaining the effects of its internal administration, M. Célestin conducted a series of experiments upon himself the results of which he has recorded in the Lyon Medical. He took eight to ten drops of formic acid four times a day, diluted with Vichy water, so that a sodium formate was formed. At the end of a period of twenty-four hours he experienced a distinct feeling of muscular excitation with an increased capacity for performing violent or fatiguing movements. Such muscular efforts as walking up inclines were rendered easier of performance. In order to test this remarkable property of the drug ergographic records were taken and it was found that the instrument recorded an actual increase in the amount of muscular work done after taking the acid internally. The phenomenal capabilities of ants to perform work in proportion to their size has long been a subject both for admiration and conjecture, and it is suggested that their excretion of formic acid may be connected in some way with this property. At any rate, the sensation of muscular weakness after exertion was, according to M. Célestin, removed to a great extent. One other action of the drug is noteworthy, namely, its power to reduce arterial tension in the majority of individuals. It is therefore possible that there may be some future scope for formic acid in the treatment of disease, and that it may even regain something of its former reputation.

Scientific Faddism.

The advice recently given by Sir William Church on the dangers of "over specialization" might, we think, be extended to an even more dangerous class than the specialist who imagines his particular region the only one of importance, and acts on such principles. We refer to the man of science, who, completely captivated by one idea or truth, sees everything in support of his theory, and is blind to all else. The higher his position and the greater his reputation, the more danger is done. In the world of science we are afraid that Mr. Jonathan Hutchinson is at present a notable example of this frame of mind, as anyone reading his speeches and letters on leprosy must see and deplore. Even more "cranky," however, in his arguments is a well-known physician of Philadelphia, Dr. George M. Gould, who, having inundated the American press with his contributions on the subject of "eye-strain," has recently invaded the medical papers in these countries. Eye-strain is, we gather, the root of all evil. In exhaustive investigations into the ill-health of Darwin, Wagner, Carlyle and (a somewhat indecent proceeding, at least, in these countries, since he is still with us) Mr. Herbert Spencer, Dr. Gould proves up to the hilt by the easiest methods that a competent oculist would have made them the happiest of men. "If one looks out," he says, "over history there is seen to be no condition of human life wherein ametropia did not play a great rôle." Chorea, insomnia, the new woman, the tipping husband, the criminal, the truant schoolboy are all among its results. Truly eye-strain (worse Dr. Gould) has a great deal to answer for.

The Evolution of the Nurse.

The confidence which is reposed in the modern nurse by the physician, the great responsibilities which are entrusted to her, the high esteem in which she is held by patients, and the loyalty of her devotion to the duties of her calling, all make it hard to realise that she is the creation of the latter half of the nineteenth century. It is true that nurses, of a sort, have always existed wherever sick humanity needed tending, but though such women did minister to the suffering, they were, for the most part, densely ignorant and superstitious. It was not until that great and noble pioneer of nursing, Florence Nightingale, appeared that a real impetus was given to the cause and an "organised altruism" began to
flourish. Following the plan of the time-honoured introductory lecture delivered to medical students at the commencement of their career, Miss E. M. Fox, Matron of Tottenham Hospital, has, in "Our Profession," (a) sketched the relationship between the medical and nursing professions with such a nice exactitude that we would fain quote a few extracts therefrom. "The nurse's work supplies, as it were, the delicate embroidery, the silken though unseen lining, the patient, close-set stitches of the brilliant robes in which we love to see arrayed the best of our doctors. Hers is the profession that puts its soft hand into that of its friend and protector, medical science, and runs side by side with it, ever ready to help, never to usurp its rights and responsibilities, and becoming year by year more indispensable to our physicians and surgeons, who rely, with the sure confidence born of knowledge, upon the observant eye, the quick, capable hand and the tender sympathy of the trained nurse." There are some diseases in which the success of the treatment depends entirely upon the skill with which the case is nursed, and this applies especially to "the enteric patient who is wrestling hard for life, and whose feeble spark of vitality depends for its very continuance, perhaps, upon the measured ounce of nourishment being given exactly at the right time and in the right way." It is over such a bedside that the physician "listens to the accurately-worded report of the trained nurse, and knows he can trust to her to work intelligently and sympathetically for him in his absence." It would be well if this ideal relationship between the two sister professions, thus set forth, were borne in mind by every member of both. The Lymph Stream in the Spinal Roots and Cord.

The etiology of many diseases accompanied by or resulting in morbid conditions of the spinal roots and cord still remains enveloped in obscurity. A contribution of some value, however, in throwing light on possible channels whereby deleterious agents may reach these elements appears in the current number of the Review of Neurology and Psychiatry. Dr. David Orr shows that although bacteria have little tendency to spread along the nerves, their toxins can be carried in the lymph stream and exert their influence some distance from their source of origin. In the spinal roots the flow of lymph is upwards towards the cord. Of the lymph flowing up the posterior roots, the greater part passes into the posterior columns, while a small quantity flows into the lymphatic spaces of the pia-arachnoid covering the posterior and lateral regions of the cord. Where the fibres enter the cord, at which point their sheath and neurilemma are lost, they are specially vulnerable to the influence of toxins in the lymphatic system of the roots and meninges. This applies to both sensory and motor nerves. The course of the lymph stream in the posterior columns is ascending; and the lymphatic system of the posterior columns does not communicate with that of the lateral columns. It is clear that in the unmasking of the mystery which still envelops the causation of many forms of nervous derangement greater attention will have to be devoted to a systematic study of the paths of attack, and particularly to the course of the lymphatic channels.

Tabes in the Negro.

In seeking the solution of the problem of disease it is necessary to remember the far-reaching influence of race. Although of recent years much study has been devoted to certain infectious diseases prone to attack the negro we are still lacking data regarding the extent to which morbid conditions generally are influenced by racial peculiarities. This is particularly the case in regard to nervous diseases. Regarding tabes in the American negro but few trustworthy references are available, and therefore Dr. D'Orsay Hecht's recent conclusions in regard to this matter are of particular interest. It would seem that long residence with the white man has made the American negro anthropologically, physiologically, and pathologically different from his African ancestors. The constitutional variation has been wrought by acclimatisation, social environment, and, more than all else, by miscegenation. The influence of miscegenation and the advent of personal liberty are responsible for a new era of diseases. The newer diseases in the negro, of which tabes is an example, are fast becoming more commonly recognised. Tabes, it would appear, exists in the negro more commonly than has been supposed, and failure to recognise it may be due to the abeyance or total absence of the ataxic symptoms in the amaurotic type. Aryan admixture is said to be essential to the production of tabes in the negro.

The Causation of Tuberculosis in Children.

The channels of infection whereby the tubercle bacillus may obtain admission and find a lodgment within the human body are so numerous that in cases of death from infantile tuberculosis it is often a very difficult matter to state with certainty where the original trouble began or how the bacilli gained an entrance into the system. There are those who would contend that the disease, as it affects young children, is nearly always produced by the consumption of specifically infected food, usually milk, while others equally insist upon the importance of contaminated air and bad hygienic surroundings as being the main factors which give rise to the malady. Dr. Cecil Price-Jones (a) has conducted an inquiry into the causation of tuberculosis in children with a view to ascertaining to what extent the disease may be looked upon as being of alimentary origin. From post-mortem evidence it would appear that primary tuberculosis of the bronchial glands which is so frequently observed, especially in children who have lived in large cities, is of respiratory rather than of alimentary origin. The filtering action of the lymphatic glands

(a) British Journal of Nursing, October 10th, 1908.

(a) The Practitioner, August, 1908
affords considerable protection to the organism against tuberculous infection, as the occurrence of intestinal infection apart from lymphatic involvement is regarded as an exceedingly rare if not an impossible event. The main points which Dr. Price-Jones brings forward for consideration are that the probability of the infection of infants with the bacillus of human rather than bovine tuberculosis is rendered more than likely when the nature of their food and the manner of administration is taken into account, and that mouth-breathing of impure air, which practice is so common among the children of the poorer classes, may be a more important source of the disease than milk-feeding.

The Ethics of Locum Tenency.

A curious action was tried at the Watford County Court last week in which a medical man claimed damages from his locum tenens for neglect of duties, in that he had violated medical etiquette by smoking in the streets while visiting, by refusing to see patients after eight o'clock in the evening, and by remissness in attending confinements. Obviously, the question of smoking must be left to the discretion of the locum or else restrictive conditions must be imposed and assented to at the time of engagement; but it is otherwise in the matter of refusing to respond to calls, however untimely, and we are rather pleased than otherwise to find that the unfaithful locum was fined 4s with costs. No special code of ethics is applicable to locum tenentes, since every conscientious man would do for his principal at least as much as he would do on his own behalf. In men of loose moral fibre the ephemeral nature of the engagement induces a regrettable spirit of carelessness and indifference against which the holiday-seeking practitioner cannot be too much on his guard.

The Wiesbaden Eye Hospital.

The appeal published in the lay Press signed by Professor Pagenstecker for funds in aid of the construction of an eye hospital at Wiesbaden is characterised by a certain assurance, and can hardly be expected to attain the object in view. Surely Germany can provide any funds for any requirements of the kind without soliciting alms from foreign countries. The number of indigent English, who receive attention there must be infinitesimal, and numerous German patients are treated every year in our English hospitals without attention being specially called thereto.

A Coroner on the Medical Induction of the Morphine Habit.

At an inquest held on a professor of languages of Shepherd's Bush, who had died from collapse subsequent on the morphia habit, the coroner animadverted on the alleged recklessness with which some medical men systematically resort to injections of morphine without due regard to the risks attending the formation of a morphia habit. We venture to question the competency of the coroner to decide in such a matter, although we fully endorse the general tenour of his observations.

There are painful morbid states in which relief can only be obtained by the routine injection of morphia, and failing the possibility of cure it would be cruel to withhold this one means of affording relief. Only under very exceptional circumstances, however, is it justifiable to instruct the sufferer to make the injection himself, all medical control being thus withdrawn. As a rule, whatever may be stated to the contrary, this form of intemperance is usually indulged in on the patient's own responsibility without any medical authority.

Mr. Brodrick and the Army Medical Department.

At the dinner of the Royal Army Medical Corps last week, Mr. Brodrick discussed the shortcomings of the department during the late war, throwing the blame for its shortcomings on the niggardly policy which had stunted its growth and prevented its adequate development. He regretted the former total absence of stimulus to individual improvement and the general indifference displayed in respect of the organisation of the medical department of the Army, but he was enabled to point to the vastly increased number of candidates for commissions as conclusive that at last the deficiencies had been made good, thanks largely to the advice and assistance of civilians. Parliament has at last been made to understand that if an elastic, competent Army Medical Staff is desired it has to be paid for, a truth it has taken many years to push home.

The Zymotic Death-Rate.

When shall we see the last of this bugbear? With all the hardihood of the evergreen it withstands all the blasts of criticism and all the showers of abuse that beat on its devoted head, and it still stands to the world as the measure of the health of the district. Of course it is nothing of the kind. A rate that includes seven elements gives no information of any practical value, and if it is to survive in the reports of the medical officers of health we should at least like to put it side by side with the death-rate of each of its components, as now appears in the Registrar-General's quarterly and annual summaries. Besides, the death-rate is not of nearly such importance as the incidence-rate in judging of the prevalence of the zymotics; and any rate which is to measure the health of a district and does not include tuberculous diseases is a Hamlet without the Prince of Denmark. Unfortunately, the zymotic death-rate has got a firm hold and a long record, and it will need a good many kicks from a good many quarters before it is consigned to the oblivion out of which it should never have emerged.

In reply to a letter addressed to him by Dr. Milroy, of Kilwinning, Ayrshire, the Home Secretary points out that all necessary information concerning miner's anaemia may be obtained from the report drawn up by Dr. Haldane on the outbreak in Cornwall.

The new East Wing of the Mount Vernon
Hospital for Consumption, at Hampstead, was opened on Tuesday, October 27th, by the Marquis of Zetland, President of the Hospital, and now accommodation is provided for 100 cases of pulmonary tuberculosis.

Dr. V. Lowenthal, in a study of the health of European armies, shows that the German Army is the most healthy, then comes the Italian, and next the British, that of France having the greatest mortality rate. The incidence of venereal disease among British troops is very high.

A circular letter has been sent by the British Medical Association to the editors of the principal London newspapers requesting that in future the names of medical men in attendance on persons other than members of the Royal Family may not be inserted in paragraphs relating to illness.

PERSONAL.

Sir Charles B. Ball, F.R.C.S., has been appointed. Honorary Consulting Surgeon to Monkstown Hospital.

Dr. John F. McLachlan has been appointed casualty surgeon for the northern district, Glasgow, vice Dr. Dickson, resigned.

Sir Arthur Macan, M.B., has been elected King's Professor of Midwifery in the School of Physic, Trinity College, for a third period of seven years.

The Royal Scottish Society of Arts have awarded a Keith prize to Dr. Dawson F. D. Turner, for his work on Röntgen apparatus and other electrical appliances.

Professor Alexander Rollet, of Graz, who is chiefly known amongst physiologists for his work on blood and muscles, has recently died in his seventieth year.

An interesting portrait of Dr. Cowling-Middleton, of Liverpool, the work of Mr. Oswald Birley, is on view in the Continental Gallery Exhibition at Grafton Galleries, London.

H.R.H. The Princess of Wales has graciously consented to become patron of the British Lying-in Hospital (founded 1749), the oldest hospital of its kind in London.

Mr. Clive Riviere, M.D. (Lond.), M.R.C.P. (Lond.), has been appointed a physician to the out-patients at the City of London Hospital for Diseases of the Chest Victoria Park.

Sir J. W. Moore, M.D., has been elected representative of the Royal College of Physicians of Ireland on the General Medical Council in succession to Dr. Lombe Atthill, who has resigned that office.

Her Majesty the Queen has forwarded to the Lord Mayor a sum of £1,000 to start the appeal which is shortly to be made for funds for the enlargement and improvement of St. Bartholomew’s Hospital.

Dr. Masson, of St. Helens, was the victim of a nasty carriage accident last week, his horse having bolted and come into collision with a gas lamp. Dr. Masson sustained a fracture of the leg and severe bruising.

Dr. Sydney Young, D.Sc., F.R.S., Professor of Chemistry, University College, Bristol, has been elected to the Chair of Chemistry in the School of Physic, Trinity College, Dublin, vacant by the resignation of Professor Emerson Reynolds. Dr. Young was elected a Fellow of the Royal Society in 1893, and is the author of numerous publications on scientific subjects.

Special Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

From our Special Correspondent.

BELFAST.

Opening of the Winter Session at the Belfast Medical School.—The first session of the Belfast Medical School in the new Royal Victoria Hospital was inaugurated on Tuesday, October 29th, by an address to the students by the Chairman (and senior member) of the medical staff, Dr. J. Dalton Browne. Dr. Browne began by referring to the altered circumstances in which they met, being at last in a hospital worthy of the commercial capital of Ireland. Naturally their minds reverted to the old hospital which they had just left, and in whose history he personally took a deep interest. From various sources he had culled some facts regarding the history of the school, which he thought might be interesting at the present time. The first mention of a hospital in Belfast was in connection with an epidemic, probably of small-pox, which raged in the North of Ireland in 1641. We are told that thousands of the stricken were crowded into the "Great Hospital of Belfast," though where that hospital was situated he did not know. In 1771 the poor-house and infirmary at the top of Donegall Street was built, and began to give medical relief to the poor in 1774. About 1798 typhus fever became very prevalent, and at a public meeting it was decided to open a fever hospital, but it was on a very small scale, as only six beds and one man were provided. Charity languished or flourished, according as the town was healthy or fever-stricken, till 1810, when the need of accommodation for cases of accident and disease of various sorts led to the planning of the old Royal Hospital, the foundation-stone of which was laid in 1815. This was the hospital they had just left. A severe epidemic of typhus in the years 1816 and 1817 hurried on the building, and patients were transferred from the Old Fever Hospital to it in 1817. In the year 1820, the committee permitted each member of the staff to have one pupil to witness the practice, and in 1836 clinical teaching was formally recognised as part of the duties of members of the staff. In 1835 a medical department was inaugurated in the Belfast Royal Academic Institution, after long conferences between the managers of that school and the committee of the hospital. Chairs of anatomy, theory of medicine, surgery, chemistry, materia medica and pharmacy, midwifery, and botany were founded. The first professor of anatomy was Dr. J. L. Drummond, a most devoted teacher, and adopted by his pupils, to whom he lectured at any hour of the day or night that suited their convenience. The first professor of chemistry was the illustrious and world-renowned Andrews, to whose teaching many of his colleagues had listened in later years in Queen’s College. The original chair of surgery was occupied by his old friend and teacher, Alexander Gordon, more familiarly known as "Alick." Who could forget him, the careful observer, and the force with which he drove into the minds of his students the principles of surgery? In the chair of medicine was Henry Mac Cormac, father of the late Sir Wm. Mac Cormac. He lived half a century before his day, being the pioneer of the fresh-air treatment of tuberculosis years before Koch was born or Nordrach heard of. He contended that consumption was due to breathing pre-breathed air, and advocated free ventilation in all rooms day and night. When called to see a patient in an ill-ventilated room, he invariably ran his stick through two or three panes of the window before prescribing. The various professors continued at work till 1840, when the school in the Royal Academic Institution was replaced by the medical faculty of Queen’s College. In 1875 the General Hospital became by Royal Charter the Belfast Royal Hospital, and in 1899, by a further charter, the Royal Victoria Hospital, a name which points to the building in which they met for the first time that day. In
1873 he (Dr. Browne) joined the staff, which then consisted of four physicians and four surgeons. Special duties for pathology and gynaecology were added in 1882; subsequently a dentist and a pathologist and various assistants were added; and now the staff numbered seventeen. At various times the accommodation had been increased by the addition of new wings to the hospital, the last increase, in 1893, raising the total number of beds to 150. Meantime, the medical school flourished, and in 1876 occupied the proud position of the third largest medical school in the United Kingdom. In 1896 Sir Wm. Whitley, the late Professor Cuming moited the question of increased accommodation, and the Lord Mayor of Belfast called a town meeting, at which the scheme of building a new hospital in keeping with the increasing needs of the city was enthusiastically taken up. The outcome they all knew. Dr. Browne then proceeded to give the students some advice as to the manner in which they should pursue their studies, and also in relation to their careers after they had obtained their degrees. He referred to the many inducements now offered to young medical men in the army and navy, and then said he must bring the present unsatisfactory conditions of the Irish Poor-law Medical Service under their notice. They had only to read the papers to see how the members of the profession were being treated by those responsible for the oversight of the service. They must not permit him to go fully into the matter, but he must strongly impress on them the desirability of leaving those appointments severely alone until the present grievances were redressed and the conditions of service made such that an educated and respecting medical man could enter it with advantage. Dr. Browne then pointed out the great facilities the students of the Belfast school now enjoy for the study of the special branches of their profession. In conclusion, he warned them of the mistake they would make if they took up the profession of medicine in the hope of making a fortune; but if they were ready for work they might rely on a decent competence, and their life would be a happy one, their social position would be a good one, they would be the trusted friend and confidential adviser of many of their patients, and their name would be honoured in the land in which they dwelt.

Correspondence.

SPECIALISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—The lecture to which reference is made to-day, on editorial and correspondent columns was, it must be remembered, addressed to post-graduates, qualified men with some knowledge of their professional world; hence, no doubt, it was not thought necessary by Sir W. S. Church to offer more than the word. In an audience for whom a hint ought to suffice. If your correspondent, "Non-Specialist," were a specialist he would probably have had a view of the seamy side of specialism—a view which unfortunately is by no means always brought clearly within the visual range of the average practitioner. Lest I should be misunderstood, let me preface my observations with a personal declarative that I am unable to claim membership of that higher profession is to me the highest honour. The profession stands second to none; beyond any other it is composed of men leading lives of true self-sacrifice and devotion to duty. It is with this feeling and with full sense of the responsibility I am in making the following statement that I venture to affirm that there exists in London a considerable number of specialists who show by their methods that their object is not to obtain fair recompense for honest services, that they value all things not to do the best for the patient, but that their paramount consideration is the making of money regardless of the injury inflicted upon the victims who place themselves with confidence in their hands. Those quacks, outside the profession—practice by unqualified pretenders—does no harm from any point of view to the legitimate practitioner is, I believe, capable of proof. It is quackery within which does harm. Of those who fall into the hands of qualified quacks a large proportion never recognise that they have been victimised, but many do; and these and their friends are too often had to look with suspicion upon the whole body of medical men, if they do not regard them as, at least, worse than useless, on a level with each other whom they have been misled, and who they have been led to believe were eminent members of the profession.

I am, Sir, yours truly,

A SPECIALIST.

October 21st, 1903.

Obituary.

MR. JAMES TREYAN, M.R.C.S.

We regret to announce the death of this gentleman, which took place after a short illness at his residence, 9, Northumberland Road, Dublin. The deceased gentleman was one of the first students of University College, London, and as far back as 1875 he took the M.R.C.S. Eng. He practised medicine in Baltimore, and on retiring from practice went to live in Dublin. Up to the last he took an interest in medical practice. He leaves a son, Dr. F. J. Teevan, medical officer of Rawboy workhouse, and consulting medical officer of health to the union.

JAMES ROBERT WALLACE, M.D., F.R.C.S. E.

The death is announced as having occurred at Calcutta on September 27th of Dr. James Rob. Wallace, a prominent Georgian and president of the Imperial Anglo-Indian Association. He was born in 1876, his father being a private in the Army, and educated at a military orphanage. He started life in the subordinate medical service, but being possessed of talent and acumen he found means to study medicine and finished by taking the degrees of M.D. and F.R.C.S. at Edinburgh. Thereupon he started practice in Calcutta, and soon attained a good reputation. Dr. Wallace also founded and edited the Indian Lancet. He was, however, best known for his advocacy of the cause of the community of which he was the acknowledged leader. Dr. Wallace came to London on several occasions, and endeavoured to persuade the military authorities to allow the admission of Eurasians to the Army under schemes he was putting forward. He was also the author of a proposal for the establishment of a training-ship for Anglo-Indian boys on the river Hooghly, in reference to which the Admiralty Board met in correspondence with the Government of India.

MR. CHARLES STURGES-JONES, M.R.C.S., L.R.C.P.

The death of Mr. Charles Sturges-Jones occurred at his residence in West Street, Chichester, on Wednesday of last week. Born in 1822, the deceased was almost eighty-one years of age, and no fewer than five years of his life were spent in the cathedral city. He was the son of the late Rev. Edward Jones, Rector of Milton Keynes, Buckinghamshire. Educated at Christ's Hospital, Mr. Sturges-Jones qualified as a surgeon's Apprentice in 1847, and for ten years he represented the West Ward on the City Council, but retired in 1885. He was a generous supporter of practically all local institutions. Although he had been ailing more or less since the summer, it was not until a week ago that he was compelled to take to his bed, and the end came peacefully from no other cause than that of old age.
Medical News.

A Free Course of Post Graduate Lectures.

We are asked to announce that the course of weekly lectures now being delivered at the Mount Vernon Hospital for Consumption, Hampstead, by members of the staff, is open without fee to members of the profession and to medical students on presentation of their address cards. The next lecture of the course will be delivered to-morrow (Thursday) at 5 p.m. by Dr. J. E. Squire, on "The Diagnosis of Early Tuberculosis by demonstration of Sputum." The remaining lectures will be delivered on succeeding Thursdays by Drs. Geo. Johnston, F. Parkes Weber, T. N. Kelyanck, and J. T. Lister, and Messrs. Jas. Berry and Richard Luke.

Medical Service at St. Paul's.

The annual medical service at St. Paul's Cathedral, in connection with the Guild of St. Luke, was held on St. Luke's Day, and was attended by about 1,000 medical men. Those wearing their robes, numbering between 200 and 300, assembled near the west door, and walked in procession up the nave to reserved seats under the dome. Among them were the provost of the guild, George C. Well (Dr. Russell Wells), the vicar, Sir Dyce Duckworth, Dr. Symonds Thompson, Dr. Sanson, Dr. Caley, Dr. Sedgwick, Mrs. Scharlieb, Surgeon-General Codrington, Surgeon- Colonel Welch, &c. The master (Dr. W. Parson) and the chapel's Organist occupied seats in the choir. The musical portion of the service was rendered by members of the London Church Choir Association, under the direction of Dr. H. Waldorf Davies (hon. conductor to the association). An opening voluntary was played by Dr. Graham (musical Fellow of the College of Physicians), Mr. Kiddel afterwards presiding at the organ. The prayers were read by Minor Canon Morgan-Brown, and the lessons by the Rev. W. H. H. Jervois. The sermon was preached by Prebendary Villiers (vicar of St. Paul's, Knightsbridge) from the words, "But there is a spirit in man; and the inspiration of the Almighty giveth them understanding." (Job xxxii., 8). Before the conclusion of the service a collection was taken on behalf of the Medical Mission Fund of the guild.

Harvest Society of London.

The harvest lectures of the Society will be delivered this year on November 5th, 12th and 19th, by Dr. D. B. Lees, at the Stafford Rooms, Titchborne Street, Edgware Road. The subject selected by Dr. Lees for his lectures is "The Treatment of Some Acute Visceral Inflammations."

Royal College of Physicians of Ireland—Annual Meeting.

At the stated annual meeting of the Royal College of Physicians of Ireland, held on the morning of St. Luke's Day, the following officers were elected for the ensuing year:

EXAMINERS FOR THE CONJOINT DIPLOMATES IN PUBLIC HEALTH:

Hygiene, Henry T. Bewley, M.D.; Chemistry, Prof. E. Lapper; Meteorology, Sir John W. Moore. Extern Examiners in Preliminary Education: Prof. W. E. Thrift, F.T.C.D.; Mr. W. Kennedy, F.T.C.D. Representative on the General Medical Council: Sir John W. Moore, M.D. Representatives on the Committee of Management: J. Magee Finny, M.D.; Walter G. Smith, M.D., and James Craig, M.D. Treasurer: Henry T. Bewley, M.D.; Registrar: James Craig, M.D. The Registrar reported the death of Dr. Duffey, an ex-President of the College, and the following resolution was adopted in silence:

"Resolved: That on this, the first meeting of the College since the death of Sir George F. Duffey, we, the President and Fellows, desire to place on record our deep regret at the loss the College has sustained by the removal of one of its Fellows and past-Presidents, who was ever loyal to the College, and upheld the highest principles of our profession. Regular in his attendance, painstaking and helpful at Committees, he has left a place it will be hard to fill, while personally we feel we have lost a genial conferee and a generous friend. We desire that a copy of this resolution be forwarded to Lady Duffey with the unanimous expression of our sincere sympathy with her and her family in their bereavement."

Dr. Atthill, having tendered his resignation of the office of Representative on the General Medical Council, the following resolution was adopted unanimously at a previous meeting of the College:

"Resolved: That the President and Fellows accept the resignation of their Representative on the General Medical Council with sincere regret, and take this opportunity of expressing their grateful sense of the invaluable services rendered to the College by Dr. Atthill through a long series of years, not only in the capacity of representative on the General Medical Council, but also in many other important collegiate offices."

The annual dinner of the College was held the same evening and was largely attended.

Annual Dinner of the Staff of St. Vincent's Hospital.

The annual dinner of the staff of this hospital was held on the 21st inst. at the Shelburne Hotel. Surgeon Tobin occupied the chair, and many guests were present. After dinner, several speeches were made and toasts were drunk. Mr. M'Ardele, surgeon to the hospital, in the course of a speech, said that the question had been asked as to whether the Government were to set up the Poor-law Medical Service in a Civil Service. He was of opinion that the answer to that question was the simple word "No." He doubted that Mr. M'Ardele's answer will commend itself either to the members of the Poor-law Medical Service or to those members of the general public who are in present conditions under which that Service is worked and vacancies are filled.

PASS LISTS.

Royal College of Surgeons, Edinburgh.

At a meeting of the college, held on the 21st inst., the following gentlemen having passed the necessary examinations, were admitted Fellows of the College:

Notices to Correspondents, Short Letters, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a detached sheet of paper (ficial), and avoid the practice of signing themselves "Reader," "Subscriber," or "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side only of the paper, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Extracts from the Medical Press appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications if possible to Dr. Blandy, Colone, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Mr. Stanley Baxley's interesting case is marked for early insertion.

HOSPITAL SHOPPING DAY.

R.M.O.—Members and Fellows of the Royal College of Physicians sign complaints, &c., and although, as has already been stated in the preparation of this undertaking concerns only the college and its constituent members individually, it is highly probable that the course would direct a non-medical reader to our recollection that this course has been followed. No such restriction applies to the Fellows of the College of Surgeons.

Mr. Alex. Buxton. —You are quite entitled to withhold your signature from the letter, as you believe a portion of it is "intended for the payment of vivisectors' salaries, or the purchase of animals for vivisection": the hospital authorities will we hope announce to you the use that such a letter, if it were written, would be made. You are, however, not justified in striving to induce others to withdraw their support on the strength of your ridiculous assertions. Your request for insertion of your letter in our columns, is indicative of the character of the writer.

Mr. C. O. K. —We thank you for your suggestion, which, however, we are at present unable to carry into effect. K. Y. S. —The Annual Meeting of the St. Luke's Hospital, Liverpool, to be held on Thursday, September 6th, is at present in course of preparation. Dr. H. R. (Philadelphia).—As far as possible references to quotations are given in the text, as g-to-g. There are, however, limits to this, if only in regard to space; moreover, unless the quotation be embodying an original idea, such reference is unnecessary and consistent with the particular instance which you mention the title was the only part of the article reproduced.

Meetings of the Societies, Lectures, &c.

HUNTRILL SOCIETY (London Institution, Finsbury Circus, E.C.)—8.30 p.m. Clinical evening, Tuesday, October 2nd.

MEDICO-PHYSIOLOGICAL SOCIETY (South-Eastern Division) (St. Luke's Hospital, E.C.)—3 p.m. Tuesday, October 2nd. Meeting at St. Luke's Hospital. Discussion on the Relation of Hysteria to Insanity (opened by Dr. Edridge Green).

ROYAL UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.)—8 p.m. Card Specimens will be shown by Mr. G. H. Goodenough, M.R.C.S., and Mr. W. C. Doherty, M.R.C.S., at 8.30 p.m. President.—Mr. E. E. Kittel.—Tumour of Choroid in an Eye with Old Chorioditis.—Mr. J. H. Fisher.—Case of Tumour of the Choroid associated with Iritis.—Major F. O'Kliney—An Anomalous Case of Tobacco Amblyopia.—Mr. H. M. More—The Pathological Anatomy of the Flapwe in Epiphora-keratitis.

CHILDHOOD SOCIETY (Library of the Sanitary Institute, 73 Margaret Street, W.)—8 p.m. Lecture.—Mr. A. W. Newton—Psychology and Education.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.)—5 p.m. Dr. J. Edward Squyre.—The Diagnosis of Early Tuberculosis of the Lung.

HOSPITAL FOR DISEASES OF THE THROAT (Golden Square, W.)—4.30 p.m. Dr. Tiley—Diseases of the Nose.

BRITISH HISTOLOGICAL AND CLIMATOLOGICAL SOCIETY (30 Hanover Square, W.)—6.30 p.m. General Meeting.—Address: The President (Dr. Ltd.—Address of Cases in Seaside Climatology.

HOSPITAL FOR DISEASES OF THE THROAT (Golden Square, W.)—4.30 p.m. Dr. Lask—Diseases of the Larynx.

Appointments.

DEATHS.

ENNE, T. WATTS, M.D.Edin., Physician to the In-patients at the Oasis Hospital for Women.

HARR, R. G. D.M.Ont., Lecturer in Pathology at the Wellington Hospital Medical School.

HAYLE, J. E., M.B., M.R.C.S.Edin., Clinical Assistant to the Obstetrician for Women.

HEEFE, W., D.C., F.R.C.S., D.C., D.C., D.C., Assistants Medical Officer to the Walton Workhouse, Liverpool.

HICKS, J., H., M.D., Medical Officer of Health of Cromer.

HICKS, J., CH. W., M.D., Clinical Assistant to the Obstetrician for Women, Manchester Children's Hospital, Festubury.

HOLTER, J. F. W., M.B., B.S., R.C.I., Medical Officer of the Oude District of Schill, January.

HOGG, F. W., M.R.C.S.Lond., L.R.C.P.I., Certifying Surgeon under the Factory Act for the Greenwich District of the county of Kent.

HICKS, C. M., M.D., L.R.C.P.I., Certifying Surgeon under the Factory Act for the Bethesda District of the county of Kent.

HICKS, W., F., M.B., B.S., R.C.I., M.R.C.S.I., Medical Officer of the Holloway and North Islington Dispensary.

HICKS, F. C. M., R.C.I., Lecturer in Biology for Westminster Hospital Medical School.

Vacancies.

Birkenshead Union.—Resident Assistant Medical Officer. Salary £2 per annum, with board, washing, and £5 per annum to John Carter, Clerk to the Guardians, 45 Hamilton Square, Birkenhead.

County Borough of Sunderland.—Port of Sunderland.—Medical Officer of Health. Salary £250 per annum as Medical Officer of the Borough and £20 per annum for the Port. Applications to Miss M. Bowes, Town Clerk, Victoria Hall, Sunderland.

Dartington Hospital and Dispensary.—Salary £25 per annum, with board and lodging in the establishment. Applications to the medical officer of the hospital.

Graveley Hospital.—House Surgeon. Salary £120 per annum, as board and residence. Applications to F. H. Stevens, Esq., Assistant Medical Officer, 64 Milton Square, Graveley.

Hackney Union.—Second Assistant Medical Officer. Salary £25 per annum, together with rates furnished apartments, washing and attendance. Applications to Frank B. Cole, Clerk to the Guardians, Clerk's Office, Hackney Union, Hoxton, N.E.

Leeds General Infirmary.—Resident Ophthalmic Officer. Salary £20 per annum, with board, lodging, and washing. Applications to Secretary to the Faculty, General Infirmary, Leeds.

North Cambie Hospital, Wishack.—Resident Medical Officer. Salary £120 per annum, as board and residence. Applications to F. J. Gardner, Hon. Sec, Wishack.

North-Eastern Hospital for Children, Hesketh Road, N.E.—Resident Physician Salary £20 per annum, with board, residence, and laundry allowance. Applications to the Secretary.

North-Eastern Hospital for Children.—Resident Medical Officer. Salary £150 per annum, with board, residence, and washing. Applications to J. J. Bannister, Esq., Southfield, Hesperch.

Rockdale Infirmary.—Resident Medical Officer. Salary £200 per annum, with board, residence, and washing. Applications to Sec., R. H. Shaw, Esq., Southfield, Rockdale.

Royal London Ophthalmic Hospital (Shoreditch Eye Hospital), Old Road.—Senior House Surgeon. Salary £100 per annum, to be paid in six months. Applications to Secretary, Old Road.

Suffolk County Hospital, Ipswich.—Medical Officer. Salary £10 per annum, with board, lodging, and washing. Applications to E. Forster, House Governor and Secretary.

Births.

LAMY.—On Oct. 2nd, at Blaise House, Littlehampton, the wife of Cecili E. Lestrade, M.B.C., L.R.C.P.Lond., of a son, stillborn.

OTHAMERT.—On Oct. 5th, at Indore, Central India, Ali (see Froyon), the wife of Capt. Austin E. Othamert, R.A.M.C., of a son.

PULLENS.—On Oct. 2nd, at 20 Kemplay Road, Hampstead, N., the wife of Herbert Pulleis, M.A., M.B., B.C.Ont., of a daughter.

THOMSON.—On Oct. 2nd, at 17 Euston Road, E., the wife of William Thomson, M.B., of Ashley Road, E., of a daughter.

Marriages.

RAPER—BEE.—On Oct. 20th, at All Saints Church, Marset Street, W., William John Raper, L.R.C.P., M.ES.C., Mr. Alkington, only son of William Raper, of 22 Robert Avenue, Plymouth, to Beatrice Letitia May, widow of G. B. Bee, Esq., District Officer, Kenia, East African Protectorate, daughter of the late J. G. Bee, of the Hôtel de France, Boulogne-sur-Thanne.

Deaths.

SMITH.—On Oct. 22nd, at Blackheath, in her 70th year, Amelia, the daughter of James Pearson Smith, M.D., of Great Yarmouth.
Paris Clinical Lectures.

APPENDICULAR TOXIC NEPHRITIS; APPENDICULAR ALBUMINURIA.

By Professor Dieulafoy,
Physician to the Hotel Dieu, Paris.

Our knowledge of toxic appendicular nephritis is still far from complete, but reduced to its simplest expression it manifests itself by one constant sign: albuminuria. It is rare for the kidneys to escape damage in a severe attack of appendicitis, and since my attention was called to this manifestation of appendicular toxemia I have discovered the existence of albumin in the urine of a large number of such patients.

Albuminuria may set in during the first three days, and it is sometimes associated with the yellow discoloration of the skin which is a characteristic symptom of appendicular toxemia. Sometimes the urine only contains a trace of albumin, but at others we may find as much as from five to one gramme per litre. On several occasions I have been enabled to note the gradual decrease and the ultimate disappearance of the albumin after removal of the appendix. Of this complication I am able to mention several instances.

On August 14th, 1903, I was called to a case of appendicitis at the Hôtel Dieu. The patient had been treated three weeks in a medical ward before he came under my care. It was one of those too numerous cases which are left to Nature, and Nature, we know, when left to herself at such times, even when assisted by ice and opium, often leads to disaster. In this case, for instance, after an amelioration of the symptoms, the temperature suddenly rose; vomiting set in and the outlook became very grave. After examining the patient I came to the conclusion that there was peritonitis of appendicular origin, which had spread to the subphrenic region (this was afterwards confirmed at the operation). The urine examined at this time contained rather more than one gramme of albumin per litre, but there were no casts. The appendix was removed and from that time the albumin diminished. On August 24th there were 30 centigrammes per litre; on the 26th, 35 centigrammes; on the 28th, from 15 to 20 centigrammes; and in September it had entirely disappeared, the patient being in a satisfactory condition as regards convalescence.

Some time ago I published notes of a case of gangrenous appendicitis, accompanied by albuminuria and jaundiced skin (toxic appendicitis). The patient was operated upon, and although the improvement was somewhat delayed, in a few days the albumin, pigments and jaundice diminished and disappeared.

Simple albuminuria, by which we understand albuminuria unaccompanied by casts and disappearing when the appendicular lesion has been dealt with, is the only obvious urinary symptom in slight attacks of appendicular nephritis. In a case like this the renal lesion is only transient, but nevertheless we must not attach too much importance to its apparent benignity, because this simple albuminuria, with or without jaundice, is occasionally the premonitor of serious complications which may prove fatal. To avoid repetition I will relate a few observations to which I have already referred in detail in a previous lecture.

On June 2nd, 1901, a boy was admitted into hospital suffering from toxic appendicitis of four days' duration. The liver and the kidneys were already affected by the toxins, for the urine showed a tolerably large amount of albumin and contained in addition granular casts, leucocytes and biliary pigments. The operation was performed late; the vomiting became intense and the matter vomited was of a dark colour (vomito negra appendicular), and the patient ultimately succumbed from toxæmia.

At the post-mortem examination, the kidneys appeared to be normal, and showed no increase in size or weight. If we had contented ourselves with a superficial examination only, we should certainly have considered them to be healthy. On microscopic examination, however, the epithelium of the convoluted tubes showed two different kinds of lesions—in the one the changes were similar to those seen in coagulation necrosis, in the other the alteration was characterised by the granular appearance of the protoplasm of the epithelial cells. These changes indicated recent degenerative hyperacute nephritis, the cause of which is probably the elimination of a toxin by the kidneys.

At the autopsy of another case, also operated upon too late with a fatal result, the kidneys to all appearances were normal; on section, however, the cortex seemed somewhat discoloured, but the histological examination, made a few hours after death, showed the changes associated with degenerative hyperacute nephritis. The epithelial lesions (necrosis and hyperacute degeneration) were localised in the convoluted tubes and in the large branches of Henle's tubes, which constitute the secretory apparatus of the kidneys. The liver cells showed signs of fatty degeneration.
Lorain recently published notes of a similar case. At the post-mortem examination the kidneys looked healthy, but when they were microscoped there was coagulation necrosis affecting the secretory epithelium. There was also in the case degeneration of the hepatic cells together with the deposit of pigment. Lorain concludes from these lesions, coupled with those of the other organs, that death was due to the poisonous intoxication of the organisms rather than to mere infection.

Let us now consider these cases of acute toxic appendicular nephritis from an anatomical and clinical standpoint. From an anatomical point of view the kidneys are usually not obviously affected. They are not larger than normal, nor are they of a paler colour; in fact, they do not at all resemble the large white kidney. But microscopically the lesions are well marked and affect the essential anatomical elements of the organisation; in severe cases the death of the cell is brought about rapidly by the toxin generated by the appendicular lesion, and the liver cells participate in the process.

From a clinical point of view the symptoms of appendicular nephritis do not resemble those of acute nephritis. This variety of nephritis is not comparable with either scarlatinial nephritis or syphilitic nephritis, or with nephritis brought on by a chill. The well-known symptoms of acute nephritis, such as swelling of the face and eyelids, oedema, anasarca, oedema of the lungs and exudations from serous membranes, are not met with in appendicular nephritis, or at all events I have never observed them.

This nephritis often escapes observation, owing to the absence of obvious symptoms and the absence of that very important sign, the swelling of the face and eyelids. We ought, therefore, to examine the urine of every patient suffering from appendicitis as a matter of routine. Albuminuria, which, in other varieties of acute nephritis, is considerable may be of moderate severity in appendicular nephritis. If, therefore, granular casts are discovered in the urine on the second or third days, the prognosis is thereby correspondingly aggravated. Albuminuria in appendicitis does not always justify us in giving an unfavourable prognosis, but it is nevertheless one of the signs of impending toxæmia, and should be regarded as a warning of danger. This danger does not depend only upon the nephritis (which in some cases may lead to anuria, with or without oliguria), but on the general intoxication of the organism, in fact, it is the result of appendicitis.

The yellowish discoloration of the skin, the other sign of appendicular intoxication, is often associated with albuminuria; these two signs are frequently early and contemporaneous. They are not necessarily of bad augury, but still it is impossible for us to ascertain beforehand whether the liver intoxication will cause only a slight nephritis or nephritis, or whether it may lead to complications of a more widespread and graver character, such as toxic gastritis, facial vomiting, renal and hepatic inadequacy, to nervous symptoms and to general toxæmia, and finally death.

What, then, must we rely upon to guide us in our prognosis? Practically there is next to nothing; the temperature does not assist us. We have seen cases in which death was obviously impending, although the temperature was normal. In the first case, mentioned above, the temperature oscillated between 37° and 38° C. In Mr. Lorain's patient the temperature remained at 37° C. for several days before death. Even the pulse itself is not very trustworthy from a prognostic point of view.

The course of an attack of appendicitis is treacherous, and the poison often does its lethal work without revealing its existence. We have gone beyond the old classical descriptions which represented appendicitis as a local affection, that is to say, that most dangerous complication whereof was peritonitis, and the anatomical pathological classification which was relied upon in formulating the prognosis has quite fallen into abeyance.

The facts which I have mentioned teach their own lesson. They show what toxic appendicular nephritis is, they take us through the whole series of toxic complications, showing with what rapidity these toxins act, and constituting another argument, if such were needed, in favour of early surgical intervention. They serve to bring into relief the dangers of temporising and bringing into disrepute the doctrine that operative interference should be resorted to only when the attack has subsided.

The day will come when the advocates of the expectant attitude will have to give us arguments more convincing than mere speculating. We offer them precise and irrefutable proofs: let them do the same on behalf of their views. We know the cause of death in many of these cases where the attack of appendicitis has been allowed to run its course, and we can prove that it was brought about by toxæmia. Why was the patient not operated upon before he became intoxicated and infected? We ask for an answer based on facts!

Before concluding this lecture I wish to call attention to the similarity which the appendicular liver presents with the appendicular kidney. In the appendicular liver I have described two stages: an early toxic hepatitis which does not suppurate and a later infectious hepatitis which occupies an important place in the history of the appendicular liver; the purulent infectious hepatitis can be easily explained by the transmission of the infective agents from the appendix to the liver by means of the appendicular veins and the portal vein. This does not apply to the appendicular kidney, for in this case the infective agents would have to travel in a very circuitous way to reach it. This explains the comparative infrequency of infectious nephritis with renal abscess; whilst, on the other hand, toxic nephritis in its less severe form is more common.

We have to ask ourselves finally whether this affection of the kidneys by the appendicular toxins does not enter into the etiology of chronic nephritis and of Bright's disease. I think, too, that the liver affection due to the toxins (acute or chronic appendicitis) may be a factor in the etiology of cirrhosis of intestinal origin.

A private conference was lately held at the Bute Arms, Aberdare, for the purpose of drafting a scheme whereby the appointment of doctors shall be made by the miners themselves in lieu of the present system of paying so much per £ out of their earnings. The men employed at the Duffryn Collieries and at the Cwmanion Company's pits have already formulated a scheme, the operation of which is deferred pending the obtaining of the companies' sanction.
Lectures on Primary Malignant Intra-Thoracic Tumours. (a)

By T. N. Kelynack, M.D., M.R.C.P.,
Assistant Physician, Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood, London.

In entering on a study of the evidences of intra-thoracic growths it is most necessary to recognise the immense importance of thorough systematic invasion. In the cases (1) subjective and (2) objective signs precede the appearance of (2) definite local evidences. In some instances, also, manifestations of a more or less general character occur before local evidences are apparent. Not infrequently progress in the evolution of an intra-thoracic growth is so slow and insidious as almost to merit a legitimate use of the term latent, while in other development may be remarkably rapid, and the growth may be so situated as to give rise to pressure effects, or involve important structures, the impairment of function which may give rise to serious symptoms.

In my last lecture I remarked that dependent on the site of the tumour and the manner and direction of its growth we might group the clinical manifestations into those which may be termed evidences of (1) centrifugal and (2) those of centripetal extension.

MANIFESTATIONS OF INTRA-THORACIC TUMOUR.

General Evidences.—Very great differences occur in the general symptoms.

In some cases, particularly where growth is rapid, the whole system may suffer markedly. But in others there may be for some time but little or no apparent involvement of the general health. In some, wasting, rapid loss of weight and conspicuous anaemia occur early, but a distinct cancerous cachexia is not usually pronounced. There may be "clubbing" of the fingers and toes. It is told that "an acute general infiltrating cancer (of the lung) may run a course almost indistinguishable from that of acute pneumonia, commencing with rigors, herpetic eruption, high fever, with rapid consolidation of the lung and albuminuria (Wilson Fox)." Certainly, pyrexia not infrequently occurs in connection with the quickly growing lymphadenomata, and night sweats are not uncommon. Wilson Fox mentions cases which ran "an acute course, marked by fever, sweating, and rapid emaciation, occasionally combined with delirium or coma, and having a deceptive resemblance to tuberculous meningitis." Some of the growths of the lung present clinical evidences somewhat closely resembling phthisis. A sense of weakness is readily developed, and inability for exertion may be an early symptom. Insomnia is often very troublesome.

DERANGEMENT OF RESPIRATORY FUNCTION.

The most conspicuous evidences of disorder are usually best marked in connection with the respiratory apparatus. This is generally so whether the initial seat of the growth be in the mediastinum, or lung, or pleura.

(1) Dyspnoea is generally an early symptom, and may for long be the chief or only trouble. It varies much in type and severity, dependent chiefly on the anatomical situation and pathological characters of the growth. (2) It may be persistent. (3) Not infrequently it is distinctly paroxysmal. And even when the dyspnoea is constant there is commonly marked paroxysmal exacerbation. Attacks of so-called "spasmodic asthma" are often met in connection with mediastinal growth. (4) Sometimes the dyspnoea is distinctly altered by variation in posture. Occasionally the dyspnoea is distinctly of an (a) inspiratory or (b) expiratory type. (4) In some instances the shortness of breath is, however, only perceptible on exertion. But in practically every case of any type effort increases the dyspnoea. (f) Expectoration, involvement of the phrenic nerve may produce derangement in the action of the diaphragm. (g) Orthopnoea develops in a large number of cases as the disease progresses. The attitude in these cases is often very characteristic. (2) Evidences of tracheal or bronchial obstruction are often marked. A wise use of the laryngoscope may be of much service. (3) Cough is a common, and may be a very early, symptom. When the growth is primary in the lung but little cough may occur, but if the bronchus or growth situated in the mediastinum produces irritation of the respiratory passages cough may be a conspicuous and persistent trouble. It varies somewhat in character—being (i.) stridulous; (ii.) spasmodic or paroxysmal; (iii.) clanging; (iv.) dry or irritable.

(4) Hemoptysis, when present, is, of course, an important symptom, but, generally speaking, it cannot be considered common or particularly helpful in diagnosis. Sometimes, however, a large haemorrhage occurs and directs attention to the local cause.

(5) Expectoration.—Examination of the sputa does not usually afford much assistance. The continuation of sanguineous expectoration may sometimes throw suggestive light upon the case.

(6) Alteration of voice is suggestive of mediastinal involvement, and may vary from a slight hoarseness to absolute aphonia. It is only by a careful examination of the case that the precise cause of the vocal deterioration may be rendered apparent. It may be due to:—(a) direct pressure upon the trachea; (b) invasion of its walls or ulceration into its lumen; (c) involvement of the vagus or its inferior laryngeal branch; (d) local conditions in the larynx.

CARDIO-VASCULAR DERANGEMENTS.

The cardio-vascular mechanism may be involved directly or suffer indirectly. The arteries and veins are often extensively involved, and sometimes actually invaded, and the vagus and cardiac plexuses may be compressed. Hence, various manifestations of derangement in cardio-vascular function are common, such as palpitation, increase, slowing, irregularity or asymmetry of pulse (pulsus paradoxus may occur), syncopal or even anginal attacks.

Cyanosis is often a conspicuous feature. The venous obstruction may also be combined with evidences of deficient blood aeration. Not infrequently venous congestion of the face and neck, usually bilateral, and often associated with puffiness of the eyelids, and even more widespread oedema, affords the earliest clinical sign of mediastinal obstruction. The development of lividity and swelling of the head and neck give the patient...
a very characteristic appearance. When such conditions become permanent they are often associated with many troublesome manifestations of cerebral engorgement.

**Alimentary Disturbances.**

**Dysphagia** may be one of the first manifestations of deep-seated mediastinal growth. It is usually considered to be a more frequent and persistent symptom than in aneurysm; the degree of dysphagia, however, may be varied sometimes by alterations in posture. The difficulty in swallowing is aided by accompanied distinct pain and distressing subjective sensations.

**Vomiting of blood** may exceptionally occur, as when the growth ulcerates into the oesophagus.

**Nervous Derangements.**

I have already alluded to the manner in which the growth may surround, compress and even actually invade nerve structures. (a) Involvement of the *sympathetic* may lead to constriction of the pupil, which may be accompanied by ptosis; sometimes, however, the pupil is dilated. Unilateral vaso-motor disturbance is occasionally noticeable. (b) Pressure on the *brachial plexus* may produce sensory disturbances in the arm and exceptional motor and trophic changes. (c) Involvement of the *sphenus* has been thought to be accountable for attacks which sometimes occur. (d) Rarely the *phrenic* is affected. (e) *Spinal* symptoms are sometimes present. The numbness and paraesthesiae occasionally met with in the lower limbs are thought by some to be due to congestion secondary to pressure on the vena azygos. But exceptional growths may actually invade the spinal membranes and compress or even invade the cord itself.

**Physical Examinations.**

As I have repeatedly urged, a sound anatomical and pathological knowledge is essential for accurate observation and correct interpretation of physical signs.

In the investigation of a case of supposed intra-thoracic growth systematic examination is essential.

It is only possible for me now to catalogue, as it were, the more important points to which attention should be directed.

**Inspection.**—(1) First and foremost must be placed the signs of *intra-thoracic venous obstruction.* (2) Occasionally superficial involvement of the thoracic walls by growth may be observed. (3) The lymphatic glands may be involved, and the supra- and infra-clavicular and axillary should always be carefully examined. (4) Alterations in the shape and extent of the chest may occur—(i.) There may be general enlargement. (ii.) Unilateral increase may be a suggestive indication of intra-thoracic growth. (iii.) Unilateral retraction may occur in cancer of the lung, as when a growth involving a main bronchus leads to pulmonary collapse, or where extensive pleuritic adhesions are present. (iv.) In some instances local bulging may be observed. (5) Interference with the respiratory movements often afford valuable information.

**Percussion.**—Careful digital examination often amplifies the information arrived at by thorough inspection. Tactile sensations sometimes afford much trustworthy information concerning intra-thoracic morbid conditions. Special attention must be devoted to areas giving rise to sense of increased resistance, abnormal firmness, al-

*teration in vocal, tussive, and rhonchial fremitus.* It must be remembered also that occasionally distinct pulsation may be detected over an intrathoracic growth so closely simulating aneurysm.

**Percussion.**—Great variation may occur in the signs elicited by percussion. This is due to:—(i.) Seat, size and shape of the growth; (ii.) the secondary changes occurring in the growth; (iii.) associated pulmonary and pleural changes. Hence we find:—(a) Sometimes marked hyperresonance, a tympanitic note, or quite exceptionally a cracked-pot sound. (b) The most characteristic feature is, of course, dulness, but this varies much in degree, situation and extent. Obviously such impairment or loss of percussion sound is dependent in great measure on the seat of the growth. Involvement of lung and pleura by secondary conditions may completely mask the dulness arising from the original growth. I need only mention such morbid states as pericardial and pleural effusion, pulmonary collapse, and pneumonic consolidation of lung to remind you of the necessity for alertness in interpreting signs. In perhaps the majority of cases careful examination will detect dulness over a limited area, such district being usually in the upper and anterior regions of the chest, often crossing the middle line, although usually unsymmetrical in its extent.

Much valuable information may often be afforded by the sensation experienced on percussing over an intra-thoracic growth.

**Auscultation.**—Here again the greatest variation may occur, dependent on the site, extent and character of the growth, and the associated pulmonary and pleural lesions. Usually there is some alteration in the normal respiratory sounds. It may be nothing more than a raising of pitch and increase in harshness, or a weakening which may pass into complete abolition.

The sounds often vary much in different parts of the chest, and, of course, undergo much change in the course of the illness. When the lung is extensively infiltrated and the bronchi blocked, respiratory sounds will be annulled on that side. In such cases a puerile type is met with, probably on the opposite side. When a localised growth exists in the lung the breathing is usually bronchial or tubular, and may even have cavernous characters. When cavities form characteristic signs may be elicited, but this is by no means always the case. Adventitious sounds are not of much importance, and usually only point to some secondary bronchial involvement or co-existing pulmonary lesion. Pleuritic friction may sometimes be detected; but a rub from movements of mediastinal tissues is altogether exceptional.

Vocal, tussive and whispering resonance may undergo considerable change. There may be marked exaggragation and even an angophonic or amphoric quality present. Sometimes whispering pectoriloquy can be obtained over a pulmonary tumour.

**Mensuration, cymometric charting and like means for registering the size, shape and form of the chest are of considerable value in affording useful data for comparison during the progress of the case.**

**Skagiographic examination should now never be neglected.** A laryngoscopic inspection may also afford useful information. In some cases an exploratory puncture of the pleura may assist in
clearing up a diagnosis. As already indicated, investigation of the sputum does not usually afford very definite information, but it should not be neglected. In every case of supposed intra-thoracic disease the abdomen and pelvis may well be carefully examined, for it is necessary to remember that even when apparently primary in the chest it may subsequently prove to have been secondary to an initial growth in the abdomen or elsewhere.

The course, duration and termination of cases of intra-thoracic malignant disease vary considerably, as will be clear from our present study of pathological and clinical conditions. Usually the course is chronic and progressive, but occasionally cases are met with where an acute course is run.

Diagnosis.

Space will not permit me to enter into the very interesting and important discussion of the differential diagnosis of intra-thoracic malignant disease from the many other conditions which may simulate it—a complete study would, indeed, lead us into a research respecting most of the morbid lesions of the chest.

In forming a complete diagnosis we need to (1) distinguish intra-thoracic growths from other lesions which may simulate them; (2) Mediastinal lesions such as abscess and syphilitic disease. (2) Pulmonary affections: Acute disease of the lungs, bronchitis, pneumonia, tuberculosis, emphysema and chronic bronchitis, collapse of the lung, chronic pulmonary tuberculosis, and chronic pneumonia. (3) Pleuritic conditions. (4) Pericardial conditions, particularly in patients of hydro-pneumothorax. (5) Intra-thoracic aneurysm. It is impossible to discuss the points separately which should guide us in ascertaining precise seat and exact nature of the growth, but I would again insist on the necessity of basing our methods of discrimination on our knowledge of the actual pathological conditions.

Prognosis.

When the existence of an intra-thoracic tumour has been definitely ascertained the outlook is hopeless, and usually much suffering is the only prospect. Treatment is purely palliative, and nothing of permanent benefit can be expected from operative interference.

I have but outlined the leading features in the interesting but oftentimes perplexing study of primary intra-thoracic malignant disease, but I hope I may have at least awakened a desire to secure further light on this still but ill-defined section of pathology.

THE INFLUENCE OF ENVIRONMENT UPON WOMEN, IN ITS RELATIONSHIP TO OBSTETRICS AND GYNECOLOGY. (a)

By JOHN E. GEMMELL, M.B., C.M., House Surgeon to the Hospital for Women, and to the Ladies' Hospital and Lying-in Hospital, Liverpool.

At the outset it was contended that for accuracy in diagnosis in diseases of women, the knowledge of pelvic pathology alone was not sufficient; it was necessary to know all about their environment, their social and domestic conditions. During the past thirty years, whilst we have been studying the pelvis and its contents, the modern march of progress has completely altered the conditions and environment of daily life. The young lady of thirty years ago, whose attainments were not encouraged too highly and whose physical development received only scanty attention, was contrasted with the young lady of the present day, who is educated mentally and physically that she may be fitted to enter into competition with men, in order that she may earn her own living if necessary, and, further, that she may be able to participate in the out-door amusements and pastimes of men. As a result, women are physically taller, stronger and of better physique, and mentally sharper and more active.

He next considered how this had affected parturition, and asserted that as a result of the improved development labour in the better classes was effected in a much more normal fashion, and that as a result of the increased muscular development and constitutional condition of the woman, which largely obviated the necessity for their use; and also to the recognition of the risks of injury of the genital passages that even a skilful use of the forceps may cause, entailing possibly minor gynaecological work subsequently.

Physical culture is only injurious to women when it is overdone and pushed too far; he had never met with any abnormal or unhealthy pelvic condition due to reasonable exercise. The increased mental stimulation, whilst tending to give women more control over the nervous system, had, unfortunately, in many instances led to reflex pelvic disturbances, through over-activity of the nervous system. The intimate relation of the generative system to the whole organism was discussed, together with the increased frequency of neurasthenia and its resultant want of muscular and vasomotor tone, and its effects in the pelvis. On the question of dress, a great deal of nonsense had been talked and written—women would have to be allowed to work out their own salvation in the matter. The introduction of lawn-tennis, cycling, and the necessity for partaking in outdoor exercises had done more towards their emancipation in this direction than anything else. From the physician's point of view, doubtless, many evil effects were produced constitutionally from the effects of pressure, weight and the unequal distribution of heat, and these having produced ill-health would secondarily produce pelvic troubles; but from the gynaecologist's point of view, with the few exceptions of displacement of the pelvic organs from tight-lacing, he had never seen any case of pelvic disorder that could be directly attributed to errors in dress. The exciting causes of inflammation were infective and of bacteriological origin, not exposure to cold, &c., and the importance of strict asepsis in even digital examination was therefore emphasised.

The enormous increase in the employment of women in cities was commented upon, and the fact...
that the birth-rate had diminished pointed out. This diminution was accounted for partially by intention, but at the same time the most marked diminution was among the class whose mental and physical activities were ever increasing, and thus creating great demands upon the nervous system, with considerable loss of nervous energy; consequently, the cause may be natural.

Our intimate knowledge of the pathology and sequelae of pelvic disease opens up to us a large field of work in what may be called preventive midwifery and gynecology. Preventive midwifery is largely established and understood, and there has been a marked decrease in the puerperal mortality since 1881, yet from 1807 to 1900 there has been a slight increase in the number of deaths from puerperal fever. While allowing for cases of toxemia going on to sepsis, which may arise in the best conducted practice, possibly having origin in the bowel or kidney, and which can never be satisfactorily explained or guarded against, there should not be in these days of improved house sanitation and improved surgical methods and care in the death-rate from puerperal fever. The difficulty of getting nurses and student nurses, and even medical men, thoroughly to understand applied antisepsis and asepsis in the conduct of labour was dwelt upon, and the suggestion made that the care of the hands of the accoucheur was of the greatest importance, and especially the avoidance of direct contact with pus. The use of rubber gloves for the protection of the hands whenever attending to the dressing of ulcers and wounds, or where examination exposed the hands to contamination, was advocated, and stress laid upon the abdominal method of diagnosis and examination during labour. By instruction leading to the improvement of the individual we shall aid in preserving women for their superusers, the proportion and preservation of the race, and at the same time promote that race to a better standard, mentally and physically.

MILESTONES IN MEDICINE, (a)

BY SEYMOUR TAYLOR, M.D., F.R.C.P.Lond., President of the West London Medico-Chirurgical Society, and Physician to the West London Hospital.

In bringing before you as the subject of my address the great discoveries of recent times, which I have ventured to term "Milestones in Medicine," I would first ask your attention to the great stride which Ambrose Paré made when he introduced the ligature with which to arrest the haemorrhage from a severed artery. Up to his period medicine and surgery had not advanced—nay, it is probable that they had retrograded—since the time of the Greek school, for the Chirurgeon of that day did have some crude idea of applying a ligature to a generally oozing surface, although he had not ventured to tie a artery severed by a surgical knife, or by a spear in warfare. Hence it is probable that up to Paré's time the greatest mortality on the field of battle was due not so much to the shock of wounds as to haemorrhage which could not be controlled. Then came Paré with his simple strand of thread, and what a revolution he brought about, and how he raised the status of the surgeon, who, hitherto considered as a bungling artificer fit to rank only with barbers and chiropodists, now began to take higher rank. Consequently, and of almost of necessity, the tendencies were attractive to our profession. Nor is the benefit of Paré's discovery limited to the ligature, since a little thought on our part will show

that it is the parent of the snare, the écrasuré, and the clip-forceps which are in everyday use.

The next milestone is vaccinia. Till Jenner's great experiment of inoculating a youth with vaccinia, and then endeavouring, to inoculate the same youth with varicella (1796), the counties of England and other countries were at the mercy of a loathsome endemic disease, a disease which was regarded as a visitation from God, and no more to be avoided than a natural earthquake. Consequently, the mental attitude of the inhabitants of these counties was one of indifference or of resignation. Yet though Jenner's discovery altered all this, and although it was received with enthusiasm and gratitude by other nations, England, and especially the county of Kent, received the boon with opposition, in which ignorance, incredulity, and coarse vulgarity played equal parts. Vaccination was assailed by coarse libel, and by lewd caricatures common to the period. And even now, although a pro-marked visage is a rarity instead of being the facial characteristic it formerly was, and although the death-rate from varicella is infinitesimal compared with that of the times before Jenner, we still allow a noisy, ignorant, because scientific, press to so influence our Legislature that much of the benefit of vaccination is thrown away. I say, and I say it advisedly, that we ought nowadays to have no knowledge of varicella, except what we had in the way of models or from pictures, and that this happy state of affairs could be brought about by strict vaccination and re-vaccination.

The stethoscope is my next milestone. Till Laennec time (1819) any attempt to explore the regions or to diagnose the physical state of the contents of the chest was entirely restricted to percussion. Yet when the great French clinician published a quire of paper and listened to the patient's chest, what a discovery it was made! He converted our eyes into penetrating rays, and our fingers into medical probes. Yet here again a great discovery was met by opposition, by scorn, and by ridicule at the hands of ignorant and indolent members of our profession. One physician declared that the stethoscope would not enable him to diagnose a pneumonia; it was by another called a medical horn; so that, looking back to this ignorant opposition, it seems strange to us that we now consider one of the most powerful weapons which we wield in our fight against disease should have had such a cold welcome from our forefathers. And yet I venture to think that there has been no revolution more made on the simple tube which was devised by Laennec.

Anesthesia next claims our attention. The lay public at once pronounces chloroform as the greatest benefit which medicine has secured for suffering humanity. Centuries ago attempts were made to lull the pain of the knife. Mandragora, Indian hemp, and opium have all had in past ages their advocates, and have all been discarded as anaesthetics, in some instances because the drug was useless in the required direction, in others because it was supposed to be dangerous. Then, after centuries of darkness, chemistry discovered certain gases which could send people to sleep. Here are the stages of this most momentous discovery: Nitrous oxide, discovered by Priestley in 1774. Davy suggested it as an inhalation, but his suggestion was ignored. Then Wells, an American, in 1844, used the gas with success during a dental operation. In 1846 Morton substituted sulphuric ether; and finally Simpson, of Edinburgh, in 1847, hit on chloroform as the safest anaesthetic for prolonged operations, and with many practitioners this opinion is still upheld. Now this priceless boon of anaesthesia comes entirely from the Anglo-Saxon race. The anaesthetic property of certain vapours was proved in England, tried in America and in Scotland almost simultaneously, and subsequent discoveries of importance such as apparatus, to technique, and to mixture of vapours have been made in Britain by our Closers, our Snows and our Harleys. The advent of anaesthesia was literally a revolution, a contest of opposition and ridicule compared with that of other great medical discoveries.

(a) Abstract of the Presidential Address delivered at the opening of the West London Medico-Chirurgical Society for the Session, October, 1895.
The last milestone, antisepsis, has been erected by our great teacher, Lister, who, happily, is still with us. Until the year 1868 the death-rate from amputation in the general hospitals of our large towns was appalling. I can remember, on my first introduction to the profession, that healing by primary intention was almost unknown. About the jaundice the term was not in common use, and after an amputation one had to exert one’s ingenuity towards bandaging a gaping, offensive, suppuring stump from which the wire sutures had sloughed away. The patients died, not from the disease itself but from shock due to, the amputation, but from pyaemia, gangrene, erysipelas, and other forms of blood-poisoning, which, present in the atmosphere of the hospitals, entered the flesh at the same time as did the knife.

Then Lister built up the germ theory of the lobe of the liver, based on the researches of Pasteur. He showed us how to treat wounds so as to exclude the pernicious atmosphere of the hospital wards.

The discovery of antisepsis, notwithstanding its scientific foundation and its successful practical proof, was received with incredulity by some, with satire by others. Yet, as Lister himself said, antiseptic surgery must be adopted by the profession; so that to-day no surgeon of eminence dreams of performing an operation without carrying out the principles of our great teacher. Thousands of lives are annually saved, and thousands of sufferers are cured of hitherto incurable diseases by Listerism. We should regard Lister as the greatest benefactor of mankind whom the Victorian era produced. Let us not forget these great discoveries; let us remember the debt we owe to our predecessors, but let them stimulate us all to further research, so that we may hand down to succeeding generations a debt not similar, not diminished, but, rather, augmented, for we have received a great inheritance.

Clinical Records.

SAMARITAN FREE HOSPITAL.

Large Bile-Cyst of the Liver.—Jaundice without Cholelithiasis.—Incision and Drainage.—Recovery. (a)

Under the care of ALAN DORAN, F.R.C.S., Surgeon to the Samaritan Free Hospital.

The patient was a woman, aged 42, who was admitted into hospital with jaundice and enlarged liver. Three years previously she struck the right hypochondrium against a tub when in the second month of pregnancy; and her condition followed within a few hours. Some days before admission jaundice appeared and the motions became white. A large cystic swelling was exposed by Langenbuch’s incision. It contained three pints of green bile without calculi or hydatid elements, and occupied the right lobe of the liver. The gall-bladder, hepatic, cystic and common ducts were empty, unobstructed and quite unconnected with the cyst, which was drained. Much pure bile escaped for three weeks, the jaundice disappearing. By the fourth week the motions became coloured. Seven months later the patient was in good health, a little pus escaped from the drainage track.

There are other reported cases of a single non-hydatid and non-pedunculated cyst in the liver. In Bird’s, Mayer’s and Winkler’s cases there was neither jaundice nor cholelithiasis, and in Winkler’s alone was there any trace of bile in the contents of the cyst. In Ricord’s cases the cyst was jaundiced, whilst the common duct contained calculi. There was apparently bile in the contents of the cyst in Northcote’s case, whilst in Robson’s bile flowed away a few days after the cyst had been operated upon. In the author’s case there was marked jaundice, but no trace of cholelithiasis; the cyst contained pure, unduluted green bile. The author recorded some observations on gall-stones in the liver.

In this case, the cyst was possibly developed after the injury, or due to pregnancy, which is associated with biliary stasis (Potocki), or to their combined action. It might, however, have been a true new growth, but such cysts do not usually contain bile. There were no distinct symptoms of hypertrophic biliary cirrhosis. Some observations were made about congenital malformations and heredity (Parkes Weber), about the jaundice the precise cause of which was not clear in this case, about hemorrhage in operations on jaundiced subjects; about the prophyactic power of chloride of calcium, and about the dangers of hemorrhage into liver cysts (Allen and Kilvington). The influence of jaundice on menstruation was noted; in Cocking’s case of life-long jaundice the patient bore children and was regular; in the author’s case there was neither amenorrhoea nor menorrhagia. Drainage was the right treatment for a non-pedunculated liver cyst. In this instance, where cholelithiasis and pancreatic disease were absent, there was neither shock nor poisoning after the operation. It was difficult to keep the drainage track and adjacent part of the abdominal wound aseptic.

Transactions of Societies.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, OCTOBER 22ND, 1903.

RUSHTON PARKER, B.S., F.R.C.S., President, in the Chair.

Mr. Newbolt showed a male patient, aged 64, from whom he had successfully removed a large simple papilloma of the larynx involving the right vocal cord. Thyrotomy was immediately preceded by tracheotomy. The tumour had been growing for six years. Dr. Binns exhibited a neat, convenient, and efficient portable metal operating table, designed by Richelot, and made by Mathieu, of Paris. The Trendelenburg position of the patient was readily secured.

Mr. Busby showed a case of aneurysm of the ascending aorta in an unmarried woman, aged 26. The condition had existed for the past eight years. He also showed an unusual form of heart affection in a young man.

Dr. Gullan suggested that the systolic retraction of the sixth and seventh intercostal spaces might indicate adherent pericardium and mediastinitis in the second case.

Dr. K. Grossmann gave a paper on the QUANTITATIVE EXAMINATION OF COLOUR VISION from the point of view of the practical requirements of recognising coloured signals. These requirements were analysed, and the desirability of the examination with coloured lights was emphasized. Congenital and acquired colour blindness were considered; the former involved the whole field of vision, the latter often only parts thereof. The most frequent and the most dangerous form was the defect of the fovea, central colour scotoma. It was often caused by toxic influences—e.g., by tobacco, and was infinitely more frequent than generally assumed. Its existence was not detected by the ordinary tests, especially not with Holmgren’s wool skeins. The exact frequency of occurrence is not known, as it is rarely looked for.

Dr. Grossmann then described and demonstrated his test for the examination of colour vision, and the principles underlying its construction. Starting from any given standard colour, distance, size, and intensity of light can be arranged so that the elements for a quantitative scale of colour perception are thereby given.

Dr. E. Nicholson said the greater number of cases showed simply confusion between green and drab or dark grey, about 1 per cent. of men being thus affected. The graver form of color blindness, green and red, is not more than one-tenth as common. The green-drab effect is of little consequence to seamen or railway men, except in some foggy states of the air, when green may be mistaken for a bright light more safely than in the case of a person with normal vision. For the estimation of this defect, Dr. Grossmann’s method promises to be most useful.
Dr. W. Blair Bell read a paper on some points in the diagnosis of appendicitis.

He dealt with the differential diagnosis of (1) appendicular colic; (2) of acute appendicitis, pointing out, inter alia, that in the latter great care was necessary to exclude tubal and ovarian trouble when the patient was a woman. He also urged that when acute perforation had occurred it was possible to localise the site of the lesion when general abdominal pain and rigidity were produced by nothing, as the anaesthesia permitted of the muscle area which retained its rigidity longest. He had found that area to be situated over the lesion.

(3) Chronic appendicitis he distinguished from intermitting relapsing appendicitis. He considered that true chronic appendicitis was preceded by a primary dilatation of the cæcum, possibly by a chronic typhilitis in most cases; it was found almost entirely in the upper classes, being due to improper and over-feeding and "bolting" meals, a state of affairs which, when accompanied by constipation, inevitably, unless cured, led to infection of the appendix. Dr. Bell related cases in support of the various points he had mentioned.

The President, while the difficulty in diagnosis was sometimes due to the variable situation of the appendix, which in one case might cause a pelvic abscess and in another an abscess in the neighbourhood of the liver, observed that trouble was almost invariably mechanical, facæ and facæ concretions becoming impacted in the appendix. The milder phases of the complaint could not usually be diagnosed with absolute certainty; whilst the acute forms could always be recognised by pain, rigidity, and as such receive appropriate treatment. He thought it was not always possible to assert that the appendix was the source of the mischief in some cases without laparotomy.

The President, after complimenting Dr. Blair Bell, remarked that even "fulminating" cases with widespread peritoneal infiltration were not all fatal, as he had experienced on several occasions; also that cases around the appendix bounded by peritoneal adhesions, were commonly less difficult to manage successfully than abscesses occupying a retro-peritoneal or retro-caecal position, the former commonly being a more forward position, nearer the incision in the abdominal wall, and being easier to isolate during operation by packing and protecting the surrounding free peritoneum. In some cases the appendix could not be found or reached without creating more danger, but for all that are capable of healing and soundly closing. The cases of relapsing appendicitis were commonly unattended by abscesses, and the operation less urgent even when thoroughly advisable. There was also an important class of cases in which the relapses of pain were so clearly at a distance from the appendix as to be attributable to the dragging of adhesions. In these the operation would be dispensed with, as the appendix itself had actually recovered. There were others in which the relapses became less severe, and eventually ceased, so that here again operation was unnecessary.

He gave instances under each category, and had met with several varieties during the current year, in which numerous cases seem to have occurred in his own practice as in that of others.

NORTH OF ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY.
Meeting held at the Medical Institution, Liverpool, Friday, October 16th, 1903.

Dr. J. E. Gemmell, President, in the Chair.

The following card specimens were shown:—

Dr. J. B. Hellier (Leeds): Adeno-carcinoma of fundus and cervix uteri, removed by abdominal pan-hysterectomy from a single woman, set 50.

Professor H. Briggs (Liverpool): (1) Large fibroid showing the impossibility of enucleation, treated by abdominal hysterectomy. (2) A recent pregnant dolus in a case in which both Fallopian tubes were apparently completely closed. (3) A mixed dermoid (containing hair) and a cystic adenoma of the ovary. (4) A small ovum, seven days old, expelled in a decidua. (5) A small fleshy mole in its decidua.

Dr. Arthur Wallace (Liverpool): Multilocular cystoma, ovarii (twisted pedicle), which contained watery pink fluid resembling a weak solution of permanganate of potash. (2) Corpus uteri with very large right hydrosalpinx and left pyosalpinx.

The President showed a series of pen and ink drawings illustrating gynaecological operations.

Dr. Blair Bell (Liverpool) showed "nest-spring" reels for silk and catgut ligatures, with portable stinger and container.

CASES.

Dr. Lloyd Roberts (Manchester) related a case of intra-uterine fibroid, with extensive attachments to the interior of the uterine cavity. The tumour was attacked per vaginam, and one-third easily removed, but the remainder only with difficulty by morcellation. Towards the close of the operation the uterus became inverted. Recovery. Two questions were submitted: (1) Would it have been better, in view of the fact that the operation lasted two hours, if the uterus had been opened per abdominam, for Cesarean section, and the tumour enucleated? (2) Would it have been better to have performed hysterectomy, and removed uterus with tumour?

Professor Briggs (Liverpool) had had an experience of over fifty cases of vaginal enucleation, exclusive fibroid polyps. Given accessibility, there are two important considerations: (1) The difficulty of enucleation on account of bands and columns connecting the fibroid with the tissues of its bed; some fibroids cannot be enucleated in the strict sense; (2) the shape of the fibroid growth rendering morcellation an awkward task. When extensive morcellation was needful a large growths, a strong pointed bistoury effective, the work better than scissors, and the bistoury should attack the right and left of the tumour alternately so as to reduce the growth to a chain-like mass which would descend like a corkscrew. It was an error to manipulation to attack the lower portion of the growth and leave the upper half like an inverted full basin. The whole growth should be divided freely by the bistoury passed from side to side deeply. Hemorrhage from the uterine envelope could be controlled completely by traction on the tumour. The operation as described by Dr. Lloyd Roberts was often difficult and tedious, but the surgical means were justified by the success ensured by free drainage or removal of unnecessary division or sacrifice of the patient's tissues.

Professor W. J. Sinclair (Manchester) related a case of cesarean section, successfully performed for the third time on the same woman. The previous operations have been reported. On this occasion the foetus lay transversely. The incision opened the peritoneum a little, and there was some trouble from hemorrhage afterwards. The patient made a good recovery.

Dr. Nathan Raw (Liverpool) remarked that he had himself performed Cesarean section twice and embryotomy once on the same patient. He commented on the difference observed by different operators with regard to utero-parietal adhesions. Dr. Sinclair seemed to invite adhesion, but the speaker was not sure that there was any advantage to be gained by such a procedure. He was glad to know that Dr. Sinclair held the same view regarding adhesions, which contained himself, viz., that it was not part of the operation to remove ovaries or tubes. He would go further and say that it was unjustifiable for any operator to sterilise the patient, even although she gave her consent.

Dr. Lloyd Roberts also spoke, and Professor Sinclair, in replying, said that he always aimed at the production of adhesion of the uterus to the abdominal wall by rubbing iodine over the peritoneum, and by the application of pads under a firm binder.
The President delivered the Annual Address. After reviewing the work done during the earlier portion of the Session he proceeded to discuss the influence of environment upon women, in its relationship to obstetrics and gynecology, a full chapter of which will be found in another column.

Dr. Lloyd Rees [M.A., M.R.C.S., and Dr. J. B. Hellier (Leeds)] seconded a cordial vote of thanks to the President for his address. The President thanked the Society, and the proceedings terminated.

THE THERAPEUTICAL SOCIETY.

The first annual meeting of this Society was held in the Apothecaries’ Hall, London, on October 27th, Sir William Theslef Dyer, of Kew Gardens, in the Chair.

The following officers of the Society were then unanimously elected:—President, Sir William Theslef Dyer. Vice-President, Dr. J. Rose Bradford, Treasurer, Dr. S. C. Griffith, Secretary, Dr. T. E. B. Brown; and Members of Council, Dr. J. H. Bryant and Messrs. Peyton Beale, C. Dennis Vinrace, and W. Chalmers.

Dr. Harrington Sainsbury then read a paper on the action of bodies in the particulate state, with special reference to the action of carbon, of which the author gave a short abstract of the importance of the physical state of aggregation as a factor in the action of medicines on the tissues. Given an affinity between the substance and the tissues, the action depends upon (1) the vibration rate of the particles; (2) the density of molecular space; and (3) the extent of surface presented by the substance. The three states of matter, solid, liquid, and gaseous, contrasted in respect of these qualities. Conclusion, the liquid state is the most active state of the solid (in proportion to the insolubility of the substance) the least active state. Analysis of the action of solid bodies in the tissues, according to the substances are (a) soluble but not decomposable, (b) insoluble but partly decomposable into a soluble substance, or (c) wholly insoluble and wholly unchangeable. Carbon is a type of class (c). Consideration of its mode of action by virtue of its mechanical action, and also of its powers as an absorbent, shows that neither of these explains the effects produced by carbon. Details of experiments in evidence of the small part played by absorption demonstrate that the action of carbon must depend principally upon a substance reacting in some 150° no fewer than twenty-five times. Sir William Theslef Dyer proposed a vote of thanks to the author for his very interesting and valuable paper on the molecular action of carbon, which, in his opinion, resembles the chlorophyll, carboxylic acid, and watery vapour, forming the nutrient material of plants under the action of light.

Dr. Ince seconded the vote of thanks and proposed also a vote of thanks to the President, not only for his having presided on that day, but also for his very interesting and lucid speech.

These votes were unanimously agreed to.

After the meeting Mr. Chattaway showed a splendid apparatus for photographing the potassium tritide, and made some experiments with the X-rays and high frequency currents.

Dr. Sowerby, of the Regent’s Park Botanical Gardens, showed some interesting specimens of Chinese medicinal teas and of drugs and medicine plants. The Guildhall Library exhibited books relating to the Apothecaries’ Company, and the Apothecaries’ Society showed their collection of silver plate.

Messrs. Christie and Co. exhibited a diagnostic lamp for surgical purposes, and specimens of Velvated and Crisate tissue, also Anthropes.

And Messrs. Down Brothers showed intubation tubes for the bronchi and numerous diagnostic and surgical instruments.

Mr. Sydney Denton contributes to the November Temple Bar an interesting biographical study of “Thomas Linacre, M.D., a Medieval Master of Medicine.”

LUNACY IN LONDON.

The Annual Report of the Asylums Committee of the London County Council affords much interesting reading to the medical as also to the lay community.

A large increase in the number of certified lunatics has again to be recorded. The figures on which the report is based, with the corresponding figures of last year, are as follows:—

<table>
<thead>
<tr>
<th>Year</th>
<th>Asylums and licensed houses</th>
<th>In imbecile asylums</th>
<th>In workhouses</th>
<th>With relatives and friends</th>
</tr>
</thead>
<tbody>
<tr>
<td>1903</td>
<td>16,685</td>
<td>5,877</td>
<td>408</td>
<td>168</td>
</tr>
<tr>
<td>1904</td>
<td>16,950</td>
<td>5,937</td>
<td>408</td>
<td>156</td>
</tr>
</tbody>
</table>

It will therefore be seen that, in every class there is an increase. Only once in the last fourteen years has there been a decrease recorded; this was in 1901, when there was a diminution in the figures of 10 to the extent of twenty-four. The increase between 1890 and 1903 reaches the enormous total of 6,594, which is out of all proportion to the increase in the population. Had the increase in lunacy merely kept pace with the increase in population the number of unregistered lunatics should only have been 17,900 instead of 22,952. There is doubt, however, if this apparent increase in lunacy, out of proportion to the population, is real, for whereas we now a considerable number of unregistered lunatics live with their relatives and friends, nowadays there does not seem to be the same reluctance to take advantage of asylum treatment. It is now generally recognised that asylum patients have every comfort and care bestowed upon them, and the best of medical treatment constantly at hand. The result is, children do not now hesitate about having an aged parent certified insane and removed to an asylum, whenever they show the slightest symptoms of senile insanity and require any special care. Doubtless such cases tend largely to increase the number of certified lunatics—cases which formerly were treated at home, and never certified insane.

The number of persons over seventy and admitted to the London county asylums during the last four years was 590, and in many cases the patient’s death has been hastened by removal to the asylum. Among these 590 no fewer than two hundred and thirty-five were within fourteen days of admission, fifty-one within a month, 187 within a year, and 254 in the four years. Surely much could be done to remedy this by the medical man called upon. The asylum is often the first resort of cruelty to the patient, and a real grievance to the ratepayer.

The task of finding accommodation for this ever-increasing insane population is naturally causing the Council authorities much anxiety. Year after year reforms are suggested which would release from their control a number of lunatics, who could with advantage, and with greater humanity, be accommodated elsewhere. Rightly they appeal for a reduction of the number of very aged persons sent there; also that more of the harmless patients transferred from the workhouses should be kept there. The remedy for this we suggest, namely, a night staff. Invariably the certified insane for removal to an asylum from the workhouse is: patient is restless and talkative at night; tries to turn out the gas, or some other such cause. This could be obviated by having a night staff, at a cheaper rate than having the patient removed to, and kept in an asylum.

Mental pathology continues to be prosecuted with much zeal in the asylum’s laboratory by Dr. Mott. The second volumes of the Archives of Neurology, important papers by Dr. Mott on “Tabes in Asylum and Hospital Practice,” and by Dr. J. O. Botten, assistant pathologist, on “The Histological Basis of Amentia and Dementia.” The volume of 652 pages
We were particularly struck with the air of homeliness which pervaded the place, and the lack of the stiffness and formality which marks so many institutions. We had the privilege of spending a day and night in the sanatorium, and thoroughly inspected all parts, as well as watching the routine work of the establishment, and being present at the meals of the patients.

The building, as may be seen from the accompanying illustration, consists of two wings inclined at a wide angle extending from a central main block. The diverging limbs have aspects south-south-east and east-south-east. The sanatorium is but one room and corridor deep, and consists almost entirely of bedrooms. All patients’ rooms face S., and S.E., and as obtain the maximum of sun with the minimum of wind. No verandahs have been erected in front of the rooms, and each apartment is consequently free exposed to sun and air. Each room is particularly attractive, simple in its adornment, absolutely despotic in its hygienic furnishing, and supplied with everything essential to the well-being of the occupants. The bedrooms are such as seem to combine the efforts of an ordinary habitation with the advantages of an outdoor life. In addition to the open window which occupy the greater portion of one side of each room, there is also free ventilation into the corridor. A few rooms are specially large, with bow-windows and fireplaces. Every room is fitted with electric light, bell, and special plug for electric current for therapeutic use or other purpose. The beds are very comfortable, and the basins and jugs are of small size, particularly suited to the needs of delicate people. No pipes in connection with the washing conveniences appear in the room.

The corridor behind the patients’ bedrooms is well lit and perfectly ventilated by abundant windows. The flooring is of tile and free from the unseemly spaces only too often visible in wood flooring. From the north side of the corridor on the ground and first floor of each wing project pavilions containing earthclosets and bath rooms. At either end of the building is a nurses’ room.

A central open-air gallery is situated on the ground and first floors, and the doors of the bedrooms have been so made as to allow of the ready removal of a bed, with patient in it if necessary, on to the gallery. The central position of the gallery secures protection from winds, and it is thoroughly ventilated and well fitted with electric light. The staircases are particularly attractive in their artistic design, and of...
such a gradient as to afford no distress to patients using them. Two rooms near the centre are occupied by the resident medical officer and lady superintendent, and are flanked by the entrances of the two staircases, so placed as to permit of a ready oversight of the patients. The rooms on the top floor, though smaller in size, are also attractive, and are occupied by nurses and their servants' quarters. At one corner of the forecourt is a small open-air gallery. Much praise should be given to the very excellent dining-hall. It is an almost ideal room for its purpose, and we found it absolutely free from the stuffiness which is often found clinging about a dining-room, even in a sanatorium.

The electric installation is particularly complete, and there are two large boilers. The building is heated throughout by steam at low pressure, and has its own laundry. There is also a well-lit dispensary and pathological laboratory. We noted that the former was well supplied with all modern drugs considered to be of service in the treatment of tuberculosis. The mortuary, although probably but seldom used, is well equipped and suitably situated.

There is a very abundant supply of pure water. We were much struck by the admirable arrangements by which hot water is always available. As already indicated, earth-closets are used, and waste water is dealt with by a satisfactorily established system of sub-drainage. The ground around the sanatorium has been planted, under the direction of a well-trained lady gardener, with a large number of firs and larches, which will afford much shade. In front of the building is a terrace and wide lawn. Gardens, six acres in extent, face S.E., and are well sheltered by trees and high hedges, and paths of varying slope afford opportunities for various exercises. Sheds and seats are provided in abundance. The estate comprises a total of ninety-four acres. There is a farm on the land, from whence all milk and cream is obtained.

Treatment is based on the Nordrach lines, but all hygienic and dietetic requirements are carried out on rational lines, and in accordance with strict scientific methods. The daily régime of the sanatorium is as follows:—Before breakfast the doctor visits all patients at 8 a.m. Those patients who are well enough to be out and about take their prescribed amount of exercise some time between breakfast and 12 o'clock, at which hour all patients lie down till dinner at 5 p.m. Dinner consists generally of three courses, followed by fruits, bread and butter. After dinner patients again take regulated exercise; have tea at 4 p.m.; rest for an hour before supper, which is at 7 o'clock, and is rather a lighter meal than dinner, and followed by tea or coffee for patients desiring either.

Accommodation is provided for thirty-five patients. There is a resident medical officer, a lady superintendent, and a good staff of experienced nurses. Dr. Jane Walker, of 122 Harley Street, London, is the medical director, and frequently visits the Sanatorium. Terms, inclusive of everything, except laundry, drugs, and wine, range from four to six guineas a week, according to the room occupied. The Sanatorium is near Nayland, seven miles from Colchester, and three and a half miles from Bures Station (G.E.R.), where patients are usually met. The average train journey from London (Liverpool Street terminus) is from one and a half to two hours.

Reference should also be made to the excellent pioneer work which Dr. Jane Walker has accomplished, and is still developing, in the interests of consumptives who belong to the so-called "working-classes." As far back as 1893, a cottage for female cases was opened at Downham, in Norfolk. In 1898 Calix College Farm, at Fordham, adjacent to Downham, was adapted as far as was possible to the requirements of sanatorium life; other rooms in the village were also taken and modified to meet the demands of the numerous applicants. At the present time poor cases are being treated in accordance with hygienic methods at Clare, at a weekly charge of 15s. At the farm at Nayland a small number of men can be taken for two guineas per week.

Dr. Walker proposes very shortly to secure additional accommodation for this class of case, and it is to be hoped that before the close of the Thoroughfare poor will be available for the many cases for whom no provision can be found save in the much dreaded and usually quite unsuitable workhouse infirmaries.

[FROM OUR OWN CORRESPONDENT.]

PARIS, November 1st, 1905. PLACENTAL OPHTHALMOPHARYNGITIS.

M. Bouchacourt, in speaking on the above subject, said that he could not agree with M. Fieux, who declared that if the placenta given to cows increased the secretion of milk it should not be interfered with, as the same treatment could be applied to women, who differed in many essential particulars from the lower animals. He, the speaker, considered that a certain correlation existed as regards the efficacy of the treatment. But, on the other hand, he would exclude the glycerine extract of the human placenta as being utterly unfit, as the glycerine drains the tissues on the foetuses and might have a toxic effect; also, such preparations could only be administered hypodermically; consequently, he had abandoned them completely. On the other hand, he was convinced by repeated experiments that large doses of the placenta stimulated considerably the mammary secretion in nursing women.

As to the employment of placental preparations in the treatment of chilblains, he was unable to form an opinion, although it has been practised in China for centuries.

TUBERCULOSIS OF THE KNEE.

M. Gaugolphe said that before practising resection of the knee, the temperature of the patient should be taken carefully for several days, as by its precarious treatment was frequently revealed. He refused also to operate on patients suffering from albuminuria or suppurating osteo-arthritis.

Of eighty resections performed by him within the last sixteen years, he had only had two deaths from the operation, and three patients had died within the year from consumption. M. Lucas said that the shortening, produced by resection was infinitely preferable, as regarded walking, to ankylosis preserving the length of the limb. Consequently, he resected each time that he feared ankylosis. M. Frolich said that resection was very suitable to adolescents, he did not speak of children, in whom the white swelling got well spontaneously; but in the adult, especially in hospital patients, he preferred amputation.

TREATMENT OF COMPLICATED FRACTURES.

M. Van Stockum read a paper on his method of treating wounds, and notably complicated fractures, by impregnating the wound with Peruvian balsam, a treatment employed by one of his predecessors, M. Van der Hoeven.

After removing all the foreign bodies which might be found on the surface of the wound, and without washing the parts, he filled the fracture wound with sterilised Peruvian balsam. The fracture is then reduced and an antiseptic dressing applied. The results he obtained were excellent. Out of ninety fractures thus treated only three suppured.

SIMPLE JAUNDICE.

Professor Robin, in treating idiopathic jaundice,
excludes the usual antiseptics given by many on the faith of the microscopic theory of the affection, such as naphthol, salol, &c. He orders an absolute milk diet, which produces diuresis and eliminates the biliary and intestinal toxins. This diet should be continued until the patient had lost all yellow colour, that is to say, for a considerable period, as the icterus persists a long time. To know, however, the exact time for the modification of the treatment the urine should be tested. If by the Gmelin reaction no green colour is produced, the biliary canals are free; the presence of urobilin (walnut-colour) indicates insufficiency of the liver, consequently the organ should be stimulated by an alimentary régime and the use of alkaline water.

In order to facilitate the flow of the bile, Professor Robin gives one-fourth of a grain of belladonna extract morning and evening, while twice a day he had administered three pints of cold water as enemas.

The alkaline treatment consists in bicarbonate of soda, a laqoons, and, taken at the close of six ounces four times a day, for poor patients, and in Eau de Vichy (Haute rivie) two glasses in the morning at half hour intervals, and two in the evening, for the better classes.

The food should exclude fat, acids, butter, ragouts, sauces, &c. Constipation should be treated with sulphate of soda, three or four drachms in salt water.

Germany.

FROM OUR OWN CORRESPONDENT.

BERLIN, October 31st, 1908.

At the Surgical Society, Hr. Steiner, Berlin, read a paper on THE OPERATIVE TREATMENT OF CHRONIC DYSENTERY.

The surgical treatment of this disease was of most recent date. The few results hitherto published were on the whole not favourable. The operations themselves were of different kinds. The case reported was one of considerable interest. A single woman, aged 36, had suffered from dysentery for nine years. It began as painful diarrhoea, and later on mucus, blood, and pus made their appearance. The disease gradually got worse, fever came on, and the patient became reduced to a dangerous degree of cachexia, so that finally an ileostomy was proposed. Laparotomy was performed in the spring of 1901. The serosa of the whole colon was thickened in patches. An anus preternaturalis was formed close to the valvula Bahnini, so that faeces no longer passed through the colon. The bowel, thus freed from function, was washed out daily, first with six to eight litres of warm water, then with a solution of tinct. iodi, or protargol. The ulcers in the large intestine were in this way brought to heel in about six months. The anus preternaturalis was then closed temporarily, and after it was seen that the passage of faeces did no harm, it was finally closed by operation. Since the last operation a year had elapsed, and the patient remained quite healthy. The profuse purulent bloody stools had ceased altogether, and the faeces were passed once a day, and without pain. The strength had returned, and the weight had increased, and the patient was now able to follow her employment. By following out the method of treatment described above, the disease, which had hitherto been held to be incurable, afforded better prospects as regards treatment for the future.

A Surgical Congress, Hr. Hahn, Nürnberg, reported a case of Rupture of the Biliary Passages.

A boy was admitted into hospital with collapse and jaundice, but without anything further being known. Examination showed two encapsulated exudations, and the question was whether they were tuberculous or hemorrhagic. Incision in the middle line revealed pure bile in the abdomen, immense calculous masses and adhesions. Both liver and gall-bladder were covered with cicatrices. A tampon was introduced and the edges of the wound brought together on account of the collapse, which had further increased. Then came some history. Six weeks before the boy had been run over, then jaundice came on, which gradually got less, then the little patient suddenly collapsed. After some days he rallied, so that a second operation could be proceeded with. There were firm adhesions of intestines, but as the overflow of bile rendered accurate inspection impossible, the speaker had again to content himself with tamponade. After this normal conditions returned, and the boy was now well.

Hr. Völcker, Heidelberg, introduced the subject of TREATMENT OF HYPERTROPHY OF THE PROSTATE, and the discussion that followed showed that opinions on the subject are still divided. A patient in Czerny's clinic, aged 66, had suffered from bladder troubles since 1886, and in 1895 went to the surgical clinic with cystitis, and there had the high operation performed. Latterly prostatectomy had been performed in eleven cases in which catheterisation had failed. In case a hypertrophy of the whole prostate Bottini's operation was useless.

As regards the anatomy of the hypertrophy, the most usual form was the glandular; then followed the mixed form, with connective tissue; the fibrous form gave the smallest percentage. The first form had the greatest possibilities of growth, and here recurrences easily took place after Bottini's operation. Occasionally one saw transition into a malignant form, and these were not so rare as had been believed; they were not to be recognised with certainty. The partially glandular form was suitable for Bottini's operation, the softer form for excision. Excision had been performed in eleven cases with two deaths, one from cardiac failure, one from sepsis after injury of the rectum. The treatment was concluded in eight cases. In three the rectum was injured, one with permanent union between rectum and urethra, one with contraction, and one with fistula remaining. Four had completely recovered.

Hr. Frenzemberg remarked that after Bottini's operation the bladder did not quite empty. The incision should be made forward and to the side. Severe haemorrhage might be set up if the instrument went too far forwards. It came from the bladder or from the paraprostatic tissues. He had lost a case from haemorrhage; he also mentioned an unfortunate case of rupture of the bladder during the operation. One patient died from chest symptoms. Out of 140 later Bottini operations he had no accident.

Hr. Schumacher was in favour of suprapubic excision.

Prof. Fedak said the high operation had not answered all the expectations; the dangers of after-treatment in old people were especially to be feared. He recommended incision through the posterior wall of the bladder in front of the rectum.

Hr. Schlocher recommended the abdomino-rectal extirpation.

Hr. Kümmler believed that with improved technique the operation had a great future before it. He had performed a series of such operations, especially as preliminaries for the separation of the meso-rectum. The abdominal wound was then closed and the operation ended pararecally.
Hr. Kraske, Freiburg, had also operated in a similar way.

Austria.

[From our own correspondent.]

VIEI-VIA, October 31st, 1903.

CHEST DISEASE AND RONTGEN RAYS.

At the Medical Society, Faulhaber, after exhibiting a number of instruments for taking photographs, pointed out the focal effects of a profusion of the signs in the thorax on paper, and their peculiar utility. From the different directions the rays entered and left the chest the appearance on paper would be different. For diagnostic purposes there were three angles which should be taken, viz., the sagittal, dorsal-ventral, and ventro-dorsal. By this means the so-called central shadow may be obtained which Weinberger has so clearly shown to be the real value of the rays in diagnosis. The diagonal rays, so-called Holzknecht, are also found to be useful in radiographic examinations of the aorta and oesophagus, but in many diseases of the thorax both methods were indispensable. He next showed a large number of projections which he had taken at the institute during the year. This series comprised changes in the heart and arteries, bronchial enlargement, aortic contractions, and valvular disease.

Empyema, pleuritis, pneumothorax, pulmonary cirrhosis and tuberculosis were those specially to be noticed.

AGRAMMATISM.

Pick related the history of a case of agrammatism in a female after confinement. He said authors were mostly agreed that agrammatism was not a disturbance in the centre of speech. In his case there was a general weakening of the brain, especially confined to the left temporal region or centre of speech.

The patient was 41, and shortly after her confinement of the ninth child she was suddenly attacked with a stroke associated with convulsions. The speech and other agrammatic characteristics were strongly pronounced till her death, some time after from pneumonia. The clinical diagnosis supported a diseased centre with softening of the brain, which had probably been the result of some puerperal toxin. An examination of the brain revealed extensive atrophy in the frontal lobes, particularly in the middle and posterior convolutions with the apex of the temporal lobe on the left side. A similar condition existed on the right. From this he reasoned that the process was agrammatism when the shrinking period arrived.

TREATMENT OF TETANUS.

Pfeiffer has recently been experimenting with antitoxin for tetanus. In 35 cases with Behring's antitoxin the mortality was 52.7 per cent. In 88 cases treated with Tizzoni's antitoxin the mortality was 35.8 per cent. It has shown the advantage of lengthening the incubation, advanced state of the disease, and the manner of injection are factors that modify the result of the serum. Pfeiffer subjoins 24 tetanus cases, 14 of which were treated without antitoxin, but were given narcotics, with 50 per cent. mortality. Again, six cases were treated with Behring's serum, with 22 per cent. recoveries, and three were treated with Tizzoni's serum, with no recoveries.

PHRYMONIC OSTEO-HYPERTROPHY.

Ceyhans records an interesting case of pleuritic affection associated with changes in the periosteum of the cylindrical bones, with hypertrophy of the tongue. The patient, 25, was, on examination, found to be suffering from effusion into the left pleura, but, on puncturing, diagnosis clearly confirmed it as a case of empyema pleurae dextra. According to the history, the nails began to curve and became claw-shaped three weeks after the invasion of the pleura. Several weeks later the tongue began to increase and become troublesome in the mouth. When attention was drawn to it by the patient it had assumed large proportions. No pain or other causes could be given to account for this enlargement. Taste and feeling, as well as palpation of the organ, were quite normal, and the only change observable was the limitation in movement from its size. In this case there were also changes in the periosteum of the long bones, which is not uncommonly found associated with pulmonary affections, but hypertrophy of the tongue is rather an unusual factor in the case. The analogy to acromegaly seems to be very close, although the explanation in this case appears to be of a toxic origin from the empyema, followed by changes in the nails, bones, and tongue.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

OPERATION FOR RECURRENT ABSCESS OF THE FRONTAL SINUS.—Mr. Mayo Collier operated for the third time on a case of abscess of the frontal sinus (the first operation was reported in "The Medical Press" some months ago). The case was interesting, he said, insofar as the abscess pointed in an unusual situation, the perforated orbit plate of the frontal bone in the centre of the orbit causing displacement of the eye downwards and inwards, accompanied by much oedema of the tissues of the eyelid and over the right frontal bone. The case, as stated in the previous report, was a large abscess of the frontal sinus, which perforated the orbital plate. After the first operation the parts healed and all discharge ceased. It was noted at the time that there was complete collapse of the right ala nasi, much enlargement of the right lower turbinal body, and a large depression on the septum corresponding to this enlargement. Mr. Collier said that he always had maintained that these affections of the accessory cavities of the nose were primarily in most cases due to mechanical congestion following defective nasal respiration, and this case bore out fully his contention; this was the third operation undertaken for the same condition of things, and he held that the cause of the relapses was due to his not having taken into consideration the primary cause of the trouble. The original affection of the frontal sinus was brought about by the congestion and consequent catarrh of the nasal cavities; this congestion and catarrh, extending into the frontal sinus, excluded the aperture of the infundibulum, the natural vent of the frontal sinus. He pointed out that it was not sufficient to open the frontal sinus, to curette its cavity, to enlarge its opening into the nose, unless the congestion and catarrh of the accessory cavities were removed also. The same argument was potent in reference to affections of the maxillary antrum; here also it was his experience that any stenosis of the nasal cavity kept up and maintained a chronic discharge of the interior of the antrum, and it was only after a free ventilation of the nose was effected that a permanent cure took place. Stenosis or narrowing of the nose, with no recovery, in all cases a state of negative pressure within the nasal and accessory cavities, and this meant chronic congestion of the entire lining membrane. Mr. Collier
LEADING ARTICLES.

Nov. 4, 1903.

The abdominal route because it enabled the surgeon to search for and remove any affected glands, and it gave him a better opportunity of freeing and removing the upper portion of the vagina when necessary, not to mention the advantages it gave in dealing with adhesions, although there were cases, in very obese patients, where the abdominal operation is practically impossible. Having freed the uterus from its attachments to the broad ligament and bladder, he had seen difficulty in finding where to open into the vagina, but the position of the latter organ could always be detected by the resonant note it gives on percussion if traction be made on the uterus. Coagulating from the vaginal flaps was, he said, sometimes a source of annoyance. This could always be checked by a running suture. The patient, he pointed out, was a young subject for this type of disease, but the clinical features of the fungating mass implicating the cervix, and bleeding readily on examination, left no doubt as to the nature of the malady.

The patient made an uninterrupted recovery.

CANCER HOSPITAL.

ABDOMINAL HYSTERECTOMY FOR CARCINOMA.—Mr. Charles Ryall operated on a woman, aged 25, who had been admitted with a foul vaginal discharge, which she had noticed during the past three months. It varied in consistency, was sometimes watery, brown, and blood-stained, and had a very offensive odour. There was no marked loss of flesh or strength, the catamenia had been regular, and she had had one child eight years previously. On examination, the cervix was found to be the seat of a large cauliflower growth; there was no apparent implication of the broad ligaments, and the uterus was quite movable. At the operation, the patient being placed in the Trendelenburg position, the abdomen was opened in the middle line above the pubes, and a search was immediately made for glandular infection. One enlarged gland could be detected at the bifurcation of the common iliac, and as it was quite movable the overlying parietal peritoneum was incised and the gland shielded out. No other enlarged glands could be found. The uterus was then drawn out of the abdomen and the upper part of the broad ligaments were divided and ligatured. The peritoneum on the anterior surface was divided just above the limit of the bladder, and this viscus was pushed down, thus freeing it from the anterior surface of the uterus and the upper part of the vagina. The uterine vessels were then traced down to where they cross the ureter, and here they were ligatured and divided. By the peritoneum the position of the upper part of the vagina was indicated, and then the vaginal vault was divided all round, completely freeing the uterus. Some oozing from the posterior vaginal wall was easily checked by a running suture, and a drain having been inserted into the vagina the anterior and posterior vaginal walls were brought together by a few more sutures. The operation was completed by closing the abdominal wall in three layers. Mr. Ryall remarked that he preferred the abdominal route because it enabled the surgeon to search for and remove any affected glands, and it gave him a better opportunity of freeing and removing the upper portion of the vagina when necessary, not to mention the advantages it gave in dealing with adhesions, although there were cases, in very obese patients, where the abdominal operation is practically impossible. Having freed the uterus from its attachments to the broad ligament and bladder, he had seen difficulty in finding where to open into the vagina, but the position of the latter organ could always be detected by the resonant note it gives on percussion if traction be made on the uterus. Coagulating from the vaginal flaps was, he said, sometimes a source of annoyance. This could always be checked by a running suture. The patient, he pointed out, was a young subject for this type of disease, but the clinical features of the fungating mass implicating the cervix, and bleeding readily on examination, left no doubt as to the nature of the malady.

The patient made an uninterrupted recovery.

THE ST. BARTHOLOMEW'S REBUILDING SCHEME.

At the commencement of the present year it was announced by the authorities of St. Bartholomew's Hospital that they had bought a large adjoining piece of land with a view of extending the Hospital premises. The actual cost of the ground was about a quarter of a million sterling, a sum that in itself might well give pause to the most sanguine and open-handed philanthropist. The proposal had already given rise to prolonged discussion as to the advisability of retaining the Hospital in its present site. Our own opinion was emphatically recorded in favour of removing this ancient charity to some suburban site, where land is cheaper, where resident populations are more crowded, and where the conditions of environment would be more salubrious. The tendency of London is to decentralise daily, and for its inhabitants to gravitate centrifugally to the outlying districts away from the City centre, which is now practically occupied by a day
LEADING ARTICLES.

MUDDLING THROUGH.

The public have just been treated to an egregious sample of the process of "muddling through" by a public department, and we really feel it our duty to call attention to a similar exhibition on a smaller scale by an important, but less conspicuous, body—to wit, the Metropolitan Asylums Board. To this heterogeneous collection of persons, representing nobody in general and nothing in particular, is entrusted, inter alia, the preparation and maintenance of accommodation for the infectious sick of London. Of all infectious diseases thus entrusted to their care small-pox is the most important, both from the public alarm it excites and the deadliness of its visitations. It need not be argued here whether small-pox epidemics should occur in London; the fact remains that under the present vaccination laws outbreaks of small-pox must occur from time to time. The Metropolitan Asylums Board have nothing to do with preventing small-pox; their function is to prepare for epidemics and find beds for small-pox patients when required. How was this duty performed during the recent outbreak? A glance through their annual reports for the last few years does not afford a reassuring answer to the question. In 1893, the last year that there was any considerable quantity of small-pox in London, the number of beds available was dangerously low. After that year small-pox fell lower and lower, and the apathy of a fool’s paradise seems to have thenceforth influenced the policy of the Board. That they were not left unwarmed of their precarious position may be seen from the annual published reports of Dr. Ricketts, the medical superintendent of their small-pox hospital ships. Writing in 1898, his words are clear, emphatic and succinct. He gives an admirable summary of the past history of small-pox in London, showing that the disease tended to move in cycles, that then (in 1898) the lowest point of a cycle had been reached, and that "in three years' time or earlier" an outbreak of small-pox was almost sure to occur. The comparatively small outbreak of 1893-94 had, he reminded them, "strained the resources of this hospital and proved that adequate accommodation for acute cases of small-pox did not exist. Considerations of this kind," he continued, "have made us with some anxiety on the fact that the projected Joyce Green Small-pox Hospital is yet uncommenced." In face of the warning that an outbreak might be anticipated in three years' time or earlier the hospital was not commenced until two years later. Even then it was not pushed, and it is only now—in 1903—approaching a condition of pre-
pareness. What has been the result? Dr. Ricketts' calculations were verified almost to the letter, and in the summer of 1901 small-pox cropped up in various parts of the Metropolis. By the autumn an outbreak was in full swing and cases began to pour in by dozens. Then the panic set in. The Board knew that public indignation would rise if they left small-pox cases unremoved, and they had only 250 acute and about 1,000 convalescent beds available. This time they seem to have had recourse to Dr. Ricketts for advice, and he recommended that the highest number of beds likely to be needed would be about 1,000 more. A temporary hospital of 300 beds was run up at Long Reach, and with this and the previous accommodation, although under great pressure, the epidemic was weathered. Despite Dr. Ricketts' recommendation to prepare 1,000 beds, they proceeded to put up two huge temporary hospitals—the Orchard Hospital of 800 beds and Lower Gore Farm Hospital of 600 beds, making with Long Reach Hospital 1,700 extra beds. The two former were completed just as the epidemic died out, and as a monument to their wisdom and foresight there now stand erected two enormous, flimsy, hurriedly-built hospitals containing no less than 1,400 beds that have never been used. Aye! and so far as one can see they never will be required for patients. Long before they are ever likely to be needed they will have fallen into decay, and their function will have disappeared, for Joyce Green—a permanent hospital of 2,000 beds—will then be available. They can never be used for other purposes, as they each lie in apposition to another small-pox hospital—the Orchard to Joyce Green and Gore Farm to Upper Gore Farm—and their use for other diseases would never be sanctioned. And what has all this muddle, confusion, and want of foresight cost? Lower Gore Farm £134,500; the Orchard, £69,000; and Long Reach, £57,000—all for buildings and fittings alone! Nothing is said about furniture and equipment, which doubtless cost a pretty figure in addition. A very low estimate would put the cost of the ratepayer at a quarter of a million, which for all the good it has done might as well have been thrown into the sea. And yet such is the ignorance of people in London about their own affairs that we have seen articles in our daily contemporaries extolling the Board's management of the epidemic! We ask our readers if we are not justified in calling public attention to one of the most glaring examples of extravagant Bumbledom that has ever been witnessed.

THE PROVISION OF DENTAL RELIEF.

It is a platitudinous at the present day to point out that the teeth are organs that the evolutionary processes at work on the civilised members of our species are tending to eliminate. To rescue the teeth and attempt to make them endurable is a Quixotic task, pre-doomed to failure. We have got to take the best of things as we find them and we find them very bad indeed. To meet an adult of middle age with a complete set of teeth in a sound condition is exceedingly uncommon, whilst it is hardly beyond the truth to say that every other patient one examines wears, or ought to wear, artificial teeth at the age of forty. The British Dental Association not long ago investigated the teeth of a large number of children in industrial schools, and they found that nearly 80 per cent. of them were the subject of caries. This would be approximately true of the young of most classes of the community, we take it. Now these facts being so, we must look the matter clearly in the face, and see what can be done. Dental caries, though rarely a cause of death, may be, and is, productive of a large amount of ill-health and much misery. Mal-digestion is initiated and perpetuated in multitudes of young and middle-aged people by inability to bite and chew their food; and the tenderness of the teeth and gums, produced by cavitation and periodontis, tends also to make the retention of the bolus in mouth too short for the completion of buccal digestion and of preparation for gastric digestion. The organism is wonderfully accommodative, but there is a breaking-point to the strain, and chronic indigestion, mal-nutrition, anaemia, constipation, and a dozen other troubles follow in the train of dental decay. Besides, the presence in any part of the body of inflammatory and suppurative conditions cannot but be conducive to ill-health, to say nothing of their obvious potentialities for evil in more direct ways. The social value of an enormous proportion of the population is distinctly discounted by the possession of bad teeth and their consequences. If the trouble is, then, as great as this, it should surely be tackled, and tackled energetically. But how? There's the rub. We have heard it is no good fighting against civilisation itself, of whose influences bad teeth are a by-product, and it is plain that one cannot extract the teeth of everybody born and give them artificial ones. American exaggeration culminated, we remember, in a serious proposal to perform appendectomy on every child as systematically as vaccination—an obvious reductio ad absurdum. Looking at the facts seriously, can nothing be done to preserve the teeth and provide for their treatment when diseased? The dental charities in London are quite inadequate to deal with a tithe of the work that ought to be done by such agencies, and the dental departments of the general hospitals—except Guy's—do not pretend systematically to treat teeth. And yet London is far better supplied with free dental institutions than any other large town. The difficulties, we take it, are two. First, the small importance that most people attach to their teeth, and their dread of the dental chair; and, secondly, the length of time that dental operations, other than extraction, take. Gratui-

tous 'or state-provided' dental treatment, if people availed themselves of it in anything like the degree that they should, would cost a sum that fairly staggered the imagination if reduced to figures. The dentists have, like ourselves, raised themselves from the level of artisans to that of professional experts, and, after a long and expensive education
and training, they justly look forward to a considerable competence during their working years, and very properly expect a fair fee for their long skilful operations. It is this very question of time and personal work in each individual case that would make the cost of state-provided dental treatment so enormous. When the guardians in England and Wales expend some eight to nine millions a year in the relief and maintenance of the poor, is it likely that they could be induced to spend another two or three millions (and it would cost all that) on dental treatment for those that could not afford a dentist's fee? The time is certainly not ripe for such proposals to be put forward with any chance of success, but we submit them for consideration in the hope that some concrete proposition may be evolved. In the meantime much might be done by the education of children in schools in the value and care of the teeth, and still more by submitting them to regular dental inspection. What we have always considered far better than flying to the dentist when the teeth give trouble is the regular, half-yearly visit to allow of any cavities being detected and treated at their inception. By this method we do not imagine that the teeth would be ultimately preserved to the race, but the comfort and health of the individual would be vastly enhanced. We would commend those who feel the importance of these questions to study the remarks made by Mr. Hern in the opening address at the Middlesex Hospital, and then to decide whether it is not worth while to press for some such scheme as he there suggests. For ourselves we will always warmly support any practical proposal that will raise the health and comfort of the poor, and we feel that the widespread provision of dental relief—either free or at low payments—is a very pressing need in this complex society of ours. But such a proposal must be practical—and practicable.

Notes on Current Topics.

The College of Surgeons and National Physique.

Our medical corporations have a happy knack of doing nothing to justify their existence, or of doing the wrong thing when stirred from their apathy. The Royal Colleges apparently think they have done their duty when they have taken the medical student's money for his examinations, and given him a diploma which he spends the rest of his life in grumbling at: He wants to be a doctor, and he is made a physician and surgeon. However, when the Government ask their august opinion the Olympians of Lincoln's Inn Fields condescend to be flattered, and—prepare a report. The question of the deterioration of our national physique is a momentous problem, and the continued operation of the causes now at work constitute one of the gravest national perils that face us. Under these circumstances it is interesting to note the answer which the College of Surgeons returns to the Home Secretary. After a number of analyses and criticisms of the memorandum submitted to them, they doubt whether there is need for a larger inquiry than is at present being conducted by a Committee. This, be it remembered, when every scrap of information on the subject of national physique is of vital importance, and when the College has only to say the word and a Royal Commission would be appointed! If no further facts were brought to light than are now known, the mere weight of a Royal Commission's report and recommendations would give authority and compel attention to what numbers of independent bodies, newspapers, and individuals are urging in season and out of season. We must write down this recommendation of the Royal College of Surgeons as hardly worthy of their traditions and their responsible position in regard to the community.

Sanitary Skirts.

The kilt and the skirt are articles of apparel which for many a long day have been subjected to serious criticism, and, as usually worn by their respective wearers, they have won much condemnation on so-called hygienic as well as athletic grounds. But both still persist, and are upheld by a conservative popular opinion. A mere Southern sanitary would not dare to define the deficiencies of a Scotsman's chief adornment, but the feminine skirt is ever with us, and its shortcomings, arising from structural superabundance, remain only too apparent. We understand that Parisian fashion favours a curtailment of the skirt, and we trust, in the interest of hygienic righteousness Englishwomen will recognise the reasonableness of discarding the trailing dust and dirt-collecting skirts so long fashionable in town life. Unless reform speedily follows we shall be compelled to publish results respecting the bacteriology of the skirt. We prefer, however, to appeal to the mind before hastening action by a resort to the fear of the microbe.

The Use of Salt Solution.

It is the universal distribution of sodium chloride and its occurrence as an essential ingredient of most organic tissues which have led to its employment for therapeutic purposes in the form of a 0.9 per cent. solution, familiarly known as "normal saline." The student early learns that this fluid makes the best medium in which to dissociate and examine fresh tissues, and when he comes into the wards he has many opportunities of seeing salt solution used as a remedy. The intravenous injection, or, failing that, the hypodermic introduction of normal saline has many times saved lives where death has been threatened from haemorrhage or shock, and in a paper read before the North Carolina Medical Society, Dr. G. P. Edwards believes that in the latter condition there is no other therapeutic agent that will bring about such quick and satisfactory results. In young infants and obese individuals in whom it is difficult to find the veins easily, injections of
the solution beneath the skin of the abdomen or infra-mammary region will prove nearly as efficacious as the intravenous method, though the beneficial action is somewhat slower in manifesting itself. In children who are also moribund from exhaustion consequent upon infantile diarrhœa, in whom the whole system is crying out for fluid, the hypodermic injection, or even the simple introduction of normal saline per rectum, is of great value, and will assist the flagging heart more than anything else. Its use has also been attended with striking, if temporary, result in cases of diabetic coma, and it has often enabled unconscious patients to rally enough to recognise their friends or transact important business. As in uremic poisoning, it would appear to act by diluting the toxins circulating in the blood and assisting in their elimination by the kidneys. Though disappointing in some cases, saline solution is one of the most valuable remedies in the hands of the physician.

The Diabetes Flour Company.

Our energetic contemporary Truth does well to expose one of the most disgraceful commercial methods ever adopted by any trading concern. The Diabetes Flour Company, of 15 and 16 St. Dunstan's Hill, E.C., in their desire to push their wares, have circularised all the chemists in the country offering them five shillings for every address sent them of people suffering from diabetes. Whether the stuff that this company purvey is, or is not, all that is claimed for it one need not now inquire. The point is that they deliberately try to bribe chemists to betray the confidence placed in them by their clients, a procedure as repugnant to every self-respecting pharmacist as it would be to every self-respecting medical man. It is to be hoped that by giving publicity to the methods employed by the Diabetes Flour Company medical men may think twice before recommending that particular article to patients. We have quite enough difficulty as it is in keeping our trades open and above board without importing discreditable tricks from other countries.

Blood as a Therapeutic Agent.

To the student of historical medicine few things are more interesting than the means adopted for the cure of disease in ancient or mediæval times. In strange contrast to the modern prescription, which is more or less rigidly confined to pharmaceutical products, the older remedies consisted very largely of organic materials derived from the animal or vegetable world. The various secretions and excretions of the body have all been found capable of some therapeutic application in disease, though it is doubtful if any one of them would be tolerated by patients in the present day. Some interesting facts relating to the supposed remedial effects of human blood are related by Dr. J. F. Payne, in Jams. One named Arnold de Villa Nova, who flourished in the middle of the thirteenth century, wrote a treatise entitled "De praestantia et virtutibus aquæ humanti sanguinis," in which the virtue of human blood in apoplexy, migraine, giddiness, and other morbid conditions is set forth, but the directions for use are left incomplete, it is supposed intentionally. Dr. Payne remarks that the practice of drinking fresh blood was known to the ancients, especially as a cure for epilepsy. Human blood was also employed medicinally in leprosy and other skin diseases. The belief in the possibility of extracting from the blood certain elements which possessed curative properties was largely shared by the older alchemists, to whom this study proved very fascinating. It was not, however, until a somewhat later period that the preparation of an elixir vita and the distillation of human blood came into vogue. Coming down to more modern times we learn that transfusion of blood is said to have been first performed in 1665. The possibility of being able to extract some substance of therapeutic value from the blood of animals is yet one which need not altogether be ignored.

The Borough Council Elections.

In the election of representatives to the Borough Councils in London, and, indeed, all over the country, the medical man had two clear duties to perform. He had first to exercise the privilege of good citizenship by recording his own vote, and he had secondly to bring the weight of his professional authority to bear on the votes of others. As the population increases and towns grow, the importance of hygiene becomes greater and greater, and though our sanitary code may be far from adequate an enormous amount may be accomplished by the diligent administration of its present provisions. For this reason we should strive by every means in our power to secure the return of men who have the great cause of the public health at heart. Neither the Progressive nor Moderate Party has the monopoly of such men, and political opinions and party bias should not be allowed to weigh in the support of candidates. In theory the manifesto of the Progressive party as it applies to the enforcement of the Public Health Acts is admirable, but is it not a little extravagant to claim support, as has been done in one quarter, on the ground that Progressive majorities have coincided with diminished death-rates? All sound and efficient administration will find its ultimate reflection in a reduction in the mortality returns, but a three-year period is far too short to produce any trustworthy data of this kind. The way of the reformer is hard, and the success of his efforts must be judged by centuries and decades, not by single years or even lustres. The man, be he Moderate or Progressive, who has no axe of his own to grind, but who is animated by a single-eyed devotion to the health of the people, is the man electors should have voted for.

Compensation for Insults.

Even the worm will turn, and there is no reason why the medical man should not occasionally do likewise. But to turn effectively all must turn together, and it is to be regretted that a certain lack of cohesion in our profession generally renders combined movements impossible. If we realise that people nowadays must have medical attend-
ance, we may, though shackled at times by humanitarian considerations, find ways to make them realise that even the medical man has his rights and privileges. An excellent example of what judicious combination can do has just been demonstrated at Westmeath. Certain members of the Board of Guardians at that place gave vent to some gratuitous and offensive remarks about the medical men of the district. The doctors, members of the Westmeath branch of the Irish Medical Association, have made an inarticulate but very effective reply. In spite of the affront they have not refused to attend the guardians, but have bound themselves to charge exceptional fees for attendance on them and their families. The surest way to reach most people is through their pockets, and it is to be hoped that the doctors will stick to their guns and to each other. A rapid climb-down and apology may then be anticipated on the part of the guardians. It is to be hoped that this original, but very practical, plan of the Westmeath medical men may form a precedent which others may follow in dealing with irresponsible and truculent critics.

Medical Officers to Education Authorities.
It was recently urged in the editorial columns of this Journal that medical officers should be specially appointed by all the new education authorities. The paramount importance of weeding out and dealing specially with weakly children was pointed out, and it was shown that this could only be accomplished successfully by following the advice of an expert. It is encouraging to find that out of a hundred large towns no less than forty-five have now adopted that course. In some of the larger, Manchester for example, an officer has been elected to devote the whole of his time to the work, whilst in some of the smaller the medical officer of health has been appointed to the post with a special salary. No doubt in small towns this latter is the more satisfactory method of dealing with the question, and there are many advantages in having a specialist in hygiene to supervise the health of the children. One cannot say, however, that the education committees take a wide view of the duties of such an officer, or surely they would not offer such miserable stipends for such important work. In Eastbourne, a town of nearly 50,000 inhabitants, and probably one of the richest in the country for its size, the salary conferred on the medical officer is £50 a year! Surely the health of the thousands of children under their care is worth more than wages of an unskilled labourer. The old adage magnus vectigal parsimonia may be drawn to too fine a point.

Mysterious Death at Dover.
The ways of coroners’ juries are proverbially so erratic as often to demand further revision by the police or the Home Office. An instance of that kind appears to have arisen at Dover, in connection with the death of a young woman. Deceased had been in the service of Mr. W. Newman, a veterinary surgeon, as housekeeper for seven weeks, during a month of which period she had been married. To all appearance she was in good health, when one morning she was found in a fainting condition, and shortly afterwards died. The post-mortem examination revealed nothing to account satisfactorily for death. The heart was slightly flabby and the stomach contained two or three ounces of fluid. The jury declined the offer of the Coroner to obtain an analysis of the contents of the stomach, and found a verdict of death from natural causes. This case is interesting as a type of the many perfunctory and unsatisfactory inquests that are daily conducted in the United Kingdom. The coroner is in the hands of his jury, inasmuch as he can do little more than protest against their finding, no matter how grotesque and inadequate that may be. In the Dover case the scientific evidence is clearly inadequate, and it is impossible for mortal man to say that deceased did not meet her death by poison administered either suicidally or homicidally. We do not for a moment suggest that anything of the kind has happened, but as things stand the possibility has certainly not been excluded. The Dover Coroner himself remarked, so it is reported, that the case above mentioned was most unusual and puzzling. A comment of that kind from an experienced Coroner suggests the need of further inquiry by the police and the Home Office, and it is to be hoped, in the public interest, that such further official inquiry may be forthcoming.

Contending Views as to the Causation of Phthisis.

Since Koch’s famous utterance at the Congress on Tuberculosis two years ago, there has been nothing said in relation to the subject of interest at all equal to Professor von Behring’s recent address at Cassel. Given with far more sobriety and far less seeking for sensation than Koch’s address, it is, as regards its practical bearings on the prevention of tuberculosis, of at least equal importance. The doctrine of the former, if accepted, goes to stop any care as to the ingestion of tuberculous milk, while that of the latter tends toward making us disregard any dangers at present believed to spring from the inhalation of tubercle bacilli. Behring’s thesis, indeed, is that practically all adults are tuberculous; between the ages of eighteen and thirty, the percentage of tuberculous infections is 96, the figures being got by post-mortem examination in cases of death from all causes; while in persons over thirty, all bodies are said to show tuberculous lesions. Parallel with this is the observation of Tracey, that from 60 to 70 per cent. of soldiers in two Austrian regiments gave a positive tuberculin reaction. If it be, then, that we are all tuberculous what is meant by the development of phthisis? According to Behring, the tuberculous foci, which may remain quiescent for years, suddenly become active, owing to the subject adopting a mode of life suitable for such development. The original infection he believes to enter by the digestive organs in infancy; or secondary infection is necessary to bring about the appearance of phthisis. It is, of course,
far too early to express an opinion on these startling arguments, as they will have to undergo thorough testing before they are either received or rejected. It is interesting to note that Behring is strongly opposed to Koch's views on the relations of bovine and human tuberculosis.

**Epidemic Cerebro-Spinal Meningitis.**

From time to time there have occurred in various parts of the Continent, Great Britain, and North America epidemics of an acute febrile disease accompanied by specific nervous symptoms and very often by a rash, generally of an herpetic character. This affection formerly bore the name of cerebro-spinal fever, but from the researches of Weichselbaum, who obtained a special organism, the *Diplococcus intracellularis meningitidis*, in the exudation, the name of cerebro-spinal meningitis is more comprehensive. A curious epidemic of an illness bearing a very close resemblance to this has just been investigated by Dr. Reginald Farrar and reported in a memorandum to the Local Government Board. The outbreak occurred in the village of Criftins, which is situated in the Ellesmere Rural District and about five miles from the town of Oswestry, in the month of May last. It is computed that fifty children attending the Criftins school were attacked by illness, but from further inquiries Dr. Farrar concluded that the total number affected was about eighty. The features common to nearly all the cases were weakness, acute febrile disturbance of sudden onset, severe headaches, vomiting and diarrhea. In many cases there was delirium, aching in the spine, and in five or six there was herpes labialis. Two deaths occurred, which were both certified by Dr. Bulstrode, of Ellesmere, whose notes are appended in the Report, as due to "acute meningitis" (not considered to be tuberculous). No satisfactory origin could be ascribed for the outbreak, but it is stated that a procession of children was organised to view the body of the first child, a boy of seven, who died of the disease. In Oswestry, a town of about 10,000 inhabitants, five or six cases of a similar nature occurred, and one of these was confidently diagnosed by Dr. Beresford, the medical officer of health for the Oswestry Urban District, as being epidemic cerebro-spinal meningitis. The possibilities of the disease being a severe type of influenza are discussed, but the evidence has many points in favour of the diagnosis of epidemic cerebro-spinal meningitis. Had it been possible to secure cultures of the fluid obtained by lumbar puncture the suspicion might, perhaps, have been confirmed.

**Case of Rag-Sorters' Anthrax.**

An interesting case of death from anthrax infection has recently been investigated at Dewsbury by a coroner's court, at which the Home Office was represented by no less than five prominent officials. From the evidence, it appeared that the deceased, a woman, forty-one years of age, met with her death as the result of anthrax. She contracted the disease apparently in the course of her occupation as a rag-sorter, though there was no evidence to show that any of the particular rags sorted by her had been previously in contact with sheep or cattle. The dust from the rags was burnt every week. The owner of the place had failed to comply with the requirements of the law, and the local sanitary inspector actually did not know of the existence of these rag-sorting premises. The jury, however, returned a verdict of death from anthrax, without attributing wilful neglect to the owner. Dr. Legge, Government Medical Inspector, remarked that during the last five years notifications had been received at the Home Office of 205 cases of anthrax, mainly in factories and workshops, out of which 47 deaths had occurred. The case before the jury was the only one reported in the industry of rag-sorting. Sixty of the cases had occurred in the woollen industry, 60 in skins, over 30 in horsehair, and the rest in other industries, mostly connected with wool. The disease was unknown among rag-sorters. In Austria, between 1885 and 1895, there were 70 cases. They were known as true wool-sorters' type, internal. It was external in the case of the deceased woman. He thought that the disinfecting of the warehouses played an important part in the prevention of the disease. In cases of anthrax early treatment was most important.

**The Physician as Patient.**

It is often said that a medical practitioner makes the worst of patients. To some extent this may be true, but there are usually mitigating circumstances making a recommendation to mercy reasonable. But we are not so much concerned with the attitude of the sick physician, as desirous of insisting on the desirability of a practitioner knowing from personal experience something of the irksomeness and discomfort, or, on the other hand, attractiveness and comfort arising from measures or methods ordered for therapeutic purposes. In these days of "open-air" treatment, how many physicians have actually undertaken a week's residence and undergone routine treatment in a sanatorium? Few practitioners have experienced the sensations arising from massage, high frequency currents, and various other forms of mechanical and electrical treatment. Even in the course of their travels it is remarkable how few medical men avail themselves of opportunities to test the action of various mineral waters, or test for themselves the different baths they are accustomed to recommend to their patients. It is not so much a question of "Physician, heal thyself," as "Doctor, feel for thy patient." A little more practical experience self-inflicted would do much to lighten the weariness of many a real sufferer.
A New Intestinal Bobbin.

The number of bobbins, buttons, and such-like contrivances for uniting the divided ends of intestines that have been devised from time to time are evidence that no completely satisfactory form of this necessary appliance has been as yet designed. A new variety of bobbin has been recently described by the designer, Dr. MacLennan, of Glasgow, in a contemporary, and appears to offer certain advantages, particularly in point of rapidity of execution, over the other forms on the market. This bobbin, which is made of decalcified bone, is somewhat in the form of a truncated cone. At the larger end it is surrounded by two shallow grooves, and at the smaller end by one deep groove. The bobbin is introduced, small end first, into the proximal end of the divided intestine, and the latter is fixed to it by a single encircling ligature which lies in the shallow groove nearest the large end. A rubber ring, resembling an umbrella ring, is then slipped on over the gut, and lies in the same groove as the encircling ligature. The proximal end of the intestine with the contained bobbin is then inserted into the distal end, far enough for the latter to cover the rubber ring and the second shallow groove, into which the distal end is fixed with a second tightly applied ligature. The rubber ring is then pushed upwards along the bobbin until it slips into the groove at the smaller end, and in this process carries with it a double layer of the distal end of the gut. As soon as it has snugly fitted into this groove, the junction of the intestine is complete. Union takes place between the proximal and distal ends beneath the ring, and the portions of ligatured gut at the distal side of the ring come away. The operation is not easy to describe in a few words, but as portrayed by Dr. MacLennan, appears to be most simple. It has been put into practice in the case of dogs with successful results.

Sanitary Officers in the Army.

The degree of appreciation which sanitary officers meet with in the Army does not appear to be materially greater than that enjoyed by their civil confrères. A writer in a recent issue of the Broad Arrow draws attention to this fact, in view of the recommendation recently made by the Advisory Board that sanitary officers should be restored. Even so high an authority as the present Commander-in-Chief, an authority, moreover, who cannot be accused of any prejudice against the medical profession, takes no pains to hide the fact that he considers sanitary officers a useless appendage to an army in the field. In his "Soldier’s Pocket Book," he writes: "The sanitary officer is a creation of recent years, and as a rule is a very useless functionary. In numerous campaigns I can conscientiously state that I have never known him make any useful suggestion, whereas I have known him make several silly ones." It is quite possible that sanitary officers, like many other officers, may occasionally tend to ride their speciality to death, as in the case Lord Roberts records of the sanitary officer who wanted him to delay an army on the march while a town was being drained. On the other hand, how many sanitary disasters have resulted during the South African campaign which might have been prevented if the Army had possessed skilled sanitary advisers? It is not, however, unnecessary to point out that it is useless to expect skilled advice and expert opinion which will be of value from a sanitary officer when his reports are liable to be "criticised and reviewed" by any layman who happens to be Under Secretary to Government, and who is empowered to expunge any portion of such report if it should be disapproved by any department.

An Educational Municipal Sanatorium.

In spite of the optimists pulmonary tuberculosis is not likely to disappear from the long list of troubles which overpower the human. At the present time, indeed, it is impossible to provide adequate accommodation for the immense number of consumptives clamouring for relief. The demands of the situation have extended far beyond the possibilities of philanthropically directed assistance. Sufficient help can only come from municipal and state intervention. At present, though, it has not sufficiently crystallised to warrant general action; and much of present action is avowedly experimental. One of the most interesting and important of these experiments is being carried out by Dr. Arthur Newsholme, the distinguished medical officer of health for Brighton. The Borough Fever Hospital, which is excellently situated on the high ground behind the town, is being used in part as a sanatorium for consumptives where phthisical residents within the borough may be received for the period of a month and instructed in the principles of a hygienic life. Efficient open-air treatment is provided so that both from the public as well as the personal standpoint much good should accrue. Dr. Newsholme’s important experiment should be carefully watched. It is apparently an important step in the right direction.

Trees and Coal-Tips.

Travellers in our coal-mining districts know something of the profound mental depression aroused by the unsightliness wrought by that burrowing animal man. It is often contended that a considerable portion of our national characteristics is dependent on climatic conditions. This may well be, but it is not always allowed that the occupations more or less peculiar to certain districts have much moulding influence on the morals of the dwellers, and yet this is undoubtedly so. The psychological aspects of residence might well be the subject for scientific investigation. All that makes for the beautifying of a neighbourhood is to be considered as helpful in the hygienic development of those destined to live therein. We are pleased, therefore, to find that the Midland Reafforestation Association is about to take steps to make beautiful the waste
places of our pit-tips and spoil banks. It is estimated that quite 30,000 acres may ultimately be planted. We have heard much concerning garden cities. We are now to have our unsightly coal districts turned into sylvan resorts. All this when accomplished will prove an immense boon to the physical and mental health of the people.

Hygiene—and the Umbrella.

PERPETUAL rain has necessitated a persistent acquaintance with the umbrella. This instrument of protection deserves to be had in everlasting remembrance, but honesty requires that its shortcomings be duly acknowledged. An open umbrella is like an industrious labourer, but a closed and wet shelter is oftentimes a nuisance and danger. It is surprising how meagre is the accommodation provided in many churches and other places where the human of necessity has to congregate, for the ubiquitous umbrella. Damp, dirt, disorder are the results of a rain-soaked "gamp," and in the interests of sanitary order and hygienic rectitude it is most desirable that precautions should be taken to diminish the disadvantages flowing from a hard-worked umbrella. Prophylaxis demands that a protector of health shall not be permitted power to derange anything making for comfort and well-being. And the moral of all this is clear. An umbrella at rest requires a suitable resting place.

Dinner and Presentation to Professor Cunningham.

A MOVEMENT is on foot in Dublin to mark the severance from that city of Professor Cunningham, formerly Professor of Anatomy in the School of Physic, Trinity College. We understand that his numerous friends and past pupils have decided to entertain him at dinner on November 21st, and the arrangements which have been made with that end have so far progressed most satisfactorily. It is also the intention of the past and present pupils to avail themselves of the opportunity afforded by the dinner to present Professor Cunningham with a piece of plate of Irish design in the shape of a large "Methyr" cup. Professor Cunningham's relations with his pupils were in the past so cordial a character that it is not surprising to learn that the presentation has been largely subscribed to.

The Mastership of the Rotunda Hospital.

The septennial election to the Mastership of the celebrated Rotunda Hospital takes place on Friday next, and much interest attaches itself to it. The Governors are limited in their choice to the former Assistants of the Hospital, from amongst whose ranks several distinguished candidates have offered themselves, and among them the Governors will have no difficulty in obtaining a suitable Master: The Mastership of the Rotunda Hospital is a most responsible position, and does not perhaps possess an exact counterpart elsewhere in the United Kingdom. It has a worldwide reputation, and one which at the present time of great scientific activity in the various medical educational centres it is no easy matter to maintain. There are now many more gynecological and obstetrical teaching centres to attract students than there were a few years ago, and if the Rotunda Hospital is to compete satisfactorily with them it needs a most energetic and capable Master. The decision of the Board will be awaited with much interest in medical circles.

We hear that an anonymous donor has presented 12½ acres for the new King's College Hospital in South London. An appeal is being made for £300,000 to build and equip the fresh establishment.

PERSONAL.

SIR WILLIAM TURNER THISTLETON DYER, K.C.M.G., C.I.E., M.A., F.R.S., has been elected first President of the newly-founded Therapeutic Society.

DR. JOSEPH GRIFFITHS SWAYNE, late of Clifton, author of the popular "Obstetric Aphorisms," has left real and personal estate of the value of £43,986.

It is announced that the committee of the National Physical Laboratory has appointed Mr. W. A. Casparis, B.Sc., Ph.D., to the post of junior assistant in the chemical department.

VISCOUNTESS MOUNTGARRET opened at Leeds last week the new Hospital for Women and Children, the Lord Mayor (Mr. John Ward) being present. The buildings afford accommodation for forty-eight beds.

THE Harveian Lectures will be delivered this year on November 5th, 12th, and 19th by Dr. D. B. Lees, at the Stafford Rooms, London, W. The subject selected is "The Treatment of Some Acute Vascular Inflammations."

THE Earl of Derby (the Chancellor) and the senate have issued invitations for the inaugural ceremony of the new University of Liverpool, which will take place at St. George's Hall in the afternoon of Saturday, November 7th. Academic costume will be worn on the occasion.

THE Hughes Jackson Lecture of the Neurological Society of the United Kingdom will be delivered by Sir William Broadbent, Bart., M.D., F.R.S., at 11 Chandos Street, to-morrow, Thursday, November 5th, at 9 p.m. The subject will be "Hughes Jackson as Pioneer in Nervous Physiology and Pathology."

DR. ALFRED S. GUBB, who for many years past has occupied the post of the London editor of THE MEDICAL PRESS AND CIRCULAR, has relinquished that post and his London practice, and will in future practise alternately at Algiers and Aix-les-Bains. Dr. Gubb holds the M.D. of the Paris University, as well as an English medical qualification.

We learn that Sir William Taylor, K.C.B., Director-General of the Army Medical Service, will preside at a dinner of the Glasgow University Club, London, to be held on Thursday, November 26th, in the Trocadero Restaurant. Particulars may be obtained from Mr. James Dodds, Dover House, Whitehall, or from Dr. C. O. Hawthorne, 28 Weymouth Street, W.
Special Correspondence.

SCOTLAND.

Friction at the Dundee Asylum.—From reports which have appeared in the daily press it would seem that there is present considerable friction between the medical superintendent and the Lunacy Board, and that a committee of the Board has recently had to inquire into several matters affecting the internal management of the asylum. The friction seems to centre chiefly with three matters: First, the reinstatement by the superintendent of an attendant who had been dismissed by the senior assistant physician during the medical superintendent's absence. Dr. Tuach, the assistant physician, alleged that the attendant had broken the rules of the institution by absenting himself for two days without leave, and that Dr. Rorie, the superintendent, reinstated him without previous consultation with Dr. Tuach. The committee regarded this as an error of judgment which would be most detrimental to the maintenance of discipline, recommended that the attendant be discharged. Second, the resignation of the matron and senior assistant physician were considered. The latter complained that his efforts to secure proper treatment of the patients were not seconded by Dr. Rorie, that he himself had been treated with injustice and dishonesty, and that Dr. Rorie made the head attendant his medium of information regarding the patients. The committee found that Dr. Rorie ought to have instituted a strict inquiry into an alleged disturbance near the dormitories by the patients, at an hour when the patients ought to have been asleep. They are of opinion that Dr. Rorie's relations with his assistants are unsatisfactory, and that he be enjoined to treat them with due courtesy. The third matter related to the attendance of a patient on September 24th. On September 15th, Dr. Shepherd was informed by a night attendant that he had found a patient much bruised about the chest, and on examination the doctor found that the bruises were about two days old. Failing to ascertain the cause of these, he reported to Dr. Tuach, who reported to Dr. Rorie. In Dr. Rorie's evidence on this case he quoted a passage from his diary of September 17th: 'Found bruised in the back room, and can't get any information.' On September 17th, the patient was discharged. On September 19th, Dr. McMahon informed Dr. Tuach that he had been told that patients had been occasionally tied in bed. Afterwards denied point by Mitchell and Chalmers. Instructed by the matron of the Lunacy Department to communicate with the Procurator-Fiscal, who held an investigation. The committee examined the assistant physicians and the attendants in reference to this case, and were satisfied that the former promptly made every effort to ascertain the cause of the patient's injuries. At the post-mortem examination the cause of death was found to be double pleurisy, with fracture of right ribs. The committee found that the patient was very restless, and that on several occasions he fell out of bed: the patient had experienced great difficulty in obtaining information from the attendants, none of whom gave a clear account of how the injuries were sustained. They were not satisfied that these were actually due to his falling out of bed, nor were they satisfied that strapping down was not at times resorted to. Dr. Rorie's examination seems to have been a very inadequate one, and the committee regard him as having trivialized with a very serious matter. When the report, of which the preceding is a summary, came up before the District Lunacy Board, a letter from Dr. Rorie was read, stating that in view of the extraordinary nature of the investigation committee's report, and the fact that it came upon it in the newspapers he had never seen that report, he considered it advisable to ask for a full and independent investigation of the whole matter by the Committee of Management, and the appointment of the secretary of the General Board accordingly. By eleven votes to eight the report was agreed to, this involving the dismissal of the reinstated attendant, the enjoining upon Dr. Rorie of courtesy to subordinates, and the remitting to the General Board the question of the death of the patient. In the discussion it was repeatedly stated that chaos existed, and had done so for many years, at the asylum, and that the attendant's conduct of drunkenness and brutality on the part of some of the attendants. That there should be even prima facie evidence of such a state of matters as the report suggests at any asylum is nothing short of deplorable; if things actually as reported constitute a very grave scandal, and it earnestly be hoped that a thorough independent inquiry will be at once instituted and the offenders promptly and decisively dealt with.

THE RANGOON LYING-IN HOSPITAL.—A PROTEST.

To the Editor of The Medical Press and Circular.

SIR,—We have in Rangoon a Lying-in Hospital. It was built with money given by the general public for that purpose. It consists of one building containing on the two lower floors six rooms for about thirty women, and thirty nursery cases, with an anteroom on the third floor. There is within a mile of the lying-in hospital a large general hospital with some 450 beds. This institution is amply provided with funds and accommodation for the treatment of general medical and surgical cases, male and female, and the performance of every description of surgical operation.

Under the orders of the late Lieutenant-Governor, Sir...
Obituary.

Dr. William Dobbin, of Banbridge, in his sixty-first year, at a private hospital in Belfast. Dr. Dobbin was educated in the last-mentioned town, where he took the B.A., and M.A. degrees with high honours, and in 1867 that of M.D. In 1886 he took the Fellowship qualification of the Royal College of Surgeons of Ireland. He spent his professional life at Banbridge, and was known widely throughout Ulster, where he had a large circle of friends. He leaves behind a widow and a family of one daughter and two sons, of whom one is a M.B. of Edinburgh University.

Obituary.

Dr. Robert John Gorden.

We regret to announce the death of Dr. Robert John Gorden at Croyoach, whether he had retired for several years past on account of failure of eyesight. He was a brilliant student of the University of London, and he graduated with honours as M.B. and C.M. in 1872. After studying on the Continent, he settled in Aberdeen, and was appointed assistant-surgeon to the hospital in 1880 and full surgeon in 1890. He held many important social and medical posts during a career that has been prematurely ended. His retirement from the hospital in 1900 was the occasion of a warm testimony to his many acquisitions, both professional and social. His loss will be felt by a wide circle of friends.

Lieut.-Col. R. V. Ash, A.M.S.

We regret to announce the death of Surgeon-Lieutenant-Colonel Robert Vacy Ash, late Army Medical Staff, at Morecambe, aged fifty-eight years. He entered the service in 1871, surgeon-major in 1883, and retired as surgeon-lieutenant-colonel in 1891. He served in the Zulu War of 1879, in the Egyptian War of 1882, and was present at the battle of Tel-el-Kebir. He also took part with the Burmese Expedition in 1886-87. He was several times mentioned in despatches, and received various medals and orders.

Medico-Legal Society.

At the last meeting of the above society the following were elected officers: Sir William J. McCullagh, President; Sir William J. Minto, Vice-Presidents: Mr. R. B. Hopwood, K.C., Mr. A. J. Pepper, Dr. A. Bostock Hill, and Prof. M. Hay. Council: Dr. Garson, Dr. C. O. Hawthorne, Dr. T. N. Kelvynack, Dr. Harvey Littlejohn, Dr. G. D. Dandiford Thomas, Dr. F. J. Smith, Dr. W. McCallin, Dr. F. J. Wethered, and Dr. W. Wynn Westcott. Treasurer: Mr. John Troubridge. Secretary: Mr. R. Henslowe-Welington. Assistant Secretary: Dr. S. B. Atkinson.
DR. LUNY, in the present issue of Travel, states that a Russian topographer named Passtoukhoff finds tea taken almost boiling a satisfactory agent in combating mountain sickness.

***

Medical officers in the casualty departments of our city hospitals will be interested in Mr. C. R. Sherlock's attractively illustrated paper on "Risking Life for Entertainment," in the current number of the Cosmopolitan.

***

Dr. Louis W. Samson, in the current number of Dr. Charles F. Hartford's interesting quarterly, Climate, contains his valuable studies of the chief disease scourges of the tropics in their relation to the development of Greater Britain.

Mr. Edward Harper Parker, Professor of Chinese at the Owens College, Manchester, in his new work, "China: Past and Present," (Chapman and Hall) has an interesting section on Chinese medicine and the prevalence of leprosy in China.

***

Professors Ludwig Hektor and E. O. Jordan, of the University of Chicago, are editing a new periodical to be called the Journal of Infectious Diseases, for which Mr. and Mrs. S. A. Jordan McCormick have supplied an endowment of $125,000 dollars.

***

The Association for the Oral Instruction of the Deaf and Dumb, Fitzroy Square, London, have issued the Report of their Training College for Teachers and School for Children, which is a record of good work accomplished in the interests of the deaf members of the community.

***

Mr. Richard Whitting's new novel, "The Yellow Van" (Hutchinson and Co.), will prove of interest to medical men, containing as it does a pathetic picture of London hospital life, and dealing with sociological problems of the greatest importance to the development of the nation.

***

Dr. Foussard, Physician at Plombières-les-Bains, has written a brochure on "Muco-Membranous Colitus" (London: Bailliere, Tindall and Cox, 1903, Price 1s. net), in which the symptomatology of this obscure affection is well presented and practical suggestions made as to its treatment.

***

The recently issued fasciculus of the new Sydenham Society's Atlas contains a very valuable series of coloured plates which beautifully illustrate the lesions in tuberculosis as seen by the young generation, and amongst these illustrations are two interesting ones provided by Dr. Kelyanack from cases in which conspicuous pigmentation arose from the drinking of arsenical beer.

The current issue of the Manchester Medical Student's Gazette forms a special medical school number, and contains an interesting history of past medical matters in Cottonopolis and a description of its present facilities for medical study, the Gazette is well illustrated and should prove attractive to all concerned in the evolution of Manchester's Medical School.

Last year the Medico-Psychological Association of Great Britain and Ireland issued the report of its Tuberculosis Committee, in which important evidence was given respecting the prevalence of phthisis in our public asylums and valuable suggestions made as to the steps to be taken. Unfortunately, however, many of the statistics were found to be incorrect. The Council has very wisely issued "A Revision of the Statistics presented by the Committee on Tuberculosis," which has been carefully prepared by Dr. T. A. Chapman, late Medical Superintendent of Hereford City and County Asylum. The report should be carefully studied by all alienists and those responsible for asylum management.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list:

BAULIERS, TINDALL & COX (London).

HANDBOOK OF DISSECTING OF THE EAR. By Richard Laid, F.R.C.S. 54 Illustrations and three Coloured Plates. Pp. 10s. 6d. 18mo. Price 6s. 6d.

BERNSA & SONS, LTD. (London).

CARELL & CO., LTD. (London).

CHAPMAN & HALL, LTD. (London).

A. E. CHECHLIA (London).

WILLIAM P. CLAY (Edinburgh).

GEORGE GILL & SONS, LTD. (London).

H. K. LEWIS (London).

LONDON, GREEN & CO. (London).

CANCER. By J. A. Moxon (Edinburgh).

OLIVER & BORN (Edinburgh).

REMBAY, LTD. (London).

W. G. ATTICHEON BOTTROM (Edinburgh).
Contributions to the Physiology of Digestion and to Dietetics. By W. G. Atticheron Robertson, M.D., etc.

W. B. SAUNDERS & CO. (London).

A TEXT-BOOK OF OBSTETRICS. By J. Clarence Webster, M.D., Edin., F.R.C.P.E., etc. Illustrated. Pp. 833. Price 21s. 6d.

TUB "PHARMACISTS," LTD. (London).

JOHN WARD & CO. (Bristol).
Essentials of Surgical Diagnosis with Illustrative Cases. By E. Haastmore Bishop, F.R.C.S., and an Appendix on Examination of Blood, etc., by C. H. Melland, M.D., M.R.C.S. Pp. 297. Price 5s. 6d.

The King's Sanatorium.

His Majesty the King yesterday laid the foundation stone of the King Edward VII. Sanatorium at Midhurst. Elaborate preparations had been made to give a grandiose and characterful color to the proceedings. The King travelled by special train from Waterlooville and was received at Haslemere Station by Viscount Midleton, Lord Lieutenant of Surrey, the Sheriff and the Under Sheriff, and Sir William Broadbelt, Bart., M.P., Chairman of the King's Advisory Committee. A distinguished company of visitors left Victoria by special train at nine o'clock, reaching Midhurst a little before eleven o'clock, and were conveyed in carriages to the site of the sanatorium. Sir Wm. Brackets read a brief address, and the actual ceremony was short, simple, but impressive. Luncheon was served in booths erected on the ground. The King's Sanatorium has been founded under most auspicious circumstances, and it may well be that its future will prove one of inestimable usefulness to the consumptive poor of these isles.

Enteric Fever Outbreak at Methyr.

Dr. Thomas, the medical officer, reported to the health committee of the Methyr Urban District Council on Wednesday last that sixty-three cases of enteric fever had been notified during the four weeks ended October 10th.

Anti-Vivisection in Austria.

It is reported that the Austrian Anti-Vivisection League has prevailed on a group of deputy's to bring up a motion in the Reichsrath tending to make vivisection in every case illegal. The committee of the Lower Austrian Landtag has conveyed to Professor Chrboak orally an order to remove all animals kept for experimental purposes. The Professor is said to have retorted that he would take his orders from the Ministry of the Interior only.

Cork Medical and Surgical Society.

The annual dinner of the Cork Medical and Surgical Society was held on October 24th. The chair was occupied by the president, Dr. J. Cotter. After the usual loyal toast had been duly honoured, Professor J. J. Charles and Professor W. E. A. Cummins replied to that of the "Cork Medical School." Professor Charles referred to the numerous important posts occupied by past students of the Queen's College and the desirability of maintaining the medical school at its present high standard. Our guests were responded to by Sir Abraham Sutton and Mr. O. C. Cowan. The former in his speech referred to the rumoured proposed settlement of the University question, and commented on the loss it would be to the present normal school if the medical school were swept away as the result of any political manoeuvring. Mr. Cowan (Local Government Board) expressed his admiration for the medical profession and his sympathy with the grievances of the Poor-law medical officers, but pointed out that unjust odium had attached to the Local Government Board, as its action is necessarily limited by the amount of the funds received from the Treasury.

Memorial to the late Mr. C. W. Chubb.

On October 17th the Archdeacon of Bodmin dedicated a stained-glass window in the chancel of St. James's Church, Torpoint, as a memorial to the late Mr. Charles William Chubb, M.R.C.S., Eng., L.S.A., who was churchwarden for about twenty years. The Archdeacon, who also preached, alluded to the unselfish and genuine life of the deceased and to his devotion to suffering humanity.

Birmingham University and Vivisection.

The National Anti-Vivisection Society recently held a meeting at Birmingham to protest against a licence being granted to the Birmingham University to conduct a laboratory for vivisectional purposes. The following resolution was urged:—"That the Senate of the University of Birmingham is unable to see how the application of the University of Birmingham for a licence to promote scientific research. I think it is a cruel libel upon men like Sir Oliver Lodge, Dr. Windle, and others to attribute to them the possibility of any act of cruelty.
I shall be obliged if you will read this letter to the meeting which you propose to hold—"I, Madam, to that end." Mr. R. Somerville Wood moved a resolution appealing to the Home Secretary not to grant the licence, and this was seconded by Dr. G. H. Brand, and carried.

A TUBERCULOUS patient died under an operation last week at the Southwark Infirmary. The anesthetic used was chloroform and ether mixture. The patient was in a feeble condition, and after death the heart was found to be extensively degenerated.

PASS LISTS.

The Royal University of Ireland.

The Examiners have recommended that the following candidates be adjudged to have passed the M.B., B.Ch., B.A.O., and M.D. degrees examinations respectively:—

The following candidates have passed the Third Examination in Medicine:—

The Royal College of Surgeons, Edinburgh, Royal College of Surgeons, Dublin, and Faculty of Physicians and Surgeons, Glasgow.

This quarterly examinations of the above Board, held in Edinburgh, were concluded on the 28th ult., with the following results:—

First Examination (Four Years' Course).—Daniel Joseph O'Connell passed the examination.

First Examination (Five Years' Course).—Of twenty-five candidates entered the following seven passed the examination: Henry Ronald Leonard, Oliver David Gunasekara, Harold Hilton Bradley, John Patrick Sinnamon, Timothy John Vaughan, Robert McConnell Blair, and William James Valentine Curtin; and one passed in physics, three in elementary biology, and one in chemistry.

Second Examination (Four Years' Course).—Of four candidates entered the following two passed the examination: Frederick Francis Middleweek and James Ringland Lawther; and one passed in anatomy.

Second Examination (Five Years' Course).—Of thirty candidates entered the following fifteen passed the examination: William Murphy, Robert Johnstone Crichton, Charles Henry Arthurdon, Arthur Randolph Fulton Douglas, James Silvester Morris, Angus Cameron Mackay, John Ferguson, Maine O'Flaherty, John Hugh Simpson, Duncombe Steele Perkins, Muriel Mulrain, Bernard William Dakers, James Stirling Macdonald, Thomas Main Reid Waddell, William Hanna Clarke, and William Alexander Huston; and one passed in anatomy and two in physiology.

Third Examination (Five Years' Course).—Of twenty-nine candidates entered the following sixteen passed the examination: Alan Cunliffe Vidal, John William Low, Lester Ernley, Edward John Alexander, William Montgomery Johnston, Denison Cecil Woods, James Taylor, William Dick, Edward Ernest Murphy, Edward Francis Nyhan, Michael Philip Desmond, Charles John Bhatena, Gunamal Santdoss Thadani, James Dow Kennedy, Daniel Michael Donovan, and Capel Geary Dyer; and two passed in materia medica.

Conjoint Examinations in Ireland.

The following candidates have passed the Second Professional Examination (new and old regulations) as undernoted:—

The following candidates have passed the third professional examination as undernoted:—

Indisputably omitted from the list of second professional examination, W. S. Carter.

Cambridge is now officially declared to be free from small-pox. For four months the town suffered under the epidemic, and all through there have been 146 cases. An extraordinary feature of the epidemic was that it was not at first correctly diagnosed, and the disease, being treated as chicken-pox, spread rapidly. Fifteen deaths have occurred.
NOTICES TO CORRESPONDENTS.

Nov. 4, 1901.

Letters to Correspondents, Short Letters, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature at initial, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by adhering to this rule.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Authors.—Reprints of articles appearing in this Journal can be had at a reduction. Authors giving notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Dr. M. S.—We do not think the rule applies, but will make further inquiries and let you know.

DISEASES OF WOMEN DUE TO CLOTHING.

To the Editor of The Medical Press and Circular.

Sir,—I see in the report appearing in your issue for Oct. 4th, 1900, page 454, would be best answered by being referred to your issue for June 26th, for an article on Chlorosis, page 288.

I am, Sir, your faithfully, W. WILLIAMS.

BLOOMSBURY.—Your question is not particularly definite, but we think Ingrid M. Peiffer's article, appearing on an eighth edition of which is now before us, would answer your first requirement. The second would probably be met in Woodrow's "Comparative Ootoxinology." SUGIING FOR FEES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your issue of Oct. 19th, page 404, you state in the 'Correspondent' that "Members and Fellows of the Royal College of Physicians sign an undertaking not to sue for fees." This is true with respect to Fellows, but not so with Members; the latter have a perfect legal right to sue for fees for professional attendance, and have done so repeatedly to my knowledge, with success.

The by-laws of the Royal College of Physicians is only restrictive as to Fellows.—I am, Sir, yours truly, GEORGE BATEMAN.

SIRTON MAJOR H. (Malta).—With much pleasure.

R.B.R.A.—You have yet to see, perhaps, the best practical book on the subject with which we are acquainted is "Anesthetic," by Dr. Blundell, in the Medical Monograph Series issued by Bailliere & Co. You should lose no opportunity that offers itself of administering an anaesthetic, under skilled supervision, as it is only in that way that the necessary experience and confidence can be gained.

BARE FACED ASPECTICISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—I venture to call your attention to in its last issue some lines on the "Aspetic Nurse's Nest." Perhaps you would kindly insert the following:—

A surgeon who shaved off his beard In the midst of his colleagues appeared When asked, he said, When the reason he gave (d) The surgeon named Susan and Charles Should, of course, have the greatest success, And those in hospital. The Bacillus in beard, The bare faced they only caress. Yours, &c., A. D.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 4TH.

Ophthalmic Society of London (20 Hanover Square, W.),—8 p.m. Specimens will be shown by Dr. Leeks, Mrs. Stanley Boyd, and others. Short Communications—Dr. W. H. Broo—On Ovarian Carcinoma. Dr. E. M. G. Scott—On the Way between the Layers of the Mesoderm, both Broad Ligaments, and the Mesosomnum.—Dr. E. A. Barton—Foot-Care. Paper.—Dr. G. J. Maguire—Acute Conagous Pneumonia in the Newly-born.

Medical Graduates' College and Polyclinic (22 Cheapside, W.C.)—4 p.m. Mr. J. S. Clingie.—(Surgical). 3:15 p.m. Mr. C. B. Keeley.—Unreduced Diabietics.

THURSDAY, NOVEMBER 5TH.

Hartian Society of London (Stafford Rooms, Tichborne Street, Edgware Road, W.),—3.20 p.m. Dr. D. B. Lees.—The Treatment of Tumour of the Spinal Cord (320 London Society). Paper.—Harvian Lectures: Royal Society (20 Hanover Square, W.),—8.30 p.m. The President.—Medical Graduates' College and Polyclinic (22 Cheapside, W.C.)—4 p.m. Mr. D. J. Clingie.—(Surgical). 3:15 p.m. Dr. G. E. Herman.—Retraction of the Groin Utirus.

Mount Vernon Hospital for Consumption and Disease of the Chest (111 Tite Street, W.),—2.30 p.m. Dr. H. B. Taylor.—"Heart Diseases in Relation to Phthisia." (Illustrated from Cases.)

West Kent Medical-Chirurgical Society (Royal Kent Dispensary, Greenwhich Road, S.E.),—4.45 p.m. Dr. W. H. Payne.—Case of Ostetricia Deformans. Paper.—Mr. G. O. Smith.—Menstrual Pain and its Treatment.

West London Medical-Chirurgical Society,—8 p.m. Clinical Cases will be shown by Dr. T. B. H. Tilley, Dr. E. A. Saunders, Mr. C. B. Keeley, Mr. McCaum Eccles, and Mr. G. S. Simpkin.

Society of Anesthetists (50 Hanover Square, W.),—Dr. Moritz.—On the Administration of Ethyl Chloride with Nitrous Oxide.

An Actiological Society or London Hospital, W.,—5 p.m. Discussion on the After-treatment of Nasal Operations (excluding Hysterectomy) introduced by Sir T. S. A. Teale.

Medical Graduates' College and Polyclinic (22 Cheapside, W.C.)—4 p.m. Dr. J. B. Horsley.—Clinical (Ear). 3:15 p.m. Dr. J. E. Squire.—Flueal Effusion—Causes and Treatment.

Hospital for Diseases of the Throat (Golden Square, W.),—4.30 p.m. Mr. Parker.—Diseases of the Larynx.

Appointments.

Browne, H. D., M.D., Canfob., F.R.C.S. Eng., Consulting Physician to the Metropolitan Hospital, Kindsland Road, N.E. (12).—Curtice, E. M., M.D., Canfob., F.R.C.S. Eng., Physician to the Metropolitan Hospital, Kindsland Road, N.E. (12).

Jacks, S. F., M.R.C.S. Eng., B.C. R.C.P. Lond., Assistant Physician to the Nottingham Children's Hospital.

Mason, Thomas, M.B., C.M., Ahend, Medical Officer at the St. George's Workhouse, Southwark Union, London, S.E.

Proust, L. Hamitobtob, M.D. Edin., Honorary Surgeon for Diseases of the Ear, Nose, and Throat to the Home in Harley Street belonging to the Governors Benevolent Institution.

Sanborn, Mrs. Anne, M.D., Consulting Physician to the New Hospital for Women, Euston Road.

Thurstone, Hugh, M.D., B.Chap., M.R.C.S. Lond., Assistant Physician to the Metropolitan Hospital, Kindsland Road, N.E.

Vacancies.

Brentford Union.—Dispenser. Salary £100 per annum, with dinner and tea daily. Application to William Stephens, Clerk to the Guardians, Union Offices, Isleworth, W.

City of Liverpool Infectious Diseases Hospitals.—Assistant Resident Medical Officer. Salary £120 per annum, together with board, lodging, and washing at the hospital. Applications to the Chairman of the Port sanitary and Hospital Committee, under cover to the Town Clerk, Municipal Offices, Liverpool.

Gore Hospital.—House Surgeon. Salary £120 per annum, with board and residence. Applications to F. H. Stevens, Hon. Secretary, 146 Milton Road, Gravesend.

Lancashire Inhabitants' Acts Board.—Medical Reformer, Lancashire. Salary £200 per annum, with board, and residence. Applications to Harcourt E. clare, Clerk to the Board, County Office, Preston.

Leeds General Infirmary.—Resident Casualty Officer. Salary £100 per annum, with board, lodging, and washing. Applications to Secretary to the Faculty, General Infirmary, Leeds.

Manchester Royal Eye Hospital.—Junior House Surgeon. Salary £20 per annum, with board and lodging. Applications to the Chairman of the Board of Management.

Royal College of Surgeons of Edinburgh.—Conductor. Salary £100 per annum. Application to James Robison, Clerk to the College, 54 George Square, Edinburgh.

Royal Dental Hospital of London, Leicester Square,—A Dental Superintendent. Salary £250 per annum. Applications to J. Lewis Pink.

Royal London Ophthalmic Hospital (Moorfield's Eye Hospital), City Road, E.C.—Senior House Surgeon. Salary £100 per annum, with board and residence. Applications to Robert J. Bland, Secretary.

Sheffield Royal Hospitals.—House Surgeon. Salary £120 per annum, with board, washing, and apartments. Applications to the Hon. Medical Staff, Dr. Stanley Rixley, 399 Glossop Road, Sheffield.

Sussex County Hospital, Brighton.—House Surgeon. Salary £120 per annum, with board and residence in the hospital, with washing. Applications to the Secretary.

Western Dispensary, Rochester West. (Resident Medical Officer. Salary £150 per annum, with house rooms, coal, light, and washing. Applications to the Secretary.

BIRTH.

Preston.—On Oct. 29th, at 120 Cheetham Hill Road, Manchester, the wife of J. M. S. Preston, M.B., of a son.

Marriages.

Hogg—Ristow.—On Oct. 30th, at St. Ann's Church, Dawson Street, Dublin, Thomas P. Hogg, of Jalgreeting, Blackrock, co. Dublin, to Violet M. eldest daughter of John Armstrong, M.D., of Kenil, Kells, co. Meath.

Deaths.

MURPHY.—On Oct. 30th, at The Oaks, Duffield, Derby, James E. Murphy, L.D.S., R.C.S. Eng., in his 57th year.

POWELL.—On Nov. 2nd, at 32 Hill Place, Kensington, London, widow of the late George Charles Farr, M.D.

BRYSON.—On Oct. 17th, at the Naval Hospital, Devon, after a long illness, the wife of F. Mortimer Cobbold, M.B., and daughter of the late T. Spencer Cobbold, M.D., F.R.S.
Original Communications.

THE IDEAL PHYSICIAN: HIS EARLY TRAINING AND FUTURE PROSPECTS. (a)

By Sir Lambert Ormsby, President of the Royal College of Surgeons, Ireland.

To be an ideal physician should be the aim of every man who embraces medicine as a profession. Everyone is not gifted with the same requirements for a successful career. Some few, indeed, may be born with considerable ability, and at the same time be endowed with a rough, overbearing manner, yet by sheer determination they may force their way into the front ranks of their profession. But such disregard for the feelings of others and such lack of politeness must always tell against their success in the long run. Others adopt this Abernethian style from ignorance. I regard it as fallacious. It appears to be an age when young men are prone to pay but scant courtesy to their seniors, under the mistaken idea that being born in a more enlightened age they could not possibly learn anything worth knowing from those who have gone before. This is a popular fallacy, and the outcome of youthful presumption and want of experience and common sense, for the more a medical student or young practitioner learns the more he appreciates those master minds who have been the pioneers in his profession.

The early training of the ideal physician, as for any other ideal, must be undertaken with very great care. It is, in fact, a preparation for a great and serious struggle—a most momentous battle. A man must start as a student determined to succeed. Fix, then, in your own mind some successful model, and ascertain the means by which he succeeded, whether by tact, industry, skill, or a combination of all these, and then strive with all your might to acquire the same qualities.

Take care in starting that you are equipped with all the necessary armour and weapons for the encounter upon which you have entered. Be industrious, punctual, cheerful, kindly, courteous to your seniors, respectful to your teachers, and prune off those small objectionable asperities which might hereafter be the means of retarding your progress. And, above all, avoid that sorry band of wasters and drifters whose ways and means are so well known to you all. Let your one aim and end be always to achieve the enviable reputation of a good doctor and a courteous gentleman.

As I stand here I see before me a body of stalwart young men, burning with the generous sympathies of youth, strong with robust qualities both mental and physical, standing in the shadow of this old and respected seat of learning, upon the brink of the arena into which they are so soon to enter. Let me now briefly allude to your future prospects. You will ask me what are your future prospects. In answer, I may mention the Navy, the Army, the Indian Medical Service, foreign appointments, ship surgeons, Irish Poor-law Medical Service, and, lastly, private practice.

Of these, I fear I will only have time to make a brief allusion to three. Last year I spoke at length of the favoured conditions of the home Army Medical Service as a career, and I am still in favour of this service, notwithstanding there are yet a few grievances in the R.A.M.C. to be remedied with.

THE NAVAL MEDICAL SERVICE.

This Service is the oldest Service of all, and ought to be one of the most popular. But it is not popular, and you may ask me why. Well, I will try to enumerate a few of the defects of the Royal Naval Medical Service up to six months ago and point out certain of the grievances which in the recent regulations have been remedied.

Grievance No. I.: Late Promotion.—At present the average age of a surgeon entering the Naval Medical Service is 25, he serves until he is 37 before he becomes a staff surgeon, and 45 before he becomes a fleet surgeon, and he may be selected for the higher branches at about the age of 52. No other branch of the Navy has to wait so long to attain corresponding rank; comparison of ages with the executive or combative branch of equal relative rank will clearly show this:—

Surgeons, 25; staff surgeons, 37; fleet surgeons, 45; deputy-inspector-general, 52.

Lieutenant, 21; lieutenant (after eight years’ service), 29; commander, 33; captain, 40.

Under these conditions the naval medical officer may be placed in a position of having to ask leave from a man who is considerably his junior in the Service. To make the Service popular I consider promotions to staff surgeons should be after eight years’ service, and to fleet surgeons after sixteen years’ service. This change, I am informed, on the best authority, will be made in regulations about to be issued in a very few weeks.

Grievance No. II.: Foreign Service.—It is urgently needed that some reform should be made as to the regulation of home and foreign service. At present a staff surgeon returning home after eight years’ foreign service (which may be in the unhealthy climates of the East Indies or West Coast of Africa, for which he gets no extra pay), after six weeks’ leave (that is, only fourteen days for each year spent abroad) is most probably appointed to either the home, cruiser, or Channel squadrons. These fleets have no fixed ports, and are continuously cruising about. Consequently, the staff or fleet surgeon, if married, sees little or nothing of his wife and family, and after from eighteen months to two years of this so-called home service he is again sent abroad for another term of foreign service. To remedy this there should be a fixed regulation that every medical officer returning from a foreign station should be entitled to a period of shore or harbour service.

Grievance No. III.: Compulsory Half-Pay.—This has by no means been done away with. The great objection is not so much the loss of annual income, which is bad enough, but also the loss of time. The time spent on half-pay has to be made up before retirement.

Grievance No. IV.—Another grave injustice is that a number of medical officers wait patiently until they have completed twenty years’ full-pay service (the time
spent on half-pay having to be made up), this being the earliest period when they can retire with a pension. But this long-looked-for reward to-day has arrived, for it sometimes happens that the unfortunate medical officer is serving abroad. He is informed on applying for retirement that his services cannot be spared, even if he offers to pay his own passage home and his successor's passage on the board of the ship on which he serves under them. An inspector-general, who is supposed to rank with a rear-admiral, before he can get a man punished has to report him to the executive authorities of the department, and much time is wasted before the charge is heard or the offender punished. Surely the sick pay staff ought to be under the control of the naval medical officer just as the men of the R.A.M.C. are under the control of their officers in the same corps.

Grievance No. VI.: Medical Guard.—It is the recognised custom in the present day, where two or more ships are in harbour together, for the naval medical officer to take it in turn daily to keep medical guard. This means that a medical officer of the ship having the medical guard has to remain on board his ship to be ready to go to any emergency case in any of the other ships should they arise, and always available if the ships are ordered to sea, or to any duty off the ships in harbour. Although this is practically the custom and works admirably, it is not as yet embodied in the King's Regulations, and the result is that some captains still insist on always having one of the two medical officers belonging to their ship on board, although the medical officer of the guard is close alongside and capable of being on board in five minutes on signal being made for him. To have his ship kept on board even an alternate day for the whim of an individual captain is very galling, more especially as it is only done in one or two ships in a fleet. To obviate this grievance it should be clearly laid down in the Regulations that medical guard is to be recognised in all ships.

There are many other petty disadvantages which irritate the naval medical officer, that a little rearrangement could easily remedy without any loss of discipline or efficiency. For instance, there is no encouragement of individual responsibility at medical surveys. An inspector-general, ranking as rear-admiral, is forced to sit under the presidency of a post captain or even a commander, who is years junior in service. In this course, I do not wish to deny that the captain should command his own ship, but I do think that if the status and position of the naval medical officer is to be upheld he should have entire control of the sick and the sick book and should also be able to punish them for non-observance of discipline in their special work, should necessity arise—the same as in the R.A.M.C. A new set of regulations has just been issued, and some of the matters I have complained of have been remedied; but many grievances still exist which, I fear, if not removed, will act as a barrier to the entrance of efficient men into the Service. The present Director-General, Sir Henry Norbury, has done more to remove defects than any of his predecessors, and, I know, has the interests of the Service at heart, and is only too anxious to see his branch brought into efficiency and popularity; but I have no doubt that when he suggests improvements he is stopped by the Treasury, which will not sanction any improvement that costs additional money. The Government yearly spends millions on the building of war ships intended to inflict death and suffering on our fellow creatures, and how much more in humane cases should they be willing to expend, then, on a branch of the Service whose mission it is to prevent or cure disease and alleviate the suffering inflicted by shot and shell? If the distinguished Director-General, Sir Henry Norbury, fails to induce the Admiralty and the Treasury to amend these grievances by mild expostulation, they will be forced in the long run to yield, because men will not go where discontent and limitation of status are maintained. In the end the Admiralty will have to follow the example of the Army, and at once accede to the suggestions of an energetic and independent Medical Advisory Board constituted on the same lines as the R.A.M.C., but called in the Navy the Medical Consultative Board.

The R.A.M.C. now gets plenty of well-qualified cadets, but in the Naval Medical Service there is a deficiency of over fifty surgeons. It is to be hoped before long to see these grievances removed and good and efficient men more induced to enter it in large numbers.

I would now like to say a few words about another Service which has somewhat grown into disfavour, The Indian Medical Service.

I have just read an official memorandum dated India Office, October, 1903, in which certain alterations are effected for the improvement of the Service. First, I find by the new regulations that the pay of the Indian military medical officer is increased, although the increase sanctioned is not very large. A lieutenant's commission will in future date from the date on which his course of instruction commences, and he may be promoted to captain in the fourth year of his full years' service, the same as the R.A.M.C., but he will be required after eighteen months' service to pass an examination in military law and military organisation.

The unemployed pay of a lieutenant in India will be in future Rs.4,450 in place of Rs.4,200; when placed in permanent medical charge of a regiment his pay will be Rs.900; in place of Rs.4,450. On promotion to captain, if in substantive charge, he will receive Rs.550 in place of Rs.4,600. After seven years' service there is an increase from Rs.600 to Rs.670; and after ten years' service, from Rs.670 to Rs.700. The pay of a major after fifteen years' service, who is in substantive charge, is increased from Rs.800 to Rs.900; and of a lieutenant-colonel in substantive charge Rs.1,750. A lieutenant-colonel who has twenty-five years' service will in future receive Rs.1,300 if in substantive charge, and if specially selected for increased pay, Rs.1,400. The pay of a surgeon-general is raised from Rs.2,700 to Rs.3,000. In justice to the officers now serving it is hoped that the regulations will be retrospective as far as they are concerned, and that the regulations will have a retrospective effect from the date on which increased pay under the recent act was granted to officers of the R.A.M.C. serving in India, to which change I alluded in my address last year.

Following the precedent set in the case of the R.A.M.C., it is now provided that specialist pay at the rate of Rs.60 a month will be granted to all below the rank of lieutenant-colonel who may be appointed to certain posts, and another clause provides that extra furlough may be granted to officers desirous of pursuing special courses of study, at the rate of one month's furlough for each year's service, up to twelve months in all. There are other important improvements set out in this memorandum, but there are grievances and drawbacks still remaining. When these are removed I believe the Service will be popular again, and many efficient young qualified men will be eager to enter it. The next and last Service I will allude to is nearer home. It is The Poor-law Medical Service.

Last year I thought I said all that the head of a college could possibly say to you on the subject. But twelve months has proved to me that if the Poor-law medical officers are to be supported in their manly fight against injustice and dishonesty, it behoves all those in any position in the medical profession in whose cause of humanity and justice they should be willing to expend, then, on a branch of the Service whose mission it is to prevent or cure disease and alleviate the suffering inflicted by poverty and misfortune, that the distinguished Director-General, Sir Henry Norbury, fails to induce the Admiralty and the Treasury to amend these grievances by mild expostulation, they will be forced in the long run to yield, because men will not go where discontent and limitation of status...
asked what has been done for the Irish dispensary doctor, I regret to be obliged to say—nothing.

Now let me enumerate the grievances and disabilities which an Irish dispensary doctor labours under at the present time, as related to me by one who was an Irish dispensary doctor for over twenty-five years. His first and most pressing grievance is that in many instances the salary is not sufficient to pay the expenses of covering the district. Then he declared he was asked for superannuation, but leaves him entirely in the hands of men who are a changing body, liable to be swayed by the transient influences of the moment, and who, perhaps, resent a dispensary man as being, in the words of a popular Irish M.P., a "blue-blooded official."

When such is the feeling of a Member of Parliament towards our dispensary medical officers one can easily guess in what estimation they are held by the rank and file. The dispensary officer becomes sick and tired of the everlasting abuse showered upon his colleagues at the different weekly meetings of the Boards of Guardians throughout the country, and the treatment of the Local Government Board is no better. They heap new duties on the medical officers, and when for once a generous and reasonable Board of Guardians grants an increase of salary, they will not sanction it. Then the mode of election, many legal actions and cases of malversation in connection with the degradation involved in having to solicit the votes of the class of men who now administer the public affairs of the country, where the most inexperienced of the class are legally qualified), and who have left the political influence would beat the President of the Royal College of Surgeons for a dispensary or union if he were a candidate for one.

The present grievances of the Service are therefore narrowed down under six heads:—(1) Insufficient salaries, which should be raised to at least £200 a year. (2) A medical officer ought not to be compelled to pay the travelling expenses incurred in the discharge of his public duties, unless otherwise specially agreed upon; and, if so, by order of a superior, or by consent of the body to which he is attached. (3) To amend Dispensary Rule 28 so as to give to medical officers the leave the Local Government Board intended as a matter of right they should have, viz., a full month's holiday in the year. (4) To repeal Clause 6 of the Local Government Amendment Act, so as to permit the recoupment from Imperial sources of the full half of the salaries paid to medical officers and not otherwise paid, but to be paid to the salary previously paid. (5) Superannuation—that superannuation to medical officers be paid on the Civil Service scale, and that it be mandatory and not optional. (6) To alter the present mode of election and have it placed in the hands of the Service. The practice of making the number of candidates for each constituency greater than the number of vacancies, which means the Superiority of the man with the largest pocket. Thus the medical profession has of necessity to look to the sideways and to the money, and the patient, unable to afford an educated medical man, is left to the mercy of any one who may be appointed.

The amelioration of these conditions rests with yourselves. Many of you will be shortly qualified, vacancies occur nearly every week, but I urge you in the strongest manner to refuse to enter a Service which imposes such degradation on its officials. Never before in the history of Ireland has the profession risen as one man to revolutionise old traditions by joining the Irish Medical Association, and so enrolling recruits who were afraid to utter one word of complaint lest dismissal should follow. You ought to prefer to break stones on the roadside sooner than enter a Service which treats the nation with contempt, and the recreants who are mean enough in face of such a warning to compete for dispensars at a lower salary than £200 a year deserve to be regarded as unworthy of the name of men. If they are subsequently treated badly it is only the proper punishment of persons so far forgetful of the duty they owe to their profession and the respect they owe to themselves. I am well aware of the possibility incurred as President of this College in speaking in such condematory terms of a Service, even though I believe it to be the worst in Europe. But I urge you to stick together. Become members of the Irish Medical Association; be determined, and the Government must give us something to make us happy. The Service must be properly relieved and the Service made efficient. I would also impress on those of you who will soon be qualified the necessity of joining as members of the Royal Irish Medical Benevolent Fund, an object to which every practitioner should at once begin to subscribe. It is, in fact, a form of personal insurance, which, like the widow's cruse of oil, will never fail to be of use and advantage. None can tell when adversity will overtake him, in the form of loss of money or post, through ill-health or death, and it is comforting to know that, if you are a subscriber to the Medical Benevolent Fund, before such calamity overtakes you, the committee will be at your side to give your wife and children preference. Let the first money, therefore, that you earn after qualification be handed to the Royal Medical Benevolent Fund, and lay up there a treasure which in need and danger will be at the disposal of those who are near and dear to you. Another piece of advice I will give you. The moment you are a member of the profession join a Medical Defence Association.

It only costs ten shillings a year, and may be of vast importance to you later on in the practice of your profession. The value of insuring against attacks which are often made against medical men by unscrupulous persons for the purpose of levying blackmail is well known. And there is no doubt that if all members of the profession would join the Medical Defence Association, many cases, and many cases of professional ruin and financial loss would be done away with. A doctor in this city who had a personal charge levelled against him by a former patient was mulcted of a large amount in defending his character and profession. He had about a year previously been a member of the Medical Defence Union the case would have been taken up by its solicitors and defended by its funds. Members of the profession are liable to be assailed by the attacks of evil-disposed persons, and it behoves all those who value their reputations to prepare and insure against such a contingency. We must also continue to fight ignorance and misconception until the general masses are convinced that medical men and the profession and social position the profession and its members ought to occupy. One deprecating influence is the absence of suitable State recognition for the leaders of medicine and surgery. In the constitution of our governmental system there should be (and it is imperatively called for) the appointment of a Minister of Health or Sanitary Science, who should occupy a seat in the Cabinet, and his duty solely to be assailed by the attacks of evil-disposed persons, and it behoves all those who value their reputations to prepare and insure against such a contingency. We must also continue to fight ignorance and misconception until the general masses are convinced that medical men and the profession and social position the profession and its members ought to occupy. One deprecating influence is the absence of suitable State recognition for the leaders of medicine and surgery. In the constitution of our governmental system there should be (and it is imperatively called for) the appointment of a Minister of Health or Sanitary Science, who should occupy a seat in the Cabinet, and his duty solely to be ably filled by a person of the highest character, and not, as up to the present time, by a mouthpiece of the party. My suggestion may be Utopian, but if England intends to take a creditable place in the future among the great nations of the earth at that each class of the community is taken in and ordered, for government in the present day and government a hundred years ago are very different matters. Scientific medicine must, and will, take an exalted position in the world when the component parts of the great ship of State are properly constituted. The profession of law, with its legal peers and lord chancellors, the Army and its military lords, and the Church with its spiritual peers, must, in justice, make room for their Cinderella sister, medicine. Therefore the Minister of Health and Sanitary Science must be an appointment in the near future. I presume there is no one among us who will doubt my class prejudice comes in, and doctors are excluded from taking their seats on the Privy Council. Would anyone with a grain of sense give the reason of this? Why should the leaders of our profession not be entitled to be called the Right Honourable? Men far inferior, other men far inferior, it may be, in birth, position and scientific attainments? On what grounds are we excluded as a class? Simply, I would say, because
we as a body have been over modest and have never attempted to break down that ignorant prejudice and prove our own importance, an insistence that science will, and must, have a place in every arena in the Kingdom.

I have mentioned the word "ideal" in describing a physician, let me tell you in a few words what I mean by the term. The profession of a doctor is a noble one, and should ennoble those who practise it, deepening the sympathy and idealising the life. No man knows better the frailties of his fellow-creature than the doctor—no man has more reason, perhaps, to think pitifully or severely, or even contemptuously of mankind. But there is no man more broad in his charity, more lenient in his judgments, than the ideal doctor. He sees everything, yea, he sees everything in its fulness. In many families the doctor is held in as great love and reverence as the priest. He is with them in trouble and in joy, and from his lips issue the facts of life and death. He must bend his ear to catch the first wailing cry when the infant takes up the burden of life, the last tired sigh when the old man lays it down. He has to wrestle with the great foe of humanity at every turn; to him the blanched mother may owe her fluttering life when giving birth to another; it is he who, when friends are paralysed with fear of contagion, must face the hideous features of cholera, typhus, small-pox; he must show a calm front to the demands made upon his vital energies and the exaggerated expectations formed of his power to aid, while science stands humbled and impotent in the presence of death. With all his deep learning the ideal doctor is modest, with all his knowledge of the world he is tolerant, he is wise as well as witty, gentle as well as powerful, a tower of strength to the weak, and ever on the alert to shield the reputation of a brother practitioner. It is a life of splendid opportunities for good, if lived as the ideal physician may live it, and it is open to you all to aspire, at least, to that ideal.

Many of you are now, as I have said, on the threshold of active life. There is always something that predisposes to reflection in the communion of mind between one who is on the verge of manhood and one who has already passed its meridian. It is natural at my age, when looking back at a long life of professional toil and anxiety, that many things should wear a more serious aspect. I might almost say a sadder one, than at yours. Yet I confess that when I see around me so many robust frames and ardent spirits, trained with so much success and the service of the state and country, I am disposed to view your future prospects as hopefully as you do yourselves. May all success attend you in your future endeavours. May the name of Irishmen, in your safe keeping, continue to be held in high honour amidst the nations of the world. And if in the days of your matured success your thoughts should wander back to this day and to the memory of him who, through the favour of the Fellows of this College, is in the position of addressing you, think of him as of one who while he lived never ceased to entertain a warm sense of your kindness and a lively interest in your welfare as true gentlemen, and, as nearly as you can attain, ideal physicians.

THE TREATMENT OF CONSUMPTION BY TREATED AIR.

By GEORGE STOKER, M.R.C.P.I.,
Hon. Medical Officer, Oxygen Home, Fitzroy Square.

One of the most recent treatments for consumption to which medical science has resorted is what is popularly known as the "open-air treatment." The special principle of the treatment is not so much to rely on the use of drugs, &c., as to place the patient in those surroundings of atmosphere which enable him most successfully to combat the disease. These conditions are found to the highest degree in such places as Davos, Colorado, or the Peak of Tenerife. The air in these localities is distinguished by its purity, dryness, the presence of ozone in considerable quantity, and its comparative rarefaction.

The other characteristics of the "open-air treatment," such as diet, sanitary surroundings, exercise—active or passive—cheerful society, &c., can be and are obtained elsewhere, but the peculiar and essential characteristics of the sanatoria above mentioned must be sought in their atmospheric surroundings. But under the most favourable circumstances, the open-air life and constant exposure necessary to ensure the full advantages of the treatment may themselves be a source of danger to the patient. This is especially the case in the English climate; it is obviously impossible to pursue a manner of life in England which is possible and beneficial in more favoured climates. The object, therefore, must be to adopt a form of treatment which will avoid the disadvantages inseparable from the English weather, and at the same time to secure the atmospheric surroundings which are the chief curative agency in those sanatoria where the open-air system is successfully carried out.

In considering how this end might be best accomplished, it became apparent that the most practical means would be to enclose the patient in a limited air-tight space, into which air possessing all the necessary characteristics could be passed.

With this view, cubicles were constructed in which patients could conveniently spend the greater part of their time, and into which a constantly renewed supply of prepared air could be drawn. These cubicles have been in use for over two years, and have answered all expectations. They are now working, and are at all times open to the inspection of those who desire to examine them.

A cubicle is constructed of wood and glass, the lower part of the walls being made of wood, and the upper part of polished plate glass. At one end is a single door which closes with a joint that renders it air-tight, and at the opposite end, attached to the wooden part of the wall outside, and opening into the cubicle, is the small chamber in which the air is treated. This chamber is connected with the outer air by a ventilating shaft 12 in. by 6 in. On top of the cubicle at the door end is a square chamber which contains
the "exhaust fan." An exit ventilating shaft leads from this chamber through the roof of the building in which the cubicle is placed.

The air, as will be understood, is drawn into the cubicle, passing through the preparing chamber, is first filtered through layers of cotton-wool, in order to remove all mechanical and organic impurities. It is then dried by passing through perforated trays charged with chloride of calcium, and lastly it is ozonised before entering the cubicle. The ozonising is effected by an ozoniser placed in the chamber, and which is called into action for five minutes for each quarter of an hour by means of an automatic clock, which makes the necessary electrical connection at the times stated.

Owing to the fact that the output is a little more than the inlet, the atmospheric pressure inside the cubicle is somewhat reduced and the air comparatively rarefied. The patients spend about eighteen out of the twenty-four hours in the cubicle, and so far from feeling any inconvenience from their somewhat limited surroundings, are unwilling to return to the ward, as they find a difficulty in breathing when there as compared with the time spent in the cubicle.

Such, in a few words, are the principal characteristics of the cubicle as it now stands.

It was anticipated that the time now spent by the patient in the cubicle should be much, if at all, extended. Two and a half hours are necessary for meals, and three and a half hours should be devoted to exercises. It might, at first seem somewhat like solitary confinement for a long period, but it must not be forgotten that the whole and sole reason for a patient's treatment is to try and get well, and within reasonable limits everything must be subordinated to that end. In the summer months, and in exceptionally dry and clear weather, the time spent in the cubicle would naturally be less than above indicated, being alternately spent in the open air.

The principle of the present scheme is to ensure a full control of the air inspired by the patients. It is for this reason the cubicle system has been adopted. The larger the space the more difficult it becomes to control the air supply, and especially to regulate the artificial introduction of oxygen or oxygen. Both these gases are very volatile and extremely diffusible, and oxygen certainly cannot be stored, but must be used as soon as it is generated. Even in a small room these difficulties do exist, and therefore, within reasonable limits, the cubicle provides the most essential solution of the difficulty.

The beneficial influence of the rest in the treatment of pulmonary disease must not be overlooked. While, on the one hand, a certain amount of muscular exercise, active or passive, walking or massage, is not only desirable, but necessary; on the other hand, rest for long periods in the recumbent or semi-recumbent position is equally to be desired, as these latter circumstances relieve the strain on the circulatory and respiratory organs, both of these systems being more or less impaired by the presence of tuberculous bacilli.

To this end the system of treatment under consideration offers every facility, as practically for eighteen out of every twenty-four hours the patient is resting.

Speaking generally, the cubicle system offers a new field of treatment. Many patients suffering from incipient consumption are at work during the day in what may be considered as fairly sanitary surroundings, but at night sleep under conditions that can only result in the rapid advance of the disease on the patients themselves and to the infection of those about them. So large is the number of infected persons that to send them all into pure country air seems almost a Utopian idea. Many must go on working on account of those dependent on them, and for other reasons. Is it not possible that the cubic system might be extended to many districts in towns by the foundation of institutions of very simple construction, where such workers as must live near their places of employment could at least spend their sleeping hours under the most favourable conditions, or private persons suffering from chest complaints could have cubicles constructed in their own homes, and thus obtain the advantages of the "open-air" treatment without its drawbacks?

The following are notes of cases that have been treated.

J. M.—This case may be described as one of chronic phthisis. The patient, aged 35, had suffered for some years from chronic bronchitis and emphysema. Three years before coming under our treatment pulmonary tuberculosis had set in. The lungs were more or less infiltrated throughout, and there were colonies in the apices of both lungs, profuse muco-purulent expectoration amounting to ten ounces in twenty-four hours, with slight hemoptysis. There was intense anemia, and it was with difficulty he could walk up a short flight of stairs. Tubercle bacilli were present in large quantities in his sputum. There was slight hectic fever, which soon disappeared. The patient weighed on entry 7 st. 2 lb. The patient was four months under treatment. The expectoration had been reduced to about a quarter of an ounce in twenty-four hours, and the purulent character had quite disappeared. The breathing had greatly improved, and examination showed that the cavities had gained 10 lb. Tubercle bacilli had quite disappeared, and the weight had increased to 8 st. 12 lb. Considering the nature of the case, these results cannot but be regarded as remarkable, and later accounts of the patient show that this improvement has been maintained.

2. Female, aged 33.—Two brothers and one sister had died of consumption. The patient suffered with cough, muco-purulent expectoration, and had hemoptysis. Tubercle bacilli were present in small quantities. She was under treatment for one month. The purulent character of her sputum and the tubercle bacilli quite disappeared, the hemoptysis ceased, and the patient gained 4 lb. in weight.

3. Female, aged 24.—Had hemoptysis, night-sweats, loss of weight, cough and muco-purulent expectoration. The patient was seven weeks under treatment and gained 7 lb. during that time, and all the symptoms above mentioned disappeared. The apex of the left lung was affected, there being prolonged expiration with jerky respiration and dulness on percussion. All these signs cleared up and the doctor who sent the patient to us confirmed our examination and expressed himself surprised at the remarkable change that had taken place.

4. Girl, aged 15.—This was a case of so-called "incipient" consumption. Patient suffered from purulent expectoration with hemoptysis and tubercle bacilli could be discovered. With one month's treatment, symptoms above mentioned disappeared and patient gained 6 lb. in weight.

5. Male, aged 22.—Severe near relations died of consumption. He had large cavities in the apices of both lungs, repeated hemoptysis, profuse muco-purulent expectoration, night-sweats, severe cough. His average evening temperature was 102°, and the patient had his cubicle for six months. He was six months under treatment; at the end of that time his temperature was normal, the hemoptysis had ceased, the expectoration was healthy, the tubercle bacilli had disappeared, and he gained 10 lb. in weight. The cavities had cicatrised and contracted, so much so that the top of the left chest was fixed.

The most remarkable results of this system of treatment are to be seen in the reduction of the temperature and the disappearance of the tubercle bacilli. It may be stated that the patients had the usual meals, breakfast, lunch, tea and dinner or supper, in fact, had an ordinary diet, and the so-called "stuffy" system was not practised.

A QUANTITY of pure radium has been generously placed at the disposal of the medical staff of the Cancer Hospital, Fulham Road, S.W., and the staff are making arrangements for an extensive trial of this new method of treatment to be undertaken. Within the number of inoperable cases at their disposal the staff will be able to give this new treatment a fair trial.
PROTARGOL
IN THE TREATMENT OF GONORRHEAL OPHTHALMIA.

By Arthur Greene, B.A., M.D., &c.

Gonorrhoeal ophthalmia is undoubtedly one of the most pernicious diseases which the ophthalmic surgeon has to combat. The most careful and constant attention on the part of the surgeon and nurse only too frequently ends in disaster; this makes me think that if it be possible to report the successful results obtained in three consecutive cases treated, during their acute stages, with protargol. I may say that the gonococcus having been found let no doubt as to the true nature of these cases.

The first case was a little boy, aged 3, with the mother's history that his little sister, of about the same age, had a "discharge" from her vagina, and that the children used to bathe at the same time in one bath and use the same towel, &c. The eyes had been bad some three days at least before admission; there was a very profuse discharge from both eyes with a considerable amount of ocular conjunctival oedema, swelling of the lids, and the other usual signs of the disease; the right cornea showed at its lower part a small ulcer. The child was put under treatment as follows:—Washing out every two hours with the following lotion: Acid. boric., gr. 15; zinc sulph., gr. 1; acetic acid, 2 dr.; on alternate occasion — i.e. every fourth hour; after being washed out with the boric lotion, a 10 per cent. solution of protargol was kept in contact with the conjunctiva for three or four minutes. This can be best effected as follows:—A small (holding about ½ oz.) rubber nozzled bulb is used to drop the protargol solution into the eye, held open, and in this way the eye can easily be kept in a puddle of protargol for several minutes; finally, some vaseline was smeared along the lid margins to keep them from sticking. After forty-eight hours' treatment the discharge was markedly less, and washings out were done three-hourly with use of protargol six-hourly, or more frequently if on any occasion there seemed to be more discharge than usual; after a further period of twenty-four hours, four-hourly washings were used, and protargol some three times in the twenty-four hours, as purulent discharge had almost entirely stopped. On the seventh day, counting the day of admission, the child was discharged from hospital, with eyes free from discharge, an injected ocular conjunctiva, and the ulcer on the cornea not more than an admission. This ulcer was somewhat troublesome to get to heal, which it did in about fourteen days under treatment with pad and bandage, atropine, and warm boric baths.

The case of a lad, aged 21, who contracted his eye trouble from a gleet, the result of gonorrhoea contracted some five weeks previously; he gave a history that three days ago, when at work in his office, his left eye became very painful, so much so that he had to give up work in a few hours, and that there was much discharge. On admission there was free muco-purulent discharge with oedema of conjunctiva with no involvement of cornea. He was treated with washings out with zinc chloride, gr. 1 to oz., and application of protargol solution twice a day for four days; there was then a good deal of discharge, but not at all purulent, and much injection of the conjunctiva. Protargol was then stopped. The eye was slow to quiet down, and even on his leaving hospital, eleven days after admission, there was still much conjunctival injection, although all discharge had ceased. I am inclined to think that a more frequent use of protargol in the commencement might have effected a more rapid cure in this case. The cornea was not at any time involved. The eye was quite normal when seen ten days after leaving hospital.

The third case was of great interest. Patient, a clerk, aged 35, contracted gonorrhoea about a week before admission. He presented himself late on Christmas Eve night last, stating that his eye had been bad two days. In this case the oedema of conjunctiva and swelling of lids was very great, the eye only being opened a little with difficulty. At this stage the cornea was unaffected. He was put on two-hourly baths with the same boric acid and zinc sulphate lotion as Case 1, followed on each occasion by the application in a similar manner of 6 per cent. protargol, and he made excellent progress. On the evening of the day following admission, an ulcer commenced to form on the lower part of the cornea close to the limbus. Two days later the ulcer had got larger, discharge still plentiful; hourly baths during the day (two hourly at night, as before), with the application of protargol (now 12 per cent.) two-hourly, as usual. Gutt. eserine (gr. 2 to oz.) twice daily. The next day, December 28th, the ulcer was still larger, now occupying practically all the lower half of the cornea; perforation seemed imminent, there was still plentiful discharge and much swelling of the conjunctiva; indeed, as regards saving the eye, the case looked hopeless. However, I determined to persevere to the utmost, and that evening, at the expense of his sleep, put him on hourly baths night and day, still using the protargol two-hourly. The following evening the ulcer apparently had not increased in area, and discharge was certainly somewhat less. The one-hourly baths were kept up until the evening of December 31st, when the ulcer appeared more healthy, and the discharge was markedly less, baths were then changed to three-hourly, and in a day or two treatment was reduced to six-hourly baths and protargol about once in twenty-four hours for some three days. All discharge had stopped by January 2nd, by which time the conjunctival swelling had gone, but there was much injection. The ulcer healed very slowly under usual treatment, and it was not until January 27th that it no longer stained with fluorescein at its centre. It left a very dense opacity, which when the patient was again seen, the end of the first week of February, appeared a little clearer, and the patient himself says the sight is getting clearer. A Buller's shield was, of course, used in both above cases. The bowells kept very free, and the latest case was given quinine sulph., gr. 1, every two hours.

The chief points to attend to in the use of protargol in these cases are, first, strength of solution; secondly, method of application: thirdly, when to stop it. A 10 per cent. solution appears to be the most suitable, a less potent solution acts more slowly and with much less certainty. The method of application described under Case 1, allows one to proceed with great confidence, in continuous contact with the solution for a considerable time. Stop protargol when purulent discharge ceases. The great danger of too much protargol is the fact that it tends to clot the ocular materials forming a sort of membrane, thus seriously endangering the blood supply and nourishment of the cornea.

ENTERECTOMY
FOR TUBERCULOUS STRICATURE OF THE INTESTINE. (a)

By Francis M. Caird, M.B., F.R.C.S.,
Assistant Surgeon to the Edinburgh Royal Infirmary, Lecturer on Surgery in the Edinburgh School of Medicine.

The author remarked on the comparative paucity of English medical literature on the subject, papers for the most part dealing with isolated cases only. This communication was based on an experience of eleven cases. Tuberculous stricture was generally a fibrous hyperplastic change, and might be divided into three varieties:—(1) that due to a papillary outgrowth in the lumen of the gut, (2) one in which an annular fibrous diaphragm occluded the bowel, and (3) a bobbin-like obstruction, where the wall of the intestine was thickened

(a) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, November 4th, 1903.
over an inch or more of its length. As to the age of the patients, in most cases the condition was found before the thirtieth year, though in several of the cases the sufferers were of considerable age, and the history of cases of tuberculous sacral abscess was also rather common. The appendix and malignant disease were the most important of the other possibilities which had to be considered. The localisations of the tumours were usually at the base of the colon, not infrequently extending over a number of years, with constipation, colicky pain, abdominal tenderness, borborygmi audible both to the patient and his neighbours, and vomiting as its most prominent symptoms. Hematemesis, diarrhoea, melena, and haemorrhoids were less frequently met with. On examining the abdomen per rectum it was generally advisable to look for the presence of gas, as it was found that the gas was often present in the rectum, and that the rectal examination was of great value in this condition.

The principles of enterectomy for tuberculous stricture were very much those governing the proceeding when undertaken for other conditions, but in the cases where considerate operation was usually required it was generally advisable to exhaust the bowel by circulating fluid, and to cut the intestine at a point where the disease was least advanced, so that the sutures might pass through the walls of healthy intestine. Clinically, cases as they presented themselves to the operator fell into three groups—(1) Where the lesion was local, the stricture should be removed freely for fear of infection of neighbouring parts; (2) In cases where the disease was of long standing, the disease might be present in other parts of the intestine, and in cases of generalised disease, it was better to cut the intestine at a point where the disease was least advanced, so that the sutures might pass through the walls of healthy intestine. (3) When the gut was surrounded by quantities of inflammatory material, and the mass attached as well as the adjacent viscera, it might be found advisable after dividing the bowel above and below, and uniting the healthy ends, to bring the two cut edges of the gut opening into the peritoneal area to the skin surface and allow them to discharge there. In either case an intestinal anastomosis, short-circuiting the bowel, might be better. Of his eleven cases four had died, seven recovered, three being alive from five to ten years after operation. Three of the oldest patients had died; thus appeared that the prognosis was better in young patients. Dealing with some of the post-mortem results in his cases he instanced the case of an elderly man in whom enterectomy had been performed, and who died of syncope a year later. In this case it was of interest that there was absolutely no contrac tion of the intestines. The site of union was certainly a second case, from which about five feet of small intestine were removed, the appearance of the growth very closely resembled malignant disease. A gummatus nodule was found in the liver, and while histologically tubercle was undoubtedly present there remained some doubt as to whether it was not complicated by sarcoma. Death took place from carcinoma with symptoms of ascites and epigastric months after enterectomy. In the third fatal case double enterectomy had been done; death ensued within the year from glandular infection. In one of the cases after excision of the ileum and greater part of the ascending colon, a fistula ultimately developed and, notwithstanding attempts to close the fistula by the patient himself, he was going downhill. Commenting on the post-mortem results attention was drawn to the comparative frequency with which tuberculous lesions of the abdomen were complicated by malignant disease, and the difficulty which sometimes existed in differentiating between them, even histologically. Thus in his series he had one probably associated with sarcoma, another with colloid cancer. The ileo-caecal region was by far the commonest site, the affection being rarer as one passed up. Bearing in mind the resemblance it might present to malignant disease it was suggested as a point worthy of consideration whether some cases of enteritis of the pylorus might not be really tuberculous. In all of his post-mortem tubercles of the lungs had been present.

The Out-Patient Department.

CARDIFF INFIRARY.

By W. MITCHELL STEEVES, M.D., M.R.C.P.Lond., Assistant Physician and Pathologist to the Cardiff Infirmary.

In the out-patient department of a hospital, and in private practice, the chief function of the physician who is seeing a large number of cases is to pick out the wheat from the chaff. There is no class of cases which is liable to give rise to more difficulty and mistakes in diagnosis than those which come under the above head.

The diagnosis of the presence of intra-thoracic pressure is founded upon symptoms and physical signs, both of which are often more or less obscure. The special symptoms are the so-called "pressure-symptoms" due to pressure by the new formation upon nerves, air tubes, esophagus or blood-vessels, and in some cases these symptoms are very striking, while in others they are much less evident. The patient may complain of pain in the chest, shoulder, neck, or arms which is often spoken of as "rheumatic" or "neuralgia," and consequently its real significance is apt to be overlooked, though its presence and its usual obstinate character should never fail to draw attention to the possible presence of "pressure," and, therefore, lead to a careful examination. Dyspnoea is a symptom frequently complained of, and in some cases is marked paroxysmal in character, and of which the degree is out of proportion to other symptoms or to physical signs in the chest will often point to pressure on the air tubes. In some cases the dyspnoea is markedly inspiratory and accompanied by "stridor," or more or less reported with blood. In some cases hemoptysis is a marked symptom, while in others, from pulmonary complications, there may be spitting of pus or even of gangrenous matter.

These are briefly the symptoms on account of which the patient is liable to come under observation, and the most characteristic are the laryngeal ones, which...
BRITISH SANATORIA FOR CONSUMPTION.—XIX.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE OCKLEY SANATORIUM, SURREY.

In the mild, sheltered, and peculiarly charming village of Ockley, situated in one of the most picturesque districts of Surrey, Dr. Clara Hind has recently established a small sanatorium for the treatment of easy cases of pulmonary tuberculosis.

A large, well-placed, excellently constructed modern house has been modified to meet the requirements of a hygienic home. The rooms are of convenient form and size, well lit, with ample window space, and provision has been made whereby comfort may be enjoyed and yet a practically open-air existence always secured.

The house stands at a short distance from the road, and is surrounded by lawns and gardens; and in close proximity are fields which offer ample opportunity for the conduct of carefully regulated exercise.

From the house charming views of Leith Hill and the well-wooded surrounding country may be obtained.

The climate is particularly mild, much sunlight is usually enjoyed, shelter is secured from the north, and by a little arrangement protection can also be provided from the prevalent south-west winds. The air is pure and bracing, and the climatic conditions generally are such as allow of practically a constant existence in the open. A large day shelter, open to the south, is very popular, and forms an admirable sun trap. There is also a good revolving shelter. The grounds are suitable for the erection of many similar structures.

On the occasion of our visit towards the end of October, we found all the patients out of doors, and were informed that it had been the custom for them to spend all meals, except breakfast and dinner, in the open. We carefully inspected the accommodation provided for the patients, and are of opinion that the Ockley Sanatorium is well fitted for the treatment of early cases of phthisis. Advanced cases, we were told, are not admitted.

Dr. Clara Hind, the proprietor and resident physician, has had much experience in the conduct of a sanatorium, having been resident medical officer for two years at the Ockley Sanatorium, and has been trained at Rudgwick. Treatment, as far as we could gather, is carried out on sound rational lines, and in accordance with, and strict adherence to, modern hygienic principles.

Dr. Hind shares the life of the patients, and personally supervises the details of treatment of each individual, and since the number of cases admitted is necessarily small, the comfort and convenience of every patient is carefully studied.

The water supply is derived from a well in the grounds; and the sanitary arrangements are apparently good. Lighting is provided by oil-lamps. Each room has an open fireplace, but artificial heating is not resorted to in the sanatorium to any extent.

Southfield, as the sanatorium is called, is a good example of a hygienically conducted home particularly suited to the needs of middle-class patients of both sexes.

Dr. Hind informed us that she is contemplating a considerable extension, whereby it is hoped provision may be made for patients unable to pay more than 30s. a week.

The present fees are two and a half guineas weekly inclusive, except personal laundry.

Ockley is situated twenty-nine miles from London on the main line of the L. B. & S. C. R. The sanatorium is a mile from the station.

SIR GEORGE T. GOLDBIE presided at the opening dinner and meeting of the thirty-sixth session of the Royal Colonial Institute at the Whitehall Rooms Thursday (Tuesday), when Major Ronald Ross gave an illustrated lecture on 'Malaria in the Colonies and India.'
"Congenital Hemihypertrophy of the Tongue." There was considerable papillary outgrowth, and excision was advised in view of the possibility of subsequent epithelioma. (2) A case of dislocation of the acromial end of the clavicle treated by closed method.

Dr. Allan Jamieson showed (1) a case of "Parakeratosis Variegate"; (2) a case of "Myositis Fungoides in the Erythodermic Stage"; and (3) a very severe case of "Ichthyosis," in which surprising benefit followed the application of resorcin; and (4) a case of "Ichthyosis," showing an unusual distribution, in that the palms and soles, flexures of elbows, axillae, and digital interstices were affected to the exclusion of the rest of the body.

Mr. Cotterill showed a "Recurrent Functing Sarcoma" of the shoulder which was quite inoperable, and was now accordingly treated by X-rays.

Dr. George Gibson showed microscopic specimens from a case of "Addison's Disease," demonstrating the freedom of the suprarenal bodies from tuberculosis.

Dr. Hill Buchan showed two microscopical preparations from a case of "Asthma," showing an unusual degree of eosinophilia.

Mr. Scott Skirving showed (1) a number of sterooscopic photographs of tuberculous lesions, including a series of extragenital changes of the hand, fingers, and eye. (2) The trachea and lungs of a lad, aged 15, in whom death had resulted from gangrene of the lung showing the impaction of a piece of locust bean in the left bronchus. Operative interference had been abstained from in the early stage of the case owing to the absence of serious symptoms, and in the late stage, owing to the development of septic pneumonia.

Mr. Cotterill showed (1) large "Multiform Ovarian Cyst." (2) "Hydronephrosis," due to occlusion of ureter. (3) Tumour removed from gluteal region of a child, aged 5. (4) Specimens illustrating longitudinal splitting of the internal semininal cartilage in so-called dislocation of that structure.

Mr. Caird showed specimens of strictures of the intestines illustrating his paper on ENTEROCOTOMY FOR TUBERCULOUS STRICTURE OF THE INTESTINE, a full abstract of which will be found in another column under the heading of "Original Communications."

Sir Thomas R. Fraser, the retiring president, then delivered a short valedictory address. Among the losses which the Society had sustained during the two years of his tenure of office was that caused by the death of Mr. Noel R. Wilson, of an heroic nature. His name had now been replaced on the roll by that of Sir William Turner. Of the ordinary members who had passed away special reference was made to Drs. W. B. Jaffray, Peel Ritchie, and Stewart Stirling. A résumé of the work of the past two sessions was then given, and allusion made to certain alterations in procedure—viz., the circulation of abstracts of papers prior to the meetings at which they were read, the adoption of the system of "card" specimens, and the introduction of clinical meetings at the infirmary and sick children's hospital.

The following office-bearers were elected for the current session: President, Mr. John Cheyne; vice-president, Sir Halliday Croom; councilors, Drs. E. Carmichael, T. B. Darling, W. Stewart, W. G. Sym, Underhill, Dawson Turner, Norman Walker, and Fraser; treasurer, Dr. Harvey Littlejohn; secretaries, Mr. Alexis Thomson and Dr. G. Hand; editor of "Transactions," Dr. W. Craig.

ULSTER MEDICAL SOCIETY. OPENING MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST, ON THURSDAY EVENING, NOVEMBER 3RD.

The President, Dr. John Campbell, in the Chair.

The President gave an address on the treatment of some minor gynaecological affections.

Dr. Campbell said that we were very prone to dwell
abdominal lesion of an acute nature was diagnosed, the services of the surgeon should be requisitioned, and with him should rest the decision as to the necessity of operative interference. Every practising surgeon could recall numerous instances in which valuable lives had been lost by temporising, and while the blame did not always rest on the physician in charge, there was no doubt that it was only too great a tendency to procrastinate in these cases. Now that the dangers of abdominal section had been reduced within such narrow limits, the continuation of any medicinal remedies, in cases which did not quickly respond to them, was inadvisable, and the question of operation should be boldly faced at once. The continued administration of opium in these cases was especially to be condemned, as obscuring the symptoms of the disease, and giving rise to a false sense of security. It was especially in cases of appendicitis that these questions were likely to arise, and fortunately there was now practically a consensus of opinion as to the proper mode of treatment in these cases. Unless the case were of a mild type, or unless it improved rapidly on medicinal treatment, an operation should be undertaken, and even if recovery took place without opera-
tion, it must be remembered that, in the quiescent period, if a diagnosis of appendicitis had been confidently made. In concluding his paper, Dr. Cotter referred briefly to the excellent work now being done by Freyberg and others in postoperative cases, and urged the earlier and more general adoption of the operation devised by that surgeon.

FRANCE.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Nov. 11th, 1903.

LOCOMOTOR ATAXY.

The diagnosis of locomotor ataxy in its initial stage is far from being easy, and requires a great deal of attention on the part of the medical practitioner. Professor Fournier, who is regarded as an authority on the subject, says that when the malady was confirmed the diagnosis presented but little difficulty. The locomotor troubles were so characteristic that it was sufficient to see the patient walk a few moments to recognise the nature of the disease. Not so, however, in the incipient stage; consequently it was indispensable to have recourse to the examination of certain signs, which he enumerated as follows:—The sign of Westphal, the sign of Romberg, the sign of the stairs, the sign of crossing the legs, the walk at the word of command, the sign of standing on one leg.

The sign of Westphal was known to all, and consisted in the abolition of the patellar reflex. It existed in three-fourths of the cases as a premortuary sign. Yet some persons in the normal state did not possess patellar reflex.

The sign of Romberg could be found by the following experiment:—The patient was told to stand straight like a soldier at attention and with closed eyes. In a few moments he was seen to oscillate backwards, forwards and laterally. The equilibrium being unstable, the muscular system needed a regulator, which was wanting; vision. The eye was a supplementary agent coming to the aid of a defective muscular co-ordination.

Sign of the stairs. All ataxic patients, even at the early stage of their malady, experienced considerable difficulty in descending the stairs. That exercise which was difficult, complex and dangerous required all the co-ordinating faculties of motion, revealing more than any other the imperfection of the muscular system. Ataxic patients descend the stairs slowly, holding on to the balustrade and fear to fall.
Sign of crossing the legs. An ordinary person seated, who wished to cross the legs, raised the leg simply to the height desired, and the operation was effected without hesitation. Not so with a patient suffering from locomotor ataxy. He hesitated, put his leg up with a certain vivacity, to an exaggerated height, by a kind of jerk movement, making it describe an arc of a circle larger than necessary, thus indicating a fault in the play of the muscular system.

Sign of walking at the word command. Under this denomination Professor Fournier comprised three probable experiments. In the first, the patient being seated was told to get up and walk immediately. The man would rise, but at the moment of walking he staggered and found it necessary to steady himself before going. If the patient, while walking, was told to halt, he could not stop suddenly, as he was carried away by the impetus of motion. If he were asked to turn to the right or to the left he could not obey promptly; he hesitated, and sometimes a fall was imminent.

The sign of standing on one foot, the eyes open at first and then closed, was important. The patient could not, even with the eyes open, maintain his equilibrium; he staggered, and would fall if he did not place the other foot on the ground to steady himself. Not infrequently the eyes were closed and the phenomena were much more exaggerated.

When a patient is suspected of having ataxy, all these signs should be sought for to establish the diagnosis.

**Treatment of Chancr.**

M. Barthélémy advises the following treatment in syphilitic chancres:—If the chancre is of recent date and situated on the free edge of the prepuce (of the labium in woman), excision, followed by aseptic suture, might be advised. If the sore is ulcerated and of long duration, two months for instance, and that excision was impossible, a few drops of a soluble mercurial preparation (benzoate, hiniobiode or sublimate) might be injected into the chancre. Having washed the parts with a solution of nitrate of silver, in 50, the following ointment should be applied:—

- White precipitate
- Resorcin
- Vaseline
- Lainol

The same ointment can be used for the normal chancres.

The internal treatment should consist as much as possible in mercurial injections. If these were not accepted the ordinary classical treatment should be given.

**Germany.**

**Berlin, November 10th, 1903.**

At the Gesellschaft f. innere Medizin, Hr. Westenboecker showed

**Four Interesting Cancer Cases.**

The first was that of a patient who had gastro-enteros- tomy performed in 1902. The Murphy button remained behind and could not be found, although an exploratory laparotomy was performed afterwards and the whole abdomen carefully searched.

At the autopsy it was found in the fundus of the stomach.

In the second case closure of the cervical canal of the uterus and hydrometra developed in consequence of malignant disease of the cervix. At the autopsy cauliflower growths were found over the whole mucous surface of the interior.

The third was a medullary tumour of the sternum. Bony substance was almost completely absent. Metastases were found in the liver and the cardia of the stomach. The disease was of endometriosis; the metastases must have followed the blood tracts.

In the fourth case the clinical features were chiefly central. The autopsy showed cancer of the stomach, proceeding from an ulcer, carcinomatous infiltration of the pancreas, growth of malignant masses in the branches of the portal vein, pachymeningitis hemorrhagica purulenta, leptomeningitis, thrombosis of the vein of the pia mater, and embolism of intestinal walls, carcinomatous nodules in the ilium terminale, &c. The dura was a carcinomatous mass. The bacterium coli was found in the meshes of the pia mater and in the spinal fluid.

**The Treatment of Uterine Gonorrhea of Prostitutes.**

A paper on this subject in the *Archiv f. Dermat. u. Syph.* by Dr. F. Parkidi, declares that the prospects of successful treatment of this affection are not so unfavourable as has generally been believed. His conclusions are based on 244 cases treated in Klausenburg.

In the clinic of that city the chief object of treatment is the uterus itself, and the cavity is treated actively from the commencement of the disease whenever gonococci are found in the cervix. With strict anti-syphilitic precautions, the cervix may be treated, but necessary, a syringe holding about 2 c.c.m. is passed into the cavity, and half the contents of the syringe is injected into the uterine cavity, the remainder being used for the cervix. For the past few years a 5 per cent. solution of sodium lysosinate, recommended by Professor Fabinyi, has been used, and the results have generally been made twice a week.

The preparation is made by condensation of salicylaldehyde with acetone, and it possesses the advantage that with a proved high germicide power as regards the gonococcus it has no irritating properties, and does not in any way injure the tissues. Success or non-success was determined by bacteriological examination of the secretions. Of 148 cases treated with sodium lysosinate, 111 were cured, the usual number of applications being ten; of the remaining seventeen ten were finally cured by other means, so that only seven remained uncured.

At the Surgical Congress, Hr. Riese read a paper on **Subcutaneous Injuries to the Kidneys.**

He said it was the general opinion that such injuries should be treated expectantly; they gave, however, a mortality of 30 per cent. He had collected 401 published cases, and had from them drawn the conclusion that when such injuries were surgically treated, a better result was obtained. The chief dangers from the injuries were hemorrhage, peritonitis, and suppuration. There was danger of the latter-named affection when the expectant treatment was too long persisted in, for the urine at first did no harm, and if the injuries were extensive death soon took place from hemorrhage. Suppuration could generally be avoided; hemorrhage was the chief danger, and this caused 41 per cent. of the deaths. Intra-peritoneal injuries to the kidney did not always lead to serious hemorrhage. The symptoms of it were anemia and collapse, rarely shock. The case should be treated surgically at once without worrying about shock. Patients did not bleed right off, but might remain fairly well for forty-eight hours. Secondary hemorrhage took place fourteen days afterwards. Intra-peritoneal injuries of the kidneys it was advisable to perform laparotomy, as other injuries might also be found. This alone was, however, but rarely sufficient; nephrotomy was generally necessary. The speaker had found the lumbar operation sufficient. With even free laceration tamponade and suturing
were often all that were required. Such a course could only be recommended when operation was performed early; if put off, nephrectomy was necessary.

Hr. Körte, Berlin, had treated thirty-one cases in hospital in thirteen years, of which twenty-six had recovered and five died. Nineteen isolated ruptures of the kidney had all recovered; of twelve in which there were greater complications, five had died. In fourteen cases the rupture was caused by a fall from a height, and eleven falling, and seventeen times the injury was direct. Twenty-seven cases were treated expectantly, and amongst them severe cases with free haemorrhage. Operation was postponed because the condition was aseptic and the patients were much collapsed. Laparotomy was performed in four cases; three cases recovered, amongst them a case of nephrectomy for rupture with a renal calculus; in one case in which the injuries were severe death took place. The speaker had seen movable kidney follow injuries in two cases, and once hemoglobinuria. All three cases recovered.

Hr. v. Beck, Carlsruhe, had observed twenty-two cases, in none of which was a primary operation performed. As complications, he twice saw rupture of the bladder, once rupture of the bladder, and once laceration of the ureter. All the cases were treated expectantly and all recovered, one case dying three months later of osteomyelitis. In a similar way six cases of fracture of vertebrae were treated conservatively and recovered. In two cases only an operation was performed for purulent infection; both cases recovered. He had never seen any special "shock" from rupture of the kidney; he had only seen it when complicated by rupture of the spleen. His treatment was: rest in the horizontal position, ice and ergotin.

Hr. Riese recommended early operation only in the severest cases; the milder cases should be treated expectantly.

Esophageal Dilatation.

Hr. Ellinger related the case of a lady, aged 32, who came under treatment in 1896, weighing only thirty-two kilograms. There was complete stenosis of the esophagus. Gastrostomy was performed with such excellent effect that in four months the patient's weight had increased to sixty-five kilograms. When he saw the patient a year before she was a blooming woman. Then she was suddenly taken ill with rheumatism towards the close of 1902. Then she got pleurisy, and died in April last. The autopsy revealed an idiopathic dilatation of the esophagus, a normal cardia, and the mucous membrane of the esophagus was devoid of epithelium.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 10th, 1903.

Acetic Acid Poisoning.

Prokop relates the history of a case of acetic acid poisoning that came into Professor Maixner's wards a short time ago with every local and general symptom, such as albuminuria and leucocytosis. The local effects were painfully demonstrated by the subsequent appearance of stricture in the esophagus a short time after the occurrence, necessitating the use of the sound.

Heart Failure and Tuberculosis.

Feyfar recounts heart failure as one of the premonitory symptoms of tuberculosis, which, he affirms, is often to be found in conjunction with this disease. The opposite relations that exist between phthisis and valvular disease of the left ventricle are so diverse that few give the same explanation for the combination of lesions.

Professor Maixner now affirms that the combination of these two diseases is not so uncommon as was formerly announced, particularly on the right side of the heart, which is not only the result of the phthisis in the lung, but may proceed along with the disease of the lung from the same cause. As a proof of this he produced a series of cases where healing of the lung took place, leaving in its train valvular destruction of the right cardia due to the lowered nutrition in both cases.

The progressive form of tuberculosis and cardiac failure is not so common, but this occurs more frequently in females and associated with aortic destruction. Another point he mentioned as proof of his argument, that in families where hereditary tuberculosis existed valvular disease was very frequently met with.

Arterio-Sclerosis in the Nerve Centres.

Hnátek has contributed a lengthy article to a local journal on the early diagnosis of sclerotic alterations in the arteries of the brain. These symptoms, he affirms, may be reduced to headache, vertigo, and diminution of mental activity. Unhappily the diagnosis is often obscured by degeneration of the nerve system itself, as in the neurasthenic, where no arteriosclerosis is present. In these cases the origin of the symptoms will have to guide the clinician. He cites two cases where arterio-sclerosis was typically portrayed in a tumour of the brain, which led to an erroneous diagnosis. In the second case the symptoms closely resembled bulbar changes, but were complicated with hemorrhagica purpura, which would assign it according to Faisan, to the corpus of purpura myopathique généralisé.

Leucostoc Hominis.

Hlava, in his classification of the bacilli, has some difficulty in placing Leucostoc hominis in its nosology. The microbe is usually found in the buccal cavity when any of the following diseases are present:—Angina phlegmonosa, diphtheria, follicularis, scarlatinosa morbillosa, and typhus. It is also to be found in the blood of scarlet fever, measles, and typhus patients, as well as the surface of the tonsils in infectious coryza, carious teeth and hospital dysentery. The presence of this microbe in the acute exanthematous diseases leads him to believe that it has some pathogenic property, as the pneumo and diphtheria bacilli have to pneumonia and diphteria. The leucostoc is constantly present in measles, typhus, and scarlet fever, and is probably the degenerative agent as the bacterium septicum in diphteria. He affirms that the leucostoc is not identical with the streptococcii.

Acetonuria and Typhoid.

Bernert relates his experiments of ninety-four cases of typhoid under Professor Neusser. Of this number, 11'7 per cent. were positive. This condition prevails in the febrile stage during defervescence, and sometimes long after the fever has passed off. Certain foodstuffs tend to increase this constituent.

The reduced nutrition is not the only cause, else a larger number would be affected. The presence of acetone in the urine cannot be accepted as a diagnostic symptom of the disease. It may be, however, valued as a symptom of auto-intoxication.

Autochthonous Thrombi.

Walco relates an obscure case of thrombus after the removal of a polypus from the uterus. The patient, aged 49, suffered from hereditary tuberculosis and metrorrhagia. After the removal of a polypus she was suddenly seized with meningitis cerebro-spinalis e causa ignota, associated with nephritis, which ended fatally after eight days. The post-mortem revealed throm-
basis of the perivaginal veins, emboli in the branches of the pulmonary artery, thrombi in the sinus transversi dextri, as well as the venae magnae cerebri, capsule, subsequent cedema and haemorrhage; chronic Bright's disease, with caries of remote tuberculosis at the apices of the lungs.

So many probabilities exist in this case that it would be difficult to say which was the most fatal. The nephritis may have produced the morbid alterations in the vessels, or the marasmus from long-continued loss of blood from the uterus. The para- vaginal changes in the vessels after operation may also be cited as a cause. The colour of the thrombus in the transverse sinus was more autochrome than imported.

The Operating Theatres.

ROYAL LANCASHIRE INFIRMARY.

NEPHROXYM FOR SUPPRESSION OF URINE.—Mr. STANLEY BARLING operated on a man, age 19, sent to him by Dr. Shaw, of Windermere, with the following history:—For the last five years he has suffered, almost daily, from a severe aching pain in the left loin, increased by exertion and relieved by lying on the sound side. Two years ago he was laid up in bed for a week with what seems to have been a typical attack of renal colic, accompanied by hematuria. He is not aware of having passed any calculus. The present illness began four days ago. The patient went to bed in his usual health. In the middle of the night he was awakened by intense pain in the left side of the abdomen at a point two inches above and to the inner side of the anterior iliac spine. Dr. Shaw saw him in the morning and gave him an injection of morphia. When visited in the evening he was quite comfortable. Two days afterwards the friends sent suddenly to say that the patient had passed no urine since the onset. The introduction of a catheter revealed an empty bladder, and arrangements were at once made for his removal to hospital. On admission the man looked very pale and ill. Temperature, 101° F., pulse 112. The left kidney could be felt below the costal margin, and was excessively painful on pressure. Examination of the region of the right kidney was negative. There was no urine in the bladder. Here, then, Mr. Barling said, was a case of obstructive urinuria caused by one of the following conditions:—(1) A disorganised left kidney and a recent blocking of the right ureter. Against this view was the fact that the left kidney was only slightly enlarged and, moreover, there had never been any symptoms pointing to the right side. (2) Sudden obstruction of the left ureter, the fellow-kidney at the same time ceasing to act. This is said by Ossel to occur occasionally. (3) Sudden occlusion of the left ureter, the right kidney being absent. One of the latter, he thought, seemed the more probable, and accordingly the left kidney was exposed through a lumbar incision, freed from the surrounding fat, and brought into the wound. It was slightly enlarged, but there was no marked dilatation of the pelvis, nor could any calculus be felt. A free incision along the posterior border allowed a very thorough examination to be made, but although a long probe was passed down the ureter into the bladder, nothing abnormal was discovered. The kidney was fixed to the muscular walls, and a large drainage-tube inserted into the pelvis, this being tightly packed round with gauze to check the free bleeding. The operation was performed on the 1st January, and the patient left the hospital on the 15th January. On the following morning a large quantity of urine was coming away from the wound, and on passing a catheter five ounces of bloody urine were withdrawn from the bladder. Mr. Barling declined to make a definite diagnosis, but was disposed to think that the obstruction had been caused by a small stone, which was displaced during the operation and escaped. Another possible explanation was that there was kinking of the left ureter. The right kidney was probably absent.

The patient made a good recovery, and at the end of six weeks was discharged with the nephrostomy wound healed, and passing on an average 50 ozs. of urine in the twenty-four hours, free from albumin. On two occasions subsequent to the operation the bladder was sounded, but with a negative result.

FRENCH HOSPITAL AND DISPENSARY.

MULTILOCULAR CYST OF THE MENSENTERY.—Mr. CLAYTON GREENE operated on the patient, a large fat man, who was sent into the hospital suffering, it was said, from ascites. He had been ill for fourteen days, during which time his breathing had become progressively worse. Beyond the fact that he had been an exceptionally heavy drinker nothing was known of him. Next morning the resident medical officer, medical officer to the hospital with a trocar a dull area of the abdomen, which he thought was a loculated ascitic collection. Nothing was drawn off. The man appeared to get worse after this, and Mr. Greene saw him on the same afternoon, and considered an immediate operation necessary. His pulse was 130, and his respirations forty to the minute, his aspect, &c., suggesting general peritonitis. There was nothing abnormal about his lungs. On percussing the abdomen there were irregular areas of dulness both on left and right, but the chief pain and rigidity were on the right side. Mr. Greene decided to open the abdomen in the right semilunar line, having in view the possibilities of appendicular or duodenal trouble. On opening the peritoneum it was at once evident that there was general peritonitis, the cavity being filled with a quantity of purulent fluid with a sour, faintly urinous odour. There was no lesion of duodenum or appendix to be detected. So he passed his hand across the middle line through the wound and discovered a large fluctuating swelling extending across the middle line from left to right. Mr. Greene now pointed out that owing to the distension of the abdomen it was impossible to feel this mass from the outside, a proceeding which, indeed, he attempted after feeling it from the inside. He then plunged the first wound with a sponge and opened the abdomen up freely in the middle line. It was then discovered that this fluctuating swelling was an enormous multilocular cyst. From the urinous odour Mr. Greene thought it might be kidney, but, delivering it out of the wound and closely inspecting it, he found that it was a multilocular cyst of the mesentery with two feet six inches of the small intestine stretched over it. At one point there was a puncture made with the trocar, through which a fluid similar to that in the abdominal cavity poured out. It was evident that the cyst was suppurating, so it was determined to attempt its complete removal. Puncturing it round with gauze, the operator tried to draw off some of its contents so as to lessen its size; this was impossible owing to their colloidal nature. He therefore closed the two punctures with forceps, enlarged the wound, and delivered the whole tumour. It was evident that removal of the cyst must be accompanied by resection of the intestine, as the vessels to the gut were incorporated in the tumour, which was extended up to the wall of the bowel—indeed, the muscular coat of the intestine was blended with the growth. Mr. Greene therefore clamped off the gut, secured the vessels, and removed the tumour which weighed nearly twenty pounds. He then united.
the cut intestine with three rows of sutures. The cavity of the peritoneum was then washed out with about four gallons of saline and the wounds closed, three drainage-tubes being left in at the angles. The patient's pulse on leaving the table, one hour and thirty minutes from commencement of operation, was 145 and his respirations forty-four. Mr. Greene remarked that the first point to which he would draw attention was the great danger of tapping loculated fluid in the abdomen, the source of which is unknown. Apparently there was nothing in the temperature or pulse to suggest that this cyst was suppurating, but the case, he thought, shows the great value of an exploratory incision. The cyst he looked upon as a mesenteric dermoid, formed between the layers of the dorsal alimentary mesentery. A similar case, he said, was described in the "Annals of Surgery" some years ago, operated on in New York. The case recovered, but the cyst was not suppurating. The urinous odour, he remarked, was peculiar, but there was no connection with any urinous organ. The source of the infection must be obviously the intestine, and he thought it was interesting that since the man was such a heavy drinker there was some relation between the intestinal catarrh which this produces and the infection of the cyst associated with cirrhosis of the liver.

On the patient's return to the ward he was transfused with two pints of saline. He was dressed next day, and there was a quantity of discharge; he was not sick. Two days afterwards he became very distended, and died the same evening.

Post-mortem.—Liver cirrhotic, anastomosis secure, general peritonitis.

The Medical Press and Circular.

WEDNESDAY, NOVEMBER 11, 1903.

RACE SUSCEPTIBILITY TO INFECTION.

The key to progress in the scientific world, broadly speaking, lies in the generalising of a vast number of laboriously collected and accurately investigated facts. Every now and then a master mind is enabled to imprint an indelible mark upon the pages of history by the discovery of a general law. Meanwhile, the ebb and flow of theory and speculation continue ceaselessly, and are themselves controlled in their apparently purposeless movements by unseen but immutable natural laws. In other words, abstract scientific speculation merely connotes, in the majority of instances, the existence of secrets hitherto hidden in the womb of Nature. The genius of the Anglo-Saxon is essentially practical, and has led him to the discovery of the circulation of the blood, the Baconian method of experimentation, and the triumphs of antiseptic surgery, to say nothing of other landmarks that stand out prominently in that part of the vast region of the unknown universe which has been explored by the human intellect. One of the great problems before the medical investigator is that of race susceptibility to infection. There can be little doubt that the correct estimation of the underlying conditions of race susceptibility, and of its converse, race immunity, to the inroads of infectious maladies will furnish material of the utmost value to the preventive and curative branches of practical medicine. An able essay on this subject was read at the recent meeting of the British Medical Association by Dr. R. J. M. Buchanan. The great value of his communication lies in the bird's-eye view it gives of race susceptibility throughout the nations of the world. To tuberculosis, for instance, the Gaelic and Cymric race are considered more susceptible than the Saxon and Scandinavian. Negroes, on the other hand, are very susceptible to tuberculosis, especially in countries not native to them. Cancer is said to be rife in China, while it is rare in Egypt, uncommon among negroes, but prevalent among the blond inhabitants of Norway. It is a well-known fact that small-pox is excessively fatal to people among whom it is introduced for the first time, as shown among the North American Indians, where the Mandon nation was entirely destroyed by it; and in Iceland, where in the earliest epidemic eighteen thousand out of fifty-two thousand perished. Negroes are very susceptible to sleeping sickness; other races are not so. Jews are believed to be prone to diabetes and nervous diseases; Chinese are exempt from chorea; the negro is almost exempt from yellow fever, in which the order of susceptibility runs: Scandinavian, Englishman, Southern European, creole, mulatto, negro. The unravelling of all these various conditions, apart from their general interest, is likely to have a most valuable application in modern therapeutics. The line of research that at present exercises the greatest attraction to scientific medical investigators is the discovery of preventive and curative serums and antitoxins. Clearly, the question of racial immunity or susceptibility is intimately involved in that of serumtherapy. The problem of the cure of many specific infections has been already solved in not a few instances by the beneficent hand of Nature, which has caused the life of many pathogenic micro-organisms to be limited by the autogenic production of antitoxins. In the case of a nation immune against any one particular infection it may reasonably be concluded that immunity has been acquired by the natural law of evolution. In the further struggle of mankind against the evils of environment it seems not unlikely that he himself will be able materially to hasten and extend the action of evolution as applied to susceptibility, and that he
may even hope one day to establish universal immunity against infectious diseases among mankind.

THE PSYCHOLOGY OF THE CONSUMPTIVE.

In the enthusiasm born of a hopeful industry in the application of what we may call the gross hygienic treatment of consumption there is a danger of managing cases as animals to be hardened and fastened and made sleek and rosy rather than directing them as sorrowful and oftentimes harassed human beings needing much more than open air can supply or a vigorously conducted régime sustain. In short, we are of opinion that the psychological aspects of the situation are in danger of being overlooked and in some institutions almost neglected. In the first number of the Parisian Archives de Neurologie for this year there appeared an interesting symposium on this subject, and in recent numbers of the New York Medical Journal, Dr. G. A. De Santos Saxè has dealt with the psychical relations of tuberculosis. His conclusions are of much interest and of considerable suggestive value. The consumptive usually exhibits traits of mind and of temperament that have been made use of to a large extent in fiction, although they have not received much serious study from medical men. The mental and moral degeneration only too apparent in many consumptives, leading in some instances even to criminal tendencies, is thought by many to be dependent on a toxic condition of the central nervous system, states which certainly often play an important part in the etiology of neurasthenia, psychasthenia, hysteria, and insanity. We are inclined to think that in many sanatoria the habit of life initiated and maintained by the very course of treatment is detrimental to altruistic tendencies and rich in inducements to selfishness and sins of idleness. Certainly many consumptives manifest loss of control, animal self-centring, increase of susceptibility to suggestion, emotional displays, attacks of nervous irritation, and readily show evidences of nervous and psychical fatigue. Sexual irritability, at least in some cases, seems to be raised in the early stages of the disease. There is certainly a distinct connection between tuberculosis and insanity, but as to the causal relationship we are by no means clear. The medico-legal aspects of tuberculous intoxication merit serious study. Regarding the beneficent euthanasia which in many cases silently rings down the curtain we know but little; it is perhaps mainly dependent on what we are pleased to term physical causes, but we are still in the dark when we seek to unveil the mysteries of dissolution.

THE SPECIALISM OF TO-DAY.—I.

We have already commented on Sir William Church's Address at the West London Post-Graduate College on "Medical Education and Post-Graduate Study." We return to the subject, inasmuch as the questions raised by him are of the greatest importance, whether viewed from the scientific and practical or from a purely ethical bearing. Only one inference can be drawn from his classification of present-day specialists. He divides them clearly into two classes—honourable men and dishonourable quacks; and he does not hesitate to infer that even amongst the former are to be found those whom we may fairly regard as dangerous, even though their motives be honourable, or he fears that they have lost all sense of proportion from their exclusive occupation with a limited range of subjects. This is a serious impeachement of a considerable body of the profession in whom the public reposes confidence from their very claim to a more exhaustive acquaintance with the diseases they profess to deal with, and an experience necessarily enlarged by the application of time and labour to a branch of their profession devoted to the affections of some particular organ or organs. Let us look at present day-facts. No one denies that in order to cover the whole field of study in the case of such organs as the brain, the eye, the ear, or the pelvic viscera of women, the surgeon who proposes to treat accurately, and with a skilful hand to operate upon, diseased conditions of these organs must have not only a special training outside his ordinary medical course, but that aptitude which only comes through repeated experiences of methods and technique which furnish him with that manipulative dexterity on which the success of his operation depends. And in medicine also there are departments in which the first step of an accurate diagnosis can only be made after the most precise and special study of the diseases of the parts which they embrace. Take, for example, the localisation of functional diseases of the nervous system, in which the diagnostic power of the physician must precede the operative hand of the surgeon. The same remark applies in great measure to the skin and to the kidney. Certain operations on the liver and gall-bladder, stomach, and intestines demand accurate diagnosis and an acquaintance with the minuteness of details of operative technique in the surgical procedures called for to deal with them. As much from his failures as from his successes does the surgeon acquire his power over unlooked-for complications and unforeseen difficulties. Impromptu readiness in meeting these, the outcome of an educated surgical instinct, is not the product of a day, and, as every true surgeon knows, grows from year to year as his work and experience advance. While such facts do not admit of any dispute, it is generally recognised that the educated and experienced surgeon or physician is quite competent to deal as successfully as any specialist with the great majority of diseases to which any organ of the body is subject. The eye, the ear, the brain and larynx afford the most distinct exceptions. And in medicine, while certain authorities, in consequence of more extensive research into, and their writings on, the affections of certain organs, will always secure a special pre-eminence and, consequently, more general confidence, still, the all-round cultured physician should be competent to deal with disease generally as successfully, save with such exceptions as we have mentioned, as any medical specialist. Prolongation of the course of medical study, increased facilities through
NOTES ON CURRENT TOPICS.

Nov. 11, 1903.

The German Emperor's Operation.

The German Emperor performed the operation on Sunday, the 7th instant, fell upon the world with painful and dramatic suddenness. On the day in question Professor Schmidt, the well-known Frankfort specialist, removed a polypus from the larynx of his Royal patient. The report of the microscopic examination of the growth was sent telegraphically by way of postscript to the announcement of the fact of operation. It states that "the polypus consisted of soft connective tissue, with few cells, covered by regular and sharply defined layers of scaly epithelium. One portion contained pigment granules, evidently the result of former slight hemorrhages." The polypus also contained a large number of thin-walled corpuscles. The conclusion from these facts is stated clearly and emphatically, namely, that the growth is simply "a benign connective tissue polypus." In spite of the reassuring nature of the microscopic report it is impossible to avoid a feeling of anxiety with regard to the future course of events. Family history and predisposition have to be taken into consideration in estimating the full bearings of the individual case. While, therefore, there is happily no cause for alarm as to the present welfare of the illustrious patient, we shall await somewhat anxiously the fuller report that will doubtless supplement the necessarily meagre details of the telegram. Meanwhile, it is comforting to know that His Majesty is under the care of so skilled a specialist as Professor Schmidt.

The Midhurst Sanatorium.

The opening of the new sanatorium for consumptives at Midhurst, last week, by His Majesty the King will naturally attract a good deal of public attention to the value and the requirements of institutions of that kind. Speaking generally
of the palatial building and grounds at Midhurst, it may be at once acceded that they are great in conception, great in creation, and altogether form a majestic monument of the philanthropy of the present age. At the same time, it may be doubted whether the money has been spent to the best advantage. Can anyone acquainted with the inner life of the medical profession say that a few consultant physicians are the best judges of sanatorium treatment? Can anyone, on the other hand, acquainted with the architect's profession seriously maintain that any architect sending in plans for a sanatorium would be likely to lose the opportunity for projecting an elevation of stateliness and proportions? Does anyone seriously think that the co-operation of a consulting physician and an architect would guarantee the production of the best possible plan for a sanatorium? We trow not. As someone has pointed out, the English are fond of exploiting amateurs. In the opinion of some competent authorities sanatoria for consumptives are best constructed as groups of small chalets, easily and cheaply constructed, spread over various parts of the country and open to all classes of the community. The suggestion of the formation of a colony for consumptives is worthy of careful consideration in the light of modern knowledge. It is difficult to defend the aggregation of large numbers of tuberculous patients within the walls of a huge building.

The Therapeutical Society.

The report published in our columns last week of the first meeting of the Therapeutical Society, we think, be of interest to many members of the profession. Some doubt may have existed in the minds of our readers as to whether there was any need for an addition to the numerous societies that now exist for the promotion of medical and surgical knowledge and science. Among these societies, however, there was none founded for the purpose of promoting research into the interesting and important field of new plants and their properties medically considered, that is, in their uses for the treatment of disease. As new countries are being investigated and the researches of travellers are being brought to our notice, it is well to encourage the naturalist and the botanist to give his attention to the medicinal properties of new plants and to the uses made of them by the natives of previously unknown regions. This particular line of study does not belong strictly to botany, chemistry or pharmacy, and can be engaged in only by members of the medical profession. When a traveller returns now with the results of researches of the nature referred to, he will find in the Therapeutical Society the simplest means of communicating them to the profession, and we are glad to see that the Society of Apothecaries is giving its support to a branch of medical science which most certainly and appropriately comes within its functions. In electing Sir T. Thiselton Dyer as its president, great respect is shown by the Society to botanical science, and, as Sir T. Dyer is a member of the medical profession, the therapeutical value of the work carried on by it will not be disregarded.

Non-Notification of Infectious Diseases by Medical Men.

The failure to notify infectious diseases may bring most undesirable consequences upon the head of the defaulting medical man. During the past week that fact has been emphasised by the prosecution of two practitioners for that offence. In the first case a Ravensthorpe medical man was summoned for non-notification of three small-pox cases. It appeared that on September 2nd he attended a child suffering from what he regarded as chicken-pox. A second child was later infected and he made the same diagnosis. The mother took the disease and it was not until September 21st that he casually informed the Sanitary Inspector that he thought there was a case of small-pox in a certain house in the district. The Medical Officer of Health, who was not officially notified, found the patients to be suffering from small-pox and is reported to have said no medical man could have mistaken it for chicken-pox. The defence was that no proof had been offered that the defendant knew the disease was small-pox, and the case was dismissed on that ground. The second prosecution was in Birmingham, where a medical man was called to a patient suffering from scarlet fever on or about July 19th, but who did not give notice to the authorities until six or seven weeks later. Defendant was fined £2 and costs. It seems almost incredible that medical men could under any conceivable circumstances allow themselves to run the risk of so much public exposure and injury to pocket and reputation by the omission to fulfil what is simply a lawful and bounden professional duty.

The So-called New Cancer Cure.

The public Press has of late years devoted a good deal of attention and misdirected energy to the discussion of medical matters. In this way the Röntgen rays, the light cure, the crusade against consumption, and the cure of cancer have again and again furnished the foundation for more or less sensational and flamboyant journalistic treatment. Last week a semblance of novelty was thrown round the somewhat worn and derelict subject of cancer. The starting-point of the latest sensation was a lecture recently delivered before the Abernethian Society. In the course of his remarks the lecturer detailed the observations of Dr. Otto Schmidt, of Cologne, who claimed to have isolated the "cancer parasite," and to have produced an antagonistic serum capable of destroying the cancer cells. The attitude of scientific medical men will naturally be one of extreme caution with regard to statements of that kind. False hopes have been raised only too often by optimistic and self-deluding scientists. No cancer parasite has been hitherto found, but if Dr. Schmidt has succeeded in that direction he will deserve the gratitude of mankind. Some years ago, Dr. Russell, of Edinburgh, discovered certain "bodies" which
were supposed by some observers to be the cause of some forms of malignant disease. That theory, however, has never been established, any more than the further theory that cancer is a parasitic disease. To claim cure by a serum that destroys the cancer parasite is not only premature, but is likely to do great harm to the public by exciting false hopes. Why do not lay editors confirm or contradict such worthless rumours, by referring them to competent medical authorities before disfiguring their columns with such unworthy matter?

The Rejections at the Fellowship Examinations of the Royal College of Surgeons, England.

The Fellowship diploma of the Royal College of Surgeons, England, is not only one of high academic distinction, but one, also, which adds greatly to the professional value of a surgeon's services. This is not always the case so far as academic degrees and diplomas are concerned. It does not, of course, necessarily follow that a man holding high distinctions, academically, is a good man in a practical sense. On the other hand, a Fellowship diploma of the nature of that of the Royal College of Surgeons carries with it the *imprimatur* of a practical man. None save those who can combine sound scientific surgical knowledge with the practical faculty of a surgeon can hope to attain to this distinction. That this case may perhaps be judged by reference to the exceedingly high percentage of rejections at the two Fellowship examinations. According to the latest returns for the First Fellowship there were in November, 1902, and May, 1903, 238 candidates; inclusive of this number, however, only 87 succeeded in satisfying the examiners, that is to say, no less than 63 per cent. were referred for further professional studies. Then for the Second or Final examination, held during the same months, there were 113 candidates; of these 58 only passed—in other words, 48 per cent. were rejected. These high percentages of rejections are noteworthy, inasmuch as they certainly seem to indicate the intention of the College authorities to maintain and to exact an exceptional standard for anatomy in these professional examinations. In further-proof thereof even demonstrators of anatomy in the metropolitan medical schools have been known to present themselves for the First examination and to have been referred. Under such circumstances it is not surprising that other candidates should not infrequently fail whose opportunities for satisfying the examiners are less favourable. Meanwhile, we must confess agreement with those who hold that the standard of the examinations should be maintained; the tradition has existed for many years that even the best men may fail, and, as a matter of fact, any candidate may consider himself lucky who surmounts both tests without a mishap. The general rule is for failure to attend on the first attempts at both of the examinations, and there are probably few Fellows who have not had to endure the pangs of a rejection. It used to be said of one distinguished examiner, a high official at the College a quarter of a century ago, that having no time as a surgeon to keep pace with the new physiology of the period he contented himself with reading and learning ten pages of "Hermann's Physiology," and of examining the candidate therewith. By this means, no doubt, many rejections could be accounted for, since in those days the new physiology was as little known to the candidates as it was to the examiners.

Traumatism and Transposition of Viscera.

There are many errors of development which, so long as they do not involve any serious structural or postural change in the organ or tissue concerned, are absolutely without risk to the individual in whom they occur. The simplest form of transposition of the viscera, namely, that in which the thoracic and abdominal organs are merely reversed as to the side on which they are normally found, is frequently discovered accidentally during the course of a medical examination. When disease occurs in a transposed viscus, especially if such malposition happens to be more than a simple reversion, the diagnosis of the condition is often rendered exceedingly obscure. Some of the rare forms of internal hernia, such as strangulation of a loop of small intestine which has been prolapsed through a congenital aperture in the diaphragm, must be included in this category. In a similar way, the effects of injury, either from direct or indirect violence, upon misplaced organs are often very difficult to gauge accurately. The recent death of an attendant at the Holloway Sanatorium two days after being "charged" at football shows the almost impossibility of correctly interpreting the symptoms in these cases. The post-mortem appearances revealed the fact that the chief abdominal organs were situated in the thorax, having entered thither through an opening in the diaphragm of congenital origin. The heart was thus forced upwards and to the right, and the left lung was very small and contracted. Though it was stated at the inquest that the man's death was not in any way due to external violence, yet it will probably be admitted that, if such a condition could have been determined beforehand, exercise of any kind involving sudden strain or jarring would be most undesirable. Football is now made the scapegoat for so many evils which would have equally occurred had it not been played that we are glad to see that the game was exonerated in the present instance.

The Risks of Cocaine.

The great value of cocaine as a local anaesthetic is sometimes counterbalanced, in susceptible individuals, by its depressing action upon the vascular system, which may produce alarming, though happily not often fatal, results. In common with most drug idiosyncrasies it is impossible to foretell by examination of the patient how he or she will react to its administration—hence, in the use of such agents the thought of their toxic effects should ever be borne in mind. Considering how frequently cocaine is applied to the gums in dental practice it is surprising how seldom one
hears of any untoward effects resulting from its use. The case which appeared recently before the Gloucester County Court has, therefore, a special interest, not only to dental but to all other medical practitioners. A man suffering from toothache went to consult the defendant, a dentist, who, it is stated, did not advise immediate extraction, but stopped the tooth with a preparation of cocaine. When the plaintiff left the house he felt giddy and was seized with a sense of numbness in the limbs. He was conveyed home, where he was said to have been ill for six months afterwards, and on that account sued the dentist for loss of time and personal injuries. The defence was that there was a considerable nervous element in the case, and that the illness was not due entirely to the cocaine. After a prolonged hearing the jury were unable to agree and were therefore discharged. This incident serves to show that yet one more risk must be added to those already encountered by all classes of practitioners in their daily work, even when this is done in the best interests of their patients. If individual peculiarities are to be made the basis for legal proceedings we may soon expect antenatal changes to figure as the ground for some action at law.

**Syphilis and Chorea.**

The association of syphilis with chorea is one which has received comparatively scant attention on the part of physicians, but the connection of the ordinary Sydenham’s chorea of childhood with the disease is far less definite, and the two affections have not been thought to bear any special relationship one to the other. A few cases of congenital syphilis in which chorea has supervened have been reported, but it is very rare for acquired syphilis to precede an attack of chorea. Dr. Harrison Mettler, of Chicago, writing in the *American Journal of the Medical Sciences*, believes that it is quite possible for the syphilitic tox in to cause disturbances of nutrition in the cortical cells and so produce chorea, especially in those varieties of the disease due to irritation dependent upon gross organic lesions of the brain. Attention is called to the existence of two forms of syphilitic chorea, the focal and the generalised, and the inference is drawn that these are expressive of a change in the functional activity of the motor neurons. That this may be the case when there is distinct evidence of syphilis will be acknowledged, but the term “syphilitic chorea” will hardly find favour with those who have long been accustomed to regard the disease as a specific rheumatic affection of the nervous system. In actual practice it is very seldom observed that the choreic child shows signs of congenital syphilis, and the presence of the acquired disease is so rare as to be practically unknown. However, the possibility of the influence of syphilis in the production or aggravation of chorea should lead to careful investigation in those cases in which rheumatism can be absolutely excluded, and should it exist, vigorous treatment must be adopted side by side with other anti-choreic remedies.

**Ankylostomiasis in Cornwall.**

The appearance of ankylostomiasis among the miners of Cornwall has caused, not unreasonably, considerable alarm and apprehension among the whole community who earn their living underground. The disease has been known under various names for a century and a half, and has been described in such widely-distant countries as Peru, the West Indies, Egypt, Gambia, Zanzibar, and India, besides various parts of Europe. The credit of discovering the causal parasite rests with Dubini of Milan, who found it *post-mortem* in a large number of bodies. His work did not receive universal recognition at the time (1843), and it is really to Bilharz and Griesinger that we owe our present knowledge of ankylostomiasis duodenale. Their work has been abundantly confirmed since, notably by the Italian and Swiss physicians who had to deal with the outbreak of ankylostomiasis among the workers in the St. Gothard tunnel. The disease is due, of course, to the introduction of the larva of ankylostoma into the intestine, and this occurs either through drinking water from warm and marshy places, where the eggs are germinating, or by contamination of articles of food by fingers soiled from similar sources. The Home Secretary has taken prompt and commendable action by sending Dr. Haldane to Westphalia to learn how the disease is dealt with there, but in the meantime if proper precautions with regard to water and food be observed by the miners, the risk of infection will be reduced almost to nil.

**A Two-Edged Sword.**

Whilst many interesting accounts of X-ray treatment in malignant disease continue to appear in the various journals, we note that the influence of the rays is far from well understood yet in relation to these conditions. Two disastrous results have occurred in those who have met with previous accidents from the rays. A tube-maker, who had an X-ray cicatrix on the forearm, has developed carcinoma in the scar, and a patient with an X-ray ulcer has had to have the limb amputated, for the ulcer was found to have become epitheliomatous. A measure that can (apparently) both remove cancer and cause it is one that may well give one reason for hesitation before employing it, and we trust that for the relief of those conditions in which it seems beneficial it may continue to be used without any of these *contretemps*. There is no doubt that the rays are capable of effecting profound nutritional disturbance in the tissues, and we hope that the nature of the change may be speedily ascertained. It would be a thousand pities if a measure so full of promise had to be abandoned because of the possibility of its causing such grave results.

**Regenerating Expired Air.**

A striking instance of Gallic ingenuity is to be found in the pages of *La Revue Minéraleurgique*. This is no less than an invention whereby expired air may be purified and rendered fit for respiration, and its object is to secure for firemen, sewer-
workers, and miners a means whereby they can remain in a vitiated atmosphere for a considerable time without requiring fresh air. The clever device by which this is accomplished consists of a diver's helmet with sight-holes, to which is attached the regenerating case. The air is drawn into this latter by a clock-work fan and there meets with water in which dioxide of sodium is dissolved. The carbonic acid in the vitiated air combines with the dioxide of sodium, and oxygen is evolved to take its place in the air that passes back into the helmet. The renewed air is warm as the result of the chemical action, so a refrigerating contrivance worked by methyl chloride is introduced to cool it. If the invention be all, or even half, what is claimed for it by the inventors, it should be a valuable addition to fire-brigade appliances. Death results far more frequently from asphyxia and carbonic acid poisoning, produced by the products of combustion of a fire, than from actual burning, and with a helmet of the type described one of the greatest difficulties of rescue-work would be obviated.

Herpes.

An attack of "shingles" is generally accorded scant recognition. Its diagnosis is generally straightforward; it runs its course with little respect to treatment; and the principal symptoms that demand attention are irritation and pain. The latter is certainly very severe at times. In the American Journal of the Medical Sciences Dr. Howard addresses himself to the question of the pathology of the condition, and his work tends to bring into line the two manifestations that we recognise clinically as herpes zoster and herpes labialis. The former he considers from his own work and that of others to be due to hemorrhage in the posterior spinal ganglia, whilst herpes labialis is associated with apoplexy of the Gasserian ganglion. He divides these groups of herpes from those occurring in connection with such poisons as arsenic and carbon-monoxide, which again have to be distinguished from those occurring in the acute specifica. All, however, have the same fundamental pathological lesion. The common forms of herpes that accompany nasal catarrh and gastric disturbance he does not classify, as they have not yet been sufficiently investigated. It seems unlikely that all these can be unified, for herpes most certainly follows direct local irritation in some cases. For example, who has not seen herpes labialis follow a visit to the dentist?

The Local Government Board and Medical Work.

The Report of the medical officer of the Local Government Board for the year 1901-02, published a few weeks ago, contains so many matters of great interest to the profession that we find considerable difficulty in endeavouring to deal with it in the space at our disposal. The activities of the medical officer's staff are by no means confined to the mere tabulation of sanitary statistics, important as such work is, but, securely hidden in appendices, we find papers of the greatest interest on purely scientific subjects. Indeed, our pleasure in reading such reports as those of Dr. Klein on, for example, the diphtheria bacillus and organisms liable to be confounded therewith, and on the bearings of agglutination to specificity, is only alloyed by the fact that, owing to their secluded position at the end of a "blue-book" they may not receive from men of science the full consideration they deserve. To medical officers of health, and, indeed, to all, lay and medical, interested in sanitary science, the reports of the various inspectors in regard to local outbreaks of disease into which they were sent to inquire are of great value. They are, in fact, models of how such reports should be done. No pertinent circumstance—sociological, bacteriological, sentimental—seems to have escaped the notice of the investigators, and the reports on, for instance, scarlatina at Weymouth and enteric fever at Whitehaven (we mention these simply as being the fullest) are masterpieces in their exactitude and completeness. The statistics comprised in the volume have for the most part reference to vaccination. It is satisfactory to note that taking the country as a whole the rate of abstinence from vaccination has been steadily diminishing during the five years in which the present Act has been in force—this, in spite of conscientious objectors. London, however, lags far behind the rest of the country, and this condition is due, not to conscientious objectors, but to negligence on the part of the responsible authorities. We have said enough to show that we regard the report as one of value and interest. Its compilation reflects credit on the medical officer, Mr. W. H. Power, who is fulfilling his duties with a vigour and ability equal to that of his distinguished predecessor.

The Manufacture of Matches.

At the last meeting of the Society of Chemical Industry an interesting discussion took place on the manufacture of matches. It was initiated by Mr. Muir, who described experiments he made some years ago with a new preparation of phosphorus, which he found made good matches. His preparation was a scarlet sulphide of phosphorus. It is described as a new chemically active and physiologically inert variety of red phosphorus. It is made by dissolving ordinary phosphorus in phosphorus tribromide and heating the 10 per cent. solution to the boiling-point for several hours. It makes a good striking match compound, and its use is not attended with the risk of producing phosphorus necrosis of the bones, especially of the lower jaw, which were so common in the early decades of the nineteenth century. Soon after Preschel introduced his igniting phosphorus composition: Maxillary necrosis became one of the commonest forms of disease on the Continent, and years later in England, where the phosphorus match displaced Mr. Walker's "Congreves" of sulphide of antimony and chlorate of potassium. The workers in match factories continued to suffer from the effects of the fumes until 1855, when
Bryant and May adopted the red or amorphous phosphorus, which is physiologically inactive, in their works. But the public still continued to demand a match that could be struck on any rough surface, and this, it is claimed, can be done by the scarlet variety of the element. If so, and that the product can be produced at a cost to allow of its commercial use, it is not unreasonable to conclude that necrosis as a result of the use of phosphorus in the manufacture of matches will cease to exist.

Open-Air Treatment for the Inebriate.

The ardent teetotaller has for long condemned the policy of the "open door" as regards the "drink-shop," but he has been slow to recognise the beneficial influence of "open-air" treatment in the restoration of the alcoholic. Moral efforts and secret cures both have their enthusiastic supporters, and it must be admitted that good influences often fail, while bad measures sometimes succeed. But no serious student of inebriety can fail to discover that behind this morbid state are physical disturbances and psychological derangements which call for rectification before "cure" can be secured. In the restoration of the inebriate a resort to hygienic measures is of the first importance. The life of the inebriate is essentially artificial. His greatest hope lies in a return to natural methods of living. The establishment of industrial farm colonies where an outdoor life can be assured, suitable work provided, and a healthy environment maintained is a step in the rational treatment of inebriety eminently scientific and likely to prove particularly satisfactory. The majority of retreats for the inebriate in this country are far from satisfactory, and we consider further legislation will have to be provided if the interests of this unfortunate class of patients is to be adequately protected.

Medical Men and Publicity.

In spite of every care which may be taken to prevent such an occurrence, considerable annoyance and inconvenience are frequently caused to medical men owing to the unpermitted use of their names in the public Press in connection with their treatment of patients. It is quite a common thing to read in the "Society" or "Personal" column of many newspapers announcements to the effect that "Sir William Jones has been successfully operated upon by Mr. Smith for appendicitis," or that "Dr. Clark has advised that Madame Louise should cancel all her engagements for the present." Such statements as these do not necessarily reflect any particular credit upon the practitioner concerned, while they certainly tend to compromise his position as a member of a dignified and learned profession. It is quite another matter when a member of the Royal Family is taken ill. The public have then a right to know who is in charge of the case, upon the treatment of which the future of an empire may be at issue. The bulletins which are published upon such occasions are read by millions of eager eyes, and the readers themselves place great importance not only upon the words contained therein, but also upon the signatures appended thereto. The majority of editors are fully cognisant of the principles of medical etiquette, and are very ready to withdraw anything appearing in their papers which might be to the detriment of any practitioner, and to do all in their power to prevent its recurrence. Seeing the need for an authoritative statement on the matter which would at the same time voice the general opinion of the profession, the Council of the British Medical Association have adopted the following very wise resolution, namely, "That a circular letter be sent to the principal London newspapers (and we might say also provincial) newspapers, deprecating the mention in paragraphs relating to the ill-health of persons, other than members of the Royal Family, of the names of the medical men in attendance."

The Pupil in Diagnosis.

The somewhat intricate nervous mechanism by which the movements of the pupil are controlled in health is often a subject of difficulty to the student of physiology. The vascular connections of the iris are also of an arrangement peculiar to that body, and disturbances of the blood supply are quite as apt to give rise to changes in the size or mobility of the pupil as are disorders of its nervous fibres or centres. Our knowledge of the means by which these alterations are brought about has been derived, in the first place, from the laboratory, and the names of Petit, Valentin, Budge, Waller and Brown-Séquard will ever be remembered for their work in this domain of physiology. From the clinical side, the shape of the pupil in disease has always furnished an attractive field for observation and research. The classical pupillary symptom met with in locomotor ataxy, the Argyll-Robertson pupil, is one of the most important and universally known morbid conditions of that affection. In a paper read before the Canadian Medical Association in August, by Dr. J. T. Duncan, the necessity is urged for carefully examining the patient for tabes dorsalis in any case of abnormality of the pupils, as early evidence of the disease may often thus be detected before the appearance of any other symptom. The explanation which ascribes the anisocoria or inequality of the pupils occurring in cases of thoracic aneurysm to interference with the sympathetic nerve has been regarded as unsatisfactory, and Drs. Cecil Wall and Ainsley Walker have shown (a) that alterations in vascular conditions can and do produce changes in the size of the pupils. Inequalities of blood pressure in the ophthalmic arteries resulting from abnormal vascular conditions are often responsible for inequality of the pupils. For this statement, both clinical and experimental evidence is forthcoming.

The next session of the General Medical Council will open on Tuesday, the 24th inst., under the Presidency of Sir Wm. Turner, K.C.B.

(a) Lancet, July 13th, 1902.
The Mastership of the Rotunda Hospital.
The election to the important post of Master of the Rotunda Hospital was held on Friday last at the Hospital, with the result that Dr. E. Hastings Tweedy, Gynaecologist to Dr. Steevens' Hospital, was appointed by a very large majority. Dr. Tweedy held the post of Assistant to the Master of the Hospital from 1892 to 1895, and on leaving the Rotunda was appointed to Dr. Steevens' Hospital. In former days he was a most successful teacher, and he will undoubtedly attract a large class to the Rotunda Hospital, of which he will prove a strong and capable Master.

PERSONAL.

Dr. Fred. Kiud, late Master of the Coombe Hospital, has been appointed Gynaecologist to the Meath Hospital.

Dr. H. Pringle has been elected a Surgeon to Mercer's Hospital, in succession to Dr. H. Croly, who has resigned.

Mr. J. G. Craggs, who has acted as Honorary Secretary of King Edward's Hospital Fund since its foundation, has received the honour of Knighthood from his Majesty.

Dr. Robert Bell, D.Sc., LL.D., F.R.S., Acting Director of the Department of Geological Survey, Canada, has been appointed a Companion of the Imperial Service Order.

The appointment has been officially announced of Captain H. V. Pryne, of the Royal Army Medical Corps, as specialist in ophthalmology in the Thames and Woolwich districts.

The Council of King's College, London, has just elected Dr. C. S. Myers to the lectureship on experimental psychology at the College rendered vacant by the resignation of Dr. W. G. Smith.

We understand that Dr. Charles J. Martin, F.R.S., has now entered upon his duties as Director of the Lister Institute of Preventive Medicine, and that in future the administrative work of the Institute will be under his control.

The annual dinner of the staff and past and present students and friends of the Royal Dental Hospital of London will take place on Saturday, November 21st, in the Whitehall Rooms of the Hotel Métropole, under the presidency of Mr. F. J. Bennett, M.R.C.S., L.D.S., Eng.

Professor George Pirie will preside over the November dinner of the Aberdeen University Club in London, to be held at the Trocadero Restaurant, Shaftesbury Avenue, W., on Wednesday, November 18th, at 7 p.m.

Dr. Edmund F. Trevilyan, of Leeds, delivered the Bradshaw Lecture at the Royal College of Physicians, Pall Mall East, on November 5th. Sir W. S. Church, the president of the College, was in the chair. Dr. Trevilyan's subject was "Some Observations in Tuberculosis of the Nervous System," based upon 114 cases which had been treated in the Leeds Hospital.

Mr. Percy Dunn, F.R.C.S., the well-known ophthalmic surgeon, has recently retired from the editorship of the West London Ophtholomical Society's Journal. The idea of founding the journal originated with Dr. Symons Eccles, the late president of the Society. It was carried out by Mr. Dunn, who, in the course of a few years, achieved phenomenal success in what is admittedly a difficult task—namely, the organisation of a successful medical journal.

The will of the late Mr. Forster Green has just been made public. Among many other legacies to medical charities he leaves £500 to the Samaritan Hospital, Belfast. After the death of his widow the trustees are empowered to pay £10,000 to the Forster Green Hospital for Consumption and Chest Diseases as an endowment to extend the benefits of its treatment.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

[From our Special Correspondent.]

BELFAST.

Belfast Corporation.—At the quarterly meeting of this body on the 3rd inst., several matters of medical interest were discussed. An elaborate report on the flooding of the city was presented to the meeting, from which it appears that nothing has yet been done to prevent a repetition of the great flood of September, 1902, and, indeed, the rainfall of Sunday, October 25th, would have produced quite as bad a state of things if it had continued a few hours longer. About an inch fell in four hours. A new city surveyor is just about to enter on his duties, and one of the first and most important will be to deal with this question. Two important resolutions were discussed relating to public health. One was: "That the Council authorise the Public Health Committee to advertise for suitable sites, not exceeding ten acres, for the erection of shelters for the use of consumptive patients." The other resolution was to approve of a memorandum of an agreement made between certain members of the Public Health Committee and of the Committee of the Forster Green Hospital for Consumption. This runs as follows:—"The committee of the Forster Green Hospital to erect the buildings necessary to accommodate seventy patients, to be sent by the Corporation, in consideration of an annual payment of £200 a year for seven years, and if the Corporation determine to continue the arrangement, they to be at liberty to renew it for a further period of seven years, for an annual payment of a sum to be decided upon by the City Surveyor and an architect nominated by the hospital authorities, to cover the upkeep of that portion of the buildings allotted to Corporation patients. The Corporation to pay 25s. per week for each bed for the maintenance, medical attendance, nursing, and all other expenses incidental to the treatment of the patients sent to the hospital by them. The admittance of all patients to be subject to the existing rates of the hospital, and the Corporation to have a representation of five members on the committee of management. The foregoing arrangements to be subject to the approval of the Public Health Committee, the Committee of the Hospital, the Corporation, and the Local Government Board." As will be seen, this is a most important new departure, and one of deep interest to the whole medical profession of the northern province, and it is therefore greatly to be regretted that on the large Committee of the Hospital there is only one representative of the medical staff. The plan may work excellently, but it requires no great foresight to see numerous difficulties in its way, which any medical man could point out to the Committee. Of these two resolutions the first was passed, and the second referred back to the Public Health Committee.
for further discussion. A lengthy but singularly barren discussion on the typhoid question followed.

Correspondence.

OPERATIONS FOR RECURRENT DISEASE OF THE FRONTAL SINUS.

To the Editor of The Medical Press and Circular.

Sir,—In Mr. Mayo Collier's case of recurrent disease of the frontal sinus, in your issue of November 4th, p. 507, a very important point in the treatment of disease of the frontal sinus receives notice, namely, the influence of the condition of the turbinate bodies and other structures in diminishing the lumen of the nasal meatus. In this particular instance, where in a third time an operation appeared to be called for, he "removed the anterior end of the middle turbinate body, and with a curette took away a mass of granulations from the opening of the infundibulum; a small curette could now be introduced into the frontal sinus, which took away a quantity of thick, creamy pus." He felt sure that in this case the larger operation of opening the frontal sinus again from above was not requisite. I beg to recommend the removal of the anterior end of the middle turbinal as a preliminary measure in all cases of frontal sinus empyema. I would, in addition, draw attention more definitely to the frequency with which, in such cases, there is present a hypertrophic condition of the tissues covering the uncinate process of the ethmoid bone and forming the anterior lip of the hiatus semi-lunar; this is sometimes so large as to simulate the turbinate body, from which, however, it can be distinguished by means of the probe. When hypertrophied it forms a kind of scoop in which pus from the frontals or maxillary sinuses may accumulate. At the same time, it may, from its increase in size, act as an obstacle to the exit of normal and abnormal secretions from the sinuses. This "rhinological" treatment of the empyema of the sinuses will, I am sure, commend itself to the general as well as to the "special" surgeon.

I am, yours truly,

Dundas Grant.

"THE DAILY ROUND FOR THE COMPLEXION."

To the Editor of The Medical Press and Circular.

Sir,—Among a column or so of advice, good, bad, and indifferent, printed under the above heading in the first number of your lively new contemporary, the Daily Mirror, the following passage holds a place: 

"Pale women may obtain a colloid where washing the face with a hot gruel of oatmeal and water, afterwards sponging it with pure alcohol"! If any readers should follow this advice, will the editor of the paper render himself liable to an action for damages to compensate for the suffering and injury certain to be inflicted? The Daily Mirror is introduced as a paper for women with lofty promises. If it proposes to publish "medical" columns, will it not be well for the proprietor, in order to protect himself from the consequence of such a lapsus, to engage a medical editor, preferably a

Lady Doctor.

November 2nd, 1903.

[The so-called medical columns of not a few of the journals for women are calculated to inflict endless injury and suffering among their readers. To puff quack and proprietary articles is to recommend quacks and charlatans, and to advise the following of fantastic medicines, whilst treating spread disaster with ample and universal hand. In our opinion the publication of such false and spurious medical advice should be made a punishable offence.—Ed.]

THE MIDHURST SANATORIUM.

To the Editor of The Medical Press and Circular.

Sir,—The opening of the new sanatorium at Midhurst suggests to my mind the question whether the nation has, so to speak, got its money's worth. That the sum given by Sir Ernest Cassel to his Majesty has been expended with the very best motives and under the best obtainable advice can hardly be doubted. The result, however, is a palace on the Kentish hills, so organised that it will be available only to patients who can afford to pay £1 a week or more for their treatment. Was that the intention of Sir Ernest Cassel? Anyway, I myself do not see if well-to-do patients ought to be treated for free, why they should not provide the funds for a sanatorium out of their own pockets. The urgent need of the present day is to weed out of our poor population the consumptives who form the centres of constant infection to their families and to build palaces for those who are well-to-do, and who are clearly less likely to be dangerous distributors of infection.

As a medical practitioner of long standing I must emphatically protest against the congregation of consumptives under one big roof. A scattered cottage or hut system is the ideal, somewhat on the plan of a military camp.

Yours truly,

L.R.C.S.

Reading, November 7th, 1903.

THE PROVISION OF DENTAL RELIEF.

To the Editor of The Medical Press and Circular.

Sir,—With reference to your admirable leader under the above heading this week, I would like to point out that the question of dental relief in London and most large towns might be to some extent met by the establishment of a properly equipped dental department in every general hospital. At present Guy's is the only hospital in the Kingdom possessing such a department. Forty thousand pounds were spent on the site and building of the Dental Hospital of London. This sum would have sufficed to provide accommodation, equipment, and the nucleus of an endowment for a complete dental service in half a dozen hospitals at different parts of the Metropolis. This would have been much better for the poor, much better for the dental profession, and much better for students of medicine, who would have been provided with an opportunity of seeing the practice of conservative dentistry, of learning dental hygiene and understanding the measures available for preventing or relieving crowded jaws, one of the main predisposing causes of dental decay.

We possess no scientific data to prove that dental decay is more common now than in previous generations. It is only within recent years that any systematic attempt has been made to inquire into the condition of the teeth in masses of the population. Examination of the teeth of school children has latterly been carried out sufficiently widely to prove the almost universal existence of caries; but no earlier statistics exist for purposes of comparison. There is gradual increase in size of the jaw bones and teeth from the gorilla through savage and primitive races to those of the highest civilised type; and there is good reason to believe that the teeth also are of relatively inferior structure. Innate structural weakness and defects in the enamel, and crowding and irregularity of the teeth due to smallness of the maxillae, form the two chief predisposing causes of decay; and in so far as these are the results of civilisation, to civilisation may be ascribed the causation of dental decay.

I am, Sir, yours truly,

A Consulting Dental Surgeon.

Lectures at the Royal College of Surgeons, England.

To-day (Wednesday) and on Friday next, at 5 p.m., Professor Andrew Melville Paterson will conclude his course of lectures on "The Development and Morphology of the Sternum." On November 16th, at the same hour, Professor Arthur Robinson will commence a course of three lectures on "The Early Stages in the Development of Mammalian Ova and the Formation of the Placenta in different Groups of Mammals." All members of the profession and medical students are admitted to these courses on presentation of their address cards.

THE WYRLEY CATTLE-MAIMING OUTRAGES.

We feel it a public duty to call urgent attention to the cattle-maiming case at Wyrley.

A young Birmingham solicitor lies in prison condemned to penal servitude as the perpetrator of a number of senseless and absolutely brutal and wanton outrages on cattle. The evidence on which he has been convicted was purely circumstantial, and, as such, open to the fallacies that must necessarily attend that kind of evidence.

During his imprisonment and while awaiting trial a further cattle-maiming outrage was committed in Wyrley, the village where accused lived. Since his conviction still other cattle have been maimed and killed. On this ground alone, therefore, we submit that his sentence demands revision.

But if an educated solicitor killed cattle in the senseless and purposeless manner under which the Wyrley outrages were committed, we submit hesitatingly he was, on conviction, fitted for a lunatic asylum rather than a prison.

There has been a grave miscarriage of justice, and we appeal to the Home Office for immediate action by way of revision of the sentence in this case.

If necessary, we are prepared to nominate the necessary scientific body of investigation as to the state of mind of a cattle-maimer of the kind involved on the assumption of the recent sentence.

On the grounds of probability, of evidence, of scientific assumption, and of everyday commonsense judgment, we maintain that the prisoner convicted of cattle-maiming at Wyrley should be forthwith either be made the subject of an inquiry de lunatico or be granted a Royal Pardon.

To take any other attitude appears to us to court a state of chaos in English justice.

Obituary.

FRAY ORMROD, L.R.C.P., L.M., L.R.C.S.Edin.

We regret to announce the death of Fray Ormrod, of Hindley, Workington, Cumberland, at the age of sixty-four from apoplexy. Mr. Ormrod was born in 1843, of an old and well-known Lancashire family, a branch of which settled near Bolton over 200 years ago. He began the study of medicine at Belfast, but afterwards went to Glasgow, and finally took the diplomas of L.R.C.P., L.R.C.S., at Edinburgh. Soon afterwards he settled in the district of Workington. Mr. Ormrod was beloved by his patients and esteemed and respected by his townfolk, but his name became known to the outside world at the time of the disastrous explosion at St. Helens colliery in 1888. As surgeon to the colliery he volunteered to be let down the shaft to explore the tunnels and to give assistance upon the spot to the survivors among the injured. The devotion to duty which he displayed upon this occasion attracted the attention of the British Medical Association, and it was decided by the Council to award him a gold medal. This was presented to him by Sir William Gardiner at the annual meeting of the Association at Glasgow in the same year.

DR. RICHARD F. B. HALPIN.

The lamented death of Dr. Richard F. B. Halpin occurred at his residence, Ferrybank, Arklow, on October 19th, of pneumonia, and the early part of formication. He became a member of the Royal College of Surgeons in 1859, and afterwards a licentiate of the Royal College of Physicians, Ireland. He was for some time house physician to the Hospital for Diseases of the Chest, and afterwards surgeon in the service of the Eastern Telegraph Company. In 1885 he settled down in his native town of Arklow, succeeding to the extensive practice of his father, the late Dr. Stopford Halpin, in addition to holding many public appointments, including that of physician to Arklow Fever Hospital, of surgeon and agent to H.M. Coastguards, and of medical attendant to the Royal Irish Constabulary. Dr. Halpin leaves behind him three children and a widowed mother, with whom sincere sympathy is felt. His loss will be felt through an usually wide circle of personal friends of all classes of society in County Wicklow.

Literature.

MCKERRON ON PREGNANCY WITH OVARIAN TUMOUR. (a)

We congratulate Dr. McKerron on being the first to publish in English a systematic monograph dealing with the important subject of ovarian tumours in their connection with childbirth. The present volume is most acceptably the result of a paper on the same subject which the author read in 1897 before the Obstetrical Society of London, and is deserving of close perusal. The book is divided into three parts: "Pregnancy with Ovarian Tumour," "Labour with Ovarian Tumour," and "The Puerperium with Ovarian Tumour." At the end of each part come most important and full tables of recorded cases, which cannot fail to be interesting. Put shortly, the conclusions at which the author arrives are as follows: - In pregnancy, the recognition of an ovarian tumour should be followed as soon as possible by ovariectomy, save in the case of a very densely adherent tumour, the removal of which would almost certainly be followed by the onset of labour. In such a case, the author considers it wise to wait, in the interests of the child, until near full term. In labour, the author similarly considers ovariectomy to be the best treatment, if the patient can be placed without delay in the hands of an experienced operator. If this is not possible, reposition of the tumour may be tried, and, if this fails, the tumour if cystic must be tapped or incised. If it is solid and cannot be changed upwards out of the pelvis it must be removed. In the puerperium, in all cases, Dr. McKerron considers ovariectomy should be performed as early as possible. If the tumour is detected during labour, he considers that its removal may and should be undertaken within a few hours after delivery.

With the treatment recommended in the first two cases we think few will disagree; but we are not quite so satisfied of the necessity for, or the advisability of, operating a few hours after delivery in uncomplicated cases. If a patient has passed through pregnancy with an ovarian tumour, and if the latter has escaped bruising, i.e., has not descended into the pelvis during labour, we confess we do not see why there should be a markedly increased danger during the ten days or fortnight after delivery. Dr. McKerron's own tables substantiate this view. As we read them, out of thirteen patients who were operated upon during the first week after labour, five died; while, out of fourteen patients operated upon on or after the eighth day, only two died. Again, if the high mortality in the first group only shows that the cases were complicated ones, this shows the high degree of success, the second table also shows that the fact of waiting

for a week to a fortnight before operating does not lead to a high mortality. Personally, we consider that, while the occurrence of compression of the cyst or of other injury to it is an absolute indication for operation at the earliest opportunity, in the case of a tumour which has suffered no injury during labour, the time of election for operation is as soon as the patient has recovered from the effects of labour, that is, from the tenth to the twentieth day. An obvious answer, which is to be made to this, is that the presence of a complication may escape diagnosis until it is too late, and that this is avoided by immediate operation. Our point, however, is that the whole question is one of diagnosis. If there is a doubt as to what is happening to the tumour, operate by all means; but if it is obvious that the tumour is undergoing no change and is causing no harm to the patient, it is better to wait.

We are confident that Dr. McKerron’s book will be found of great value to all obstetricians, as it deals, in a clear and interesting manner, with a serious complication of pregnancy which has not before received the attention it ought.

HOLT ON DISEASES OF INFANTS. (a)

The time has passed when the works of American physicians were looked at askance by British readers. At the present time many of them, compare almost equal terms with native authors. This, indeed, as it should be, for science knows no frontiers and merit is the sole criterion of success.

This portly volume, comprising upwards of 1,200 pages, is illustrated by means of photographic blocks and coloured plates, certainly deals exhaustively with the subject of the diseases more or less peculiar to children, or, shall we say, with diseases as they present themselves in the young. It is obvious that diseases met with in adults present special features when they develop in the peculiarly receptive soil afforded by the young organism, while their limited powers of expressing their change and sensations renders diagnosis the more difficult.

The author introduces his subject by remarks on the hygiene and general care of infants and young children. These chapters deserve careful study at the hands of young practitioners, important points being made clear by tables and charts, which serve to emphasise the lesson which the author seeks to convey. It would be well if all intelligent parents could be made to understand the valuable guidance afforded by such charts, for instance, and if they do not it is in great measure due to the fact that their medical advisers do not insist enough.

The chapter on infant feeding has been rewritten in the present edition, and there is a very telling chart giving the value in respect of the various nutritious principles of the principal artificial foods which compete for public favour. Better than any table of chemical formulæ, this chart shows the immense difference between their composition and the normal infant parabulum. The author supplements this demonstration by directions how to utilise these artificial foods without infringing the elementary principles of infant alimentation.

The diseases of the various systems are described seriatim. We note the use of the term “lymph nodules” as an alternative for lymph glands, an innovation which does not commend itself to us. There is a very good coloured plate of Koplik’s spots in measles. Under “Vaccinia,” the author gives a very convincing diagram of the deaths from small-pox before and after the introduction of compulsory vaccination, and in contrast with countries where vaccination is not compulsory. We note, however, that no mention is apparently made of generalised vaccinia, a formidable, if rare form of post-vaccination complications. We have nothing but praise for the work as a whole. The illustrations are numerous and for the most part of excellent quality. The text is lucid and is free from irritating Americanisms. The advice given in respect of treatment is very full and is characterised by sound judgment. It is distinctly a work worthy of commendation, and we know no better treatise on the subject in the English language.

SQUINT. (a)

This is a book of very exceptional value and importance. It possesses the three essential qualities—learning, style, and thought. Mr. Worth does justice to the work in its entirety within the space at our command, but it suffices to say that it is as complete and trustworthy as industry and skill can make it.

There is but one point over which we beg leave to differ from the author, and that is his theory of the squint being an anomaly of the fusion-power. It is the old, old story so admirably summed up by Tennyson: “The law within the law.” There is a well-known fallacy discussed in books on logic—the petitio princi
di—which consists in calling a thing by another name and deluding ourselves into thinking we have defined it. What is the cause of the want of fusion-power? No truly adequate explanation of why the fusion mechanism of the eye is so much weakened that it cannot see the whole ground—has ever yet been given, and, like carcinoma, the actual cause of the disease remains a mystery.

Mr. Claud Worth’s book on the whole may be regarded as the fullest and most authoritative study of the subject to which it has hitherto been presented to the public. It is enriched with carefully drawn diagrams, and we advise all those engaged in ophthalmic work to obtain a copy.

HAIG ON URIC ACID AS A FACTOR IN DISEASE. (b)

This, the sixth edition of Dr. Haig’s book, is a rather bulky volume of more than 500 pages, and as its title implies, it is entirely devoted to a study of the connection which the author believes uric acid to play in the production of functional and organic disease. That this part is an important and comprehensive one may be seen by a glance at the list of uric acid diseases on pages 135 and 136. From beginning to end the book evidences close observation and careful though one-sided reasoning, and is of intense interest. It possesses throughout the merit of originality. Though few will accept one-half of the author’s conclusions, no one can fail to be struck by the freshness of his arguments, and to be pleased to recognise in his tone a healthy and agreeable reaction against what he terms the “mucro mania” of the present day. Latterly too much stress has been laid upon the rôle which microorganisms play in pathology, and the personal element in disease—

(b) “Squint.” By Claud Worth, F.R.C.S. London: Bale, Sons and Danielsson, 1893.

by a special method showed that its uric acid contents was also increased during the attacks. It was then found that the inhibition of acids tended to cut short the attacks and that at the same time they caused a diminution in quantity of the uric acid in the urine and in the blood. The conclusion followed that the cause of the migraine was the presence of excess of uric acid in the blood, and that the acids acted by clearing the blood and causing a precipitation of the acid in the tissues. This view was supported by the fact that the cessation of the headache was often accompanied by twinges of pain in the neighbourhood of the joints, and that the migraine in acid in their turn could be relieved by taking the alcalies which dissolved the precipitated acid and again flooded the blood with the poison, leading to a recurrence of the migraine.

Starting from these facts and working inductively, Dr. Haig has been led to conclude that there are two main groups of diseases associated with the presence of uric acid in the body. The first or "precipitation group due to the irritating presence of uric acid in a fibrous tissue," includes gout, rheumatism, lumbago, and numerous other diseases, the symptoms of which depend upon the particular tissue or organ which has become a uric-acid filter. In many cases, however, the uric acid by itself is not sufficient to cause disease, but being along the vitality of the invaded tissue is supposed to pave the way for the entrance of pathogenic organisms, and since chill, either local or general, is a potent cause of precipitation, we find here an explanation of the relation of exposure to cold and wet to the onset of pneumonia and pleurisy.

The second, or solvent group he calls by the generic term colliam, the essential feature of which is an excess of uric acid in the blood. Invariable concomitants of this condition are high blood pressure, slow cardiac rhythm, slow capillary reflex, diminished aciwdity, and lessened quantity of urine, and the factor which produces these states is supposed to be the separation out of the excess uric acid in a colloidal state in the blood, thereby causing an actual obstruction of the peripheral arterioles. Under this heading more than thirty different diseases are grouped, ranging from nervousness and hysteria to Bright's disease and leucocythemia. The way to avoid both groups of diseases is to avoid the introduction into the body of purin substances in the food, for according to the author uric acid is always formed in the healthy body in the defecation of 1 to 35, and disease results when an excess is introduced from without. Dr. Haig would therefore exclude from our dietaries all animal food except milk and cheese, and would even cut off from pure vegetarians the pulses, tea, coffee, mushrooms, and asparagus, of which he charges terites as deadly poisons. Even oatmeal is condemned. That the theory in its entirety is untenable is readily proved, for Noel Paton and others have shown that Dr. Haig's important premis, the production of uric acid in a constant relation to urea, is incorrect; but despite this the work is interesting, and besides giving some valuable therapeutic hints, affords food for much thought.

Faults of style are abundant, and explanations flow too readily from the author's pen. From among the several tracings which are presented, a considerable number are not in actual accord with his views, but in each case an explanation of the discrepancy, often totally inadequate, is forthcoming. If this style of exposition shall pass the same time they caused a nothing which could not be shown to be the result of excess of uric acid, or, indeed, of any other urinary constituent. If the tracings are only a selection from among the vast number, we are entitled to ask why a more convincing selection was not made. Dr. Haig has quite overlooked the arguments in favour of the flesh diet which may be drawn from a study of comparative anatomy and from a glance at the theory of evolution. In favour of his theory is omitted, and that is that tradition ascribes the commencement of the flesh-eating habits of man and the limitation of his years to three score and ten to the same epoch.

WILLIAMS ON MIDWIFERY. (a)

When a writer of the power and genius of Dr. Whirledge Williams sets his hand to a text-book of obstetrics, the result can be foretold before the book is published, and after publication the reviewer examines it more with the object of determining how far it exceeds his expectation than with any anxiety of criticising it to ascertain whether it is suitable or not for its purpose. Everyone who knew that Dr. Williams' book was in preparation expected that it would be a success, and the volume before us assuredly promises to be. It is written in a clear and admirable manner, it is comprehensive and exact, and last, though not least, it is written in English. It is a pleasure to read an American work written as Dr. Williams has written his, it is a pain to read one in which solemnities of style strive for the mastery with solemnities of grammar.

The book is divided into eight sections—anatomy, physiology and development of the ovum, physiology of pregnancy, pathology of labour, obstetric surgery, pathology of pregnancy, pathology of labour, and pathology of the puerperium. We are sorry Dr. Williams did not add an additional section on diseases of the new-born infant, but perhaps he will do so in a subsequent edition. It is difficult to specify particular parts of the book, which are better than others, where all are so good. Dr. Williams is a pathologist and an anatomist of the first rank, and has done much original work in these departments. Naturally the chapters dealing with those subjects with which his name is especially identified are, perhaps, the most interesting to the specialist. Dr. Williams is well known in connection with work on the bacteriology of the vagina, placental infarctions, and puerperal infections, and the chapters on these subjects are most interesting. One of the few parts of the book which is not quite as full as we could wish is that dealing with many of the other American writers, Dr. Williams is perhaps too summary, and scarcely devotes sufficient attention to this most serious complicatior.

The illustrations are the best of their kind which have been as yet produced, with, perhaps, the exception of Bumm's work on the same subject. They constitute an atlas in themselves, are beautifully drawn, and, like the letterpress, leave little to be desired. Space and time prevent us from reviewing Dr. Williams' book in the manner it deserves. It may truly be stated to be one of the best books of its kind of the present day in the English language, and it may safely be regarded as the one which is the cream of its kind—an ephemeral production, written in order to bring its writer's name into prominence, but which will for many a year remain, like Winckel's classical work, a world-known treatise on the science and art of obstetrics.

FOODS: THEIR COMPOSITION AND ANALYSIS. (5)

The changes introduced into the present edition of this well-known text-book testify to the progress that has been effected, not only in the purely technical details of food analysis, but also in the better and more complete recognition by the legislature of the obligations placed upon it in the matter of protecting the public against fraudulent adulteration. The extension of legislation has had the effect of making much of the work in analysis necessary, and of improving the methods of analysis by the introduction of new methods, and the perfection and development of old methods. The result is that the present edition is much more complete than the previous editions. It is also much more practical, and contains a great deal of new matter. The book is well written, and well printed, and is a very valuable work for all who are interested in the subject of food analysis.
employed, have rendered it necessary to re-write the work in great measure.

The immense experience acquired in the North and Midlands during the recent wholesale arsenical poisoning, has led to a fresh chapter in the analysis of research of arsenic and its congeners, and the volume bears testimony to much careful work in this department. The opening chapters, devoted to the history of action of arsenic and the various measures adopted for its repression, are interesting and instructive. It is plain that though we are fond of calling this the age of adulteration, the practice was rife whenever commerce made its way. The progress of science has proved at least as useful to the ingenious and unscrupulous manufacturer as to the chemist whose duty it is to reveal his delinquencies. Adulteration, however, is now regarded as disreputable, and is punishable at law—in certain of its phases; and this change of front renders it less profitable and less safe to cheat the public in this particular way. We may, indeed, congratulate ourselves on the fact that no country has the legislature taken greater pains to stamp out this form of adulteration. If the efforts of our legislators in this direction have not proved more uniformly successful, the fault lies with the local authorities, so many of whom are indifferent, and, in consequence, to the application of the law. Clause VI. gives a very good résumé of the present law in England relative to the adulteration of food, and may safely be taken as a guide by those entrusted with its administration.

In the book we have described the various forms of apparatus employed in the analysis of food, together with indications for the use of the microscope, spectroscope, and the camera in the detection of foreign elements therein. The remainder of the book is given up to the study of the various articles of food in detail, while Part IX, deals with the examination and analysis of water. It is impossible to speak too highly of the thoroughness with which this gigantic task has been carried out. The mere list of tables constitutes a library of reference, and the labour involved in their compilation must have been what our German friend would call "colossal." The authors rejoice in a lucidity of diction which is as praiseworthy as it is exceptional in highly technical work of this description. It may safely be affirmed that this volume will fully maintain the high reputation gained by its predecessors, for the instruction of those who aspire to the post of medical officer of health or public analyst, for the guidance of those who occupy such posts, and as an authoritative work of reference by those who have occasion to read up specific subjects.

HANDBOOK OF CLIMATOLOGY. (a)

The climatic treatment of disease now occupies such an important place in therapeutic measures, and of recent years so much accurate information has been forthcoming respecting the relative value of different health stations, that it is most desirable that medical men should be thoroughly acquainted with the principles of the science of climatology. And the book before us forms an admirable handbook to the subject.

The preparation of the present volume was undertaken in order to provide a suitable text-book for students. The first edition of Professor Hann's "Handbuch der Klimatologie" was published in 1883 in the "Bibliothek Geographischer Handbücher," edited by Professor Friedrich Ratzel. The second edition, in three volumes, was published in 1897. The first volume of the second German edition is the only one included in the present translation. Mr. Ward is to be congratulated on the excellence of his translation, and such additions and alterations as have been made have been done with judgment and discretion. Numerous references, especially as such are likely to be useful to the English and American students, have been added, and the text brought up to date. It is pleasing to note that every change that has been made has had the full approval of Professor Hann, who has been consulted in regard to all these matters.

Much trouble has been taken to make the work authoritative and absolutely trustworthy. Every reference, the original of which is accessible, has been included, as possible.

The work is very technical, and medical men will find it of greater service for reference rather than continuous reading. Unfortunately, the distinctly medical references are somewhat meagre, but the work deals with the science of climatology rather than its application to the treatment of disease.

The work is a notable one, and is long likely to hold an authoritative position.

CAULEY ON THE FEEDING OF INFANTS. (a)

The second edition of Dr. Cauley's interesting book on the feeding of infants is a useful contribution to this important subject, which it discusses in a scientific manner, with the same time entering fully into practical details. The book commences with a chapter on the physiology of lactation, and the physiological chemistry of infantile dieters; next come the characters of human milk, the contra-indications to nursing, the differences between cows' and buffalo milk; and finally, the practical part of the book, dealing with the different methods by which an infant can be fed. The book is written in a clear and comprehensive style, and is well suited to those for whom it is intended, namely, the newly-qualified medical man or general practitioner. It, however, possesses the somewhat serious fault in a book of this nature that it is not sufficiently definite. In the chapter dealing with the management of artificial feeding, some ten or twelve alternative methods of feeding the infant are recorded, but a sufficiently definite attempt is not made to specify to the busy practitioner who consults the work in haste, which of these different methods the author considers the most suitable. Consequently, the value of the book as a reference in such cases is impaired. This is a fault which is easy of correction and doubtless is the result of Dr. Cauley's dislike to being too dogmatic. Orthodox dogma is, however, always acceptable to the busy practitioner, and Dr. Cauley's dogma is sure to answer to that description. He might, therefore implant a little more of it in his next edition.

POEMS. (b)

It is not often that we are called upon to notice the works of poets in this journal, but the poems of the Rev. W. E. Henley are rich in interest and appeal to the mind, and appeal to the physician with a directness born of intimate knowledge of suffering. Henley's long and courageous fight with physical disabilities is not likely soon to be forgotten. His experiences when a patient under the present venerable Lord Lister in the Old Edinburgh Infirmary provided him with abundant material for his clean-cut delineations of hospital life with its curious blending of science and sympathy, pathology and pathos. The "In Hospital" series occupy the first portion of the present volume. They should be read by all practitioners of medicine. Old Edinburgh men will love to linger about his lines on "The Chief," and will understand the rapture breathing through "Discharged." Henley's verse is full of an all-conquering courage. The bindgewings of chance left him unbowed, unfraid, ready to meet disease and death with a spirit of masterful dignity. We know of no poems of recent date likely to be more helpful to the weary, dejected, overworked practitioner; they are rich in prophylactic and restorative influences; let every

(a) "Handbook of Climatology." By Julius Hann, Professor of Coehnical Physics in the University of Vienna. Part I.; General Climatology with the permission of the German edition by Robert De Courcy Ward. Assistant Professor of Climatology in Harvard University. Pp. 427. New York: The Macmillan Company. 1899. Price 15s. 6d. net.

NEW INSTRUMENTS.

HEMISINE.

Suprarenal gland is in many ways one of the most remarkable of modern therapeutic weapons. It has proved useful in many inflammatory and hemorrhagic conditions of the mucous membranes, such as epididymitis, hay fever, and conjunctivitis. There will doubtless be a large and important field for this powerful agent in gynaecological and dental practice. Already the drug has been prepared in various forms, as might be anticipated in view of the restless activity that characterises modern business methods. One of the most convenient preparations that has yet come to our notice is the "hemisine soloid" of Messrs. Burroughs Wellcome and Co. Each soloid, when dissolved in 5 cc. (0.84 minims) of water produces a solution of "hemisine" in the strength of 1 in 1,000 of normal saline. That degree of solution is fitted for ordinary use, and the general practitioner who carries one of these "hemisine" packets in his pocket case will be so much the more completely equipped against certain of the emergencies of his daily work. So far as the capillary hemorrhages are concerned, suprarenal gland has appeared early to come to stay. We advise our readers to make a trial of the "hemisine soloid" on the earliest opportunity.

The enterprise of the Toilet Novelties Company, Bristol, is now so well recognised as not to need more than passing mention. Their latest departure in the way of toilet boxes containing medicated paper should commend itself to medical men in the treatment of hemorrhoidal and kindred conditions. Another most practical and valuable article is the silky fibre aseptic handkerchiefs specially meant for consumptive patients. These handkerchiefs are made in various sizes, and should command a large popularity in sanatoria devoted to the treatment of tuberculous patients.

New Instruments.

IMPROVED TONGUE DEPRESSOR AND THROAT INSUFFLATOR.

Messes. Burt, By Alex Duke, F.R.C.P.

The instrument illustrated will be found in practice a great improvement on the older patterns, as it is altogether made of metal. No rubber tubing or bellows to become useless in a short time!

This insufflator will be found useful for the application of bicharbonate of soda, &c., in cases of quinsy, or sulphate of magnesia in early stages of diphtheria; any powder preferred can be used, and blown on to tonsils and faucæ (the concave surface of depressor keeping the tongue and a swollen fauces at base, and the division of metal tube on convex surface directing the powder where most required). A small percentage of Eucaine B combined with the powder used will be an advantage, and is to be introduced into opening by shaft-collar, then slid over fenesiba, and the instrument is ready for use.

It has been neatly made for me by Messrs. Arnold and Sons, West Smithfield, and will be found in practice handy, anti-septic, and trustworthy.

DR. J. FLETCHER LITTLE has been chosen Liberal candidate for East Marylebone, London, at the next General Election.

Medical News.

Medical Sickness and Accident Society.
The usual monthly meeting of the Executive Committee of the Medical Sickness, Accident, and Life Assurance Society was held on the 30th ult., at 429, Strand, London, W.C. There were present Dr. de Haviland Hall, chairman; Sir Dyce Duckworth, trustee; Mr. J. Brindley James, Mr. F. S. Edwards, Dr. F. J. Palmer, Dr. A. J. Rice Oxley, Dr. Alfred S. Gubb, Dr. M. Greenwood, Dr. J. W. Hunt, Dr. Walter Smith, Mr. Edw. Bartlett, Dr. W. Knowles-Seyley, Dr. F. J. Allan, and Dr. J. B. Boce. During the year 1903 the Society has shown signs of vigorous growth, the number of new entrants being far in excess of the number obtained in the same period for many years past. At the same time the amount paid away on sickness benefit has been less than last year, notwithstanding the fact that the average age of the members and consequently the expectation of sickness is still growing. A valuation of the business will be made at the end of the current year, and any surplus found will be at the disposal of the members in May next. Prospects and all information of Mr. F. Addiscott, Sec., Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Royal College of Surgeons, Ireland.
The opening meeting of the winter session of the Medical School attached to the Royal College of Surgeons was held in the College, Stephen's Green, last week. There was a large attendance. The President of the College, Sir Lambert H. Ormsby, occupied the chair, and delivered a address, which appears in our present issue. Sir Charles Cameron then read out the list of prizes as follows:—

The late Dr. H. G. Croly.

One of the resolutions passed at the annual meeting of the Royal Academy of Medicine in Ireland was as follows:—"That the President and Fellows of the Royal Academy of Medicine in Ireland desire to express their sense of the loss which hospital work has sustained by the death of Mr. Henry Gray Croly, who has been for so many years an active teacher of surgery and a prominent Fellow in this Academy. The Academy desires to express its condolences with the members of his family."

Presentation to Dr. R. D. Purefoy.

On the 3rd inst., the nursing staff of the Rotunda Hospital presented to the hospital a bronze bust of the late Master, Dr. R. D. Purefoy, in recognition of the many kindnesses they had received from him during his seven years of office. The bust was subscribed to by some three hundred nurses, who also presented Dr. Purefoy an illuminated album of photographs and their addresses and their signatures. Dr. Purefoy, whose term of office is now finished, has undoubtedly done much to promote the welfare of the nurses as well as that of the whole hospital. During his period of office many improvements have been carried out directly by him or at his instigation. Amongst the works directly carried out by him may be specially mentioned the building and complete equipment of a pathological laboratory. We trust that the Board will perpetuate the work he has started by continuing the services of Dr. Neville, the present pathologist. Dr. Purefoy's natural regret at leaving the office must be tempered by the knowledge that he has done the good-will of the entire staff, and that he leaves many permanent memories of his mastership behind.

At the meeting of the Board of the Hospital held on Frthly, November 6th, it was proposed by the Right Hon. T. C. Harrington, M.P., Lord Mayor, seconded by Mr. William Fanagan, T.C., High Sheriff of Dublin, and unanimously resolved:—"That the Board of Governors of the Rotunda Hospital, on the retirement of Dr. Richard Dancer Purefoy from the office of Master of the Hospital, sincerely tender our very best thanks to him for his devoted attention to the patients during his term of office and to the interests of the charity, and devoutly desire to assure him of the appreciation of the distinguished skill which he has shown, and we most warmly congratulate him on the great efficiency of the hospital and on the improvements in the institution which have been effected during his mastership, and which he has so materially assisted to have carried out. We further desire to convey to him our best wishes for his success in his future career."

The Death of the "Lady Doctor."

At the adjourned inquest upon the body of Miss Hickman some important evidence was given by Dr. Thomas Stevenson, analyst. He said that he had received part of the stomach, intestines, and the left kidney. He had also received a six-ounce medicine bottle, a surgical scalple, a hypodermic syringe, a broken case, a sponge, an eight-ounce medicine bottle. The organs were very much decomposed. The evidence of morphia was clear and definite. He estimated the amount at one-sixteenth of a grain. He was of the opinion that a large portion of morphia had been administered. One grain of morphia had been known to be fatal, but two grains were generally regarded as the fatal dose. He could detect no evidence of poison in the six-ounce medicine bottle. There was no blood on the scalpel, which was rusty and old. The hypodermic syringe was an ordinary one and inaccurate, and had been rinsed after being used for a solution of morphia sulphate, of which about one-fiftieth of a grain was left. Three morphia tabloids could be dissolved in the syringe full of water. Four tabloids of a quarter of a grain each would be about the minimum fatal dose.

The London Hospital.

On November 2nd the Lord Mayor and Lady Mayoress of London attended to unveil the tablets over the beds in the Royal Ward founded in honour of the 300th of the King and Queen in July. To the speech of the Hon. Sydney Holland, Chairman of the Hospital, his Lordship said that no more lasting memorial could be made to the memory of man or woman than was afforded by an order recorded in the ledger. The credit for the success of the appeal which had been made to the public was due to the King and Queen.
NOTICES TO CORRESPONDENTS.

W.C.I.—4 p.m. Mr. E. Clarke—Clinique. (Eyes).—5.15 p.m. Mr. E. P. Paxton—Tuberculous Disease of the Knee-Joint.

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.)—2.30 p.m. Clinical Demonstration. Dr. Morgan Docherty.

HOSPITAL FOR DISEASES OF THE THROAT (Golden Square, W.)—4.30 p.m. Dr. Lack—Diseases of the Larynx.

MEDICAL COLLEGE OF ENGLAND (Lincoln's Inn, W.C.)—6 p.m. Hunterian Lectures—Prof. A. M. Paterson.

THURSDAY, NOVEMBER 3rd.

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.)—2.30 p.m. Clinical Demonstration. Dr. Eddowes.

Appointments.

CUMBERLEY, MARY, MAGNIFICENT A.DV., L.R.C.P., M.C., Surgeon to the Court "One and All," Ancient Order of Foresters, Truro.

FARROW, W. T., M.R.C.S., L.R.C.P., Certifying Surgeon under the Factory Act for the City of Silk. (see add.)

HAMILTON ARTHUR, F. M. Bt., M. R.C.S. L., H.R.C., House Surgeon to the West London Hospital.

HANCOCK, A. M. B., B.S., D.R., Second Assistant Medical Officer to the City Asylum, Gosforth, Newcastle-on-Tyne.

Vacancies.

Brighton, Hove, and Sussex Throat and Ear Hospital, Church Street, Queen's Road, Brighton.—Non-Resident House Surgeon. Salary £75 per annum. Applications to E. W. Fissley, Secretary.

Brighton.—Cases of Ophthalmia neonatorum and Cradle Croup. See also Fissley, Secretary.

Dublin.—Children's Hospital—House Surgeon. Salary 50 guineas per annum, with apartments, fire, light, and attendance. Applications to H. C. mooney, Hon. Sec., Medical Board. (see add.)

Grimsby and District Hospital—Resident House Surgeon. Salary £140 per annum, with board and residence, with washing. Application to J. F. Writhlington, Hon. Secretary, St. Mary's Chambers, Great George St., Grimsby.

Manchester Royal Eye Hospital.—Junior House Surgeon. Salary £250 per annum, with residence, board, and washing. Applications to J. P. W. Biddle, Chairman of the Governors, Manchester Royal Eye Hospital.

Mount Vernon Hospital for Consumption and Diseases of the Chest.—Assistant Physician. Applications to William J. Morton, Secretary, 7 Flax Street, W. Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £200 per annum. Applications to the Honorary Secretary, Joseph Carr, 41, Mosley Street, Newcastle-on-Tyne.

St. Mark's Hospital for Skin and other Diseases of the Rectum, City Road, E.C.—House Surgeon. Salary £200 per annum, with board, lodging, and washing. Applications to E. W. Fissley, Secretary.

Sheffield Royal Infirmary.—Matron. Salary £100 per annum, with board, washing. Applications to the Secretary.

Siths.

DYER.—On Nov. 5th, at 25 Aldersgate Street, E.C., the wife of M. D. Dyer, of 25, Euton Street, E.C., aged 58 years.

STEPHENS.—On Nov. 7th, at Elderslie, Huyke, Cheshire, the wife of J. W. Stephens, M.D. CANTAB, of a son.

Marriage.

AYRSHIRE.—On Nov. 5th, at St. James's Church, Piccadilly, John Parkinson Atkinson, B.A., M.R.C.S., L.R.C.P., eldest son of J. P. Atkinson, M.D., of Haffren Walden, to Dorothea, youngest daughter of Charles Francis Hicks, of West Linsdeith, Silverdale, Lancs.

COW—WALKER.—On Nov. 5th, in the Lady Chapel of Clisochester Cathedral, Nigel Victor Coulson, B.S., of Lilac Avenue, Major M. Combe, B.A., to Margaret Hornby, daughter of the late Col. Hornby, Liverpool, and Mrs. Walker and Mrs. M. Combe.

LLOYD—CASEY.—On Nov. 2nd, at the Cathedral, Bombay, India, Captain W. K., of the Bombay Lancers, to Miss Florence E. Lloyd, of Milton-under-Wychwood, Oxon, to Mary Alice, only daughter of Surgeon-General Balbirand, I.M.S., retired, of Clevedon, Somersetshire.

MACBRAYNE—BARRACLOUGH.—On Nov. 4th, at All Saints' Church, West Dulwich, Robert Craig, Surgeon, R.N., to Mary Rose, daughter of Dr. and Mrs. Barracloough, late of Herne Hill.

Deaths.

LAWTON.—On Oct. 31st, at Fook, Dorset, Herbert Alfred Lawton, M.D., L.R.C.P., M.R.C.S., aged 31 years.

OXBOW.—On Nov. 1st, at Hindlip, Worthington, Fray Ormrod, L.R.C.P., M.R.C.S., aged 80 years.

ON THE
DIFFERENTIAL DIAGNOSIS
OF GENERAL
PARALYSIS, ALCOHOLIC
INSANITY AND SENILE
DEMENTIA.

By E. G. YOUNGER, M.D.,Brux., M.R.C.P.Lond.,
Senior Physician, Finchbury Dispensary; late Assistant Medical Officer,
Hanwell Asylum; and formerly Assistant Medical Officer, Metropolitan Asylum, Cateham.

The forms of mental aberration that come under the notice of the general practitioner are manifold and various. They are of importance to him from a professional point of view inasmuch as his reputation may be closely involved in the manner in which they are handled. Of their varying types, as they come under the attention of the alienist physician, it would be easy to write a large treatise. The present intention, however, is merely to sketch in brief outline a few points of practical interest likely to afford useful hints to those engaged in the varied and oftentimes exacting field of general practice.

At first glance it would seem that there should be small difficulty in distinguishing between the above three forms of mental disorder, but a little thought will remind us that they each have not only several symptoms in common, but also some causes as well: and here it may be mentioned that in the diagnosis of mental disease a knowledge of the cause or causes is often nearly as important as a proper recognition of the symptoms. I have seen a good many cases of general paralysis, alcoholic insanity and senile dementia where it was impossible, after even more than one interview with the patient, to distinguish one from the other. I have seen a few where weeks and even months have elapsed before a correct conclusion could be arrived at; and a very few where the question whether the case was one of slow general paralysis or of premature senile dementia with marked muscular tremors has only been decided on the post-mortem table.

General Paralysis.—This disease is commonest between the ages of thirty and forty-five, and is rare after fifty, though cases have been reported as late as sixty. It is quite four times more frequent in men than in women. The principal causes are generally admitted to be sexual excess, long hours of employment with insufficient sleep, alcoholic excess, syphilis. Other causes, such as plumbism and excessive meat diet, have been spoken of. General paralysis is the only form of insanity in which heredity as a predisposing cause can be excluded.

The mental symptoms comprise loss of memory, hallucinations and optimistic excitement, with grand delusions which vary almost from minute to minute. The patient is a duke, a king, an emperor; his house is a marble palace, and the pebbles in his garden priceless gems; he is going to build a railway across the Atlantic and run golden locomotives on it, and so forth. He is likely to commit some foolish theft under the impression that the article is his own, or to expose himself indecently or be guilty of a criminal assault. The physical symptoms include tremors, especially of the tongue and of the facial muscles, and the pupils are always fibrillary in character. Difficulty in articulation and alteration in gait are common, both being due rather to inco-ordination than to actual paresis. The pupils may be unequal in size, or contracted, or pulled out of line, or both. In due course epileptiform seizures, known as congestive attacks, set in. In these the convulsions are not so severe as are those of true epilepsy, and the patient rarely bites his tongue; but each seizure leaves him more paralysed than it found him. There is usually diminution of cutaneous sensibility, and the knee-jerks are abolished or impaired. During the earlier stages remissions may take place, and are sometimes of quite long duration but these are always followed by relapse, and the tendency of the disease is towards increasing paralysis and death.

Alcoholic Insanity.—In speaking of this I do not refer to delirium tremens, but to the less transient mental alteration caused by long addiction to alcohol, where the patient before actual insanity has become apparent has already begun to manifest some of the psychical symptoms of chronic alcoholism, such as diminished will-power, untruthfulness, and cowardice. It is rather commoner in men than in women. In all cases of alcoholic insanity heredity must never be forgotten as a probable predisposing cause, the alcoholic excess being the exciting one. The hereditary factor is too apt to be overlooked, or to be over shadowed by the alcoholic one. In most cases of alcoholic madness, if careful search be made, a family history of insanity, epilepsy, alcoholism, or other neurosis can be traced, and here this form of mental disease differs widely, from general paralysis. I believe that the drunkard with no hereditary neurotic history (if there be any such, which I am sometimes inclined to doubt) runs a far greater chance of ruining his liver and kidneys by his excesses than he does of becoming insane.

The type of alcoholic insanity I have now in my mind is the maniacal one with exalted delusions of wealth and position. The memory may or may not be affected. The mental symptoms are accompanied by muscular tremors and halting alterations in speech. The tremors are often fine in nature, closely resembling those of general paralysis. The pupils are often unequal in size, but never irregular in outline, as in the paretic complaint. The knee-jerks may be abolished in one or both legs, and the gait impaired, but more from true paresis than from muscular inco-ordination. Moreover, cutaneous sensibility remains unaltered. Epilepsy is often an accompaniment of alcoholic insanity, thus importing another element of doubt in forming a differential diagnosis. On the other hand, hallucinations of hearing and touch, delusions about conspiracies and of poisoned food, all rare in general paralysis, are common in alcoholic insanity, and the dissatisfied and suspicious bearing of the alcoholic is in marked contrast to the restless condition of the general paralytic. Should doubt as to the
nature of the case still exist, it may be necessary to
withhold any attempt at diagnosis until the results of
treatment, with the suppression of all alcohol, have been
watched, when the marked improvement in the alco-
holic patient's symptoms will generally clear up all un-
certainty. It must not be forgotten, however, that
treatment, even in intractable cases of senile
and destructive attacks. When the attacks of alcoholic insanity follow
conclusively another it is sometimes difficult to dis-
tinguish the intervals between them from the remis-
sion to the probability of the case being in general paralysis.

**Senile Dementia.** — This is rare before the age of sixty
to sixty-five, but it sometimes belies its name by appear-
ning quite early in the fifth decade of life, thus remind-
-ing us of the adage that we are all senile, even as our
arteries. It is common to both sexes, and is a
primary disease, having for its origin the degenerative
lesions of old or worn-out tissues. Alcoholic inter-
permeation in earlier life is one very common cause.
Heredity, also, is a usual factor, the tendency to senile
dementia running in some families. A few of these
patients have grand and expansive ideas, associated
with optimistic restlessness, in addition to the typical
loneliness in which is always present, thus
resembling general paralysis, but in senile dementia
the maniacal attacks are often alternated with melan-
cholic turns, which is not usual in the former disease.
Two peculiar traits, however, are similar to the typical
tremors of advanced age rather than the fibrillary ones.
I have already spoken of as being characteristic
of general paralysis, and, in a lesser degree, of alcoholic
insanity. The attacks are usually to the facted, thus
contrasting with their condition in the two above-
mentioned states. Epilepsy may be present, a
complication adding to the difficulty of arriving at a
correct diagnosis, but *arcus senilis*, if apparent, will
point the way. Later on, especially if the patient
has been given to alcoholic excesses, the ataraxia and
indifference, and, in some cases, the slowness of
speech, are remarkable, and indicate this, and I, as well as the asylum physicians,
were inclined to suspect senile mania with megalomania.
The diagnosis remained in doubt for more than a year,
when he was seized with undoubted congestive attacks,
after which his paralytic symptoms became more
marked, and there was then no doubt of the existence of
general paralysis.

**Case 1.** — In February, 1900, I was asked to visit and
report upon the mental condition of a young lady, at.
27, who had recently been admitted to a private
asylum. No family history could be obtained, but the
personal history, so far as I could get it from the
friends, who were very untruthful, was that the patient
died of a fever for a few years in concurrence with a gentleman
man, who had died a month or two before I saw her,
and had left her in very comfortable circumstances,
but that after his death she had taken to drink; soon
becoming insensible. Later on, when I was learned from another
that she had been a hard drinker for many years, and
that there was a doubt whether she had not led a life of
prostitution prior to her falling in with the gentleman
above mentioned. When I first saw her she was
restless, mischievous, destructive and utterly
incoherent. She talked incessantly, and there was some
clipping of words as well as tremor of the facial muscles.
No pupillary abnormalities could be perceived, but I thought of the possibility of general paralysis, especially
as she was said to have had a slight epileptic fit. She
was in poor physical health. I saw her again six weeks
afterwards, when she was more composed, but still
incoherent and incapable of sustained conversation.
She talked about her personal appearance, and leered
amorously at the solicitor who accompanied me and
myself. There had been no more fits. In the
following May, when I visited her, she had become
very debilitated from severe episodes of
seizure; she was again utterly incoherent, abused
herself openly and shamelessly, yelling that she was
getting younger and lovelier every day. I saw her
again in October, when she was quieter and more
imbecile, but still with an exaggerated idea of her
loveliness. She had no recollection of ever having seen
me before. She had had, I was told, occasional slight
epileptic fits. I paid visits to the patient for a period
of over two years, sometimes finding her quiet, im-
becile, and forgetful, and at others maniacal, noisy, restless
and disgusting, practising self-abuse, and smearing
herself and her bed with excrement. For a
long time both the medical staff of the asylum and I
myself were undecided as to whether this was a case of
general paralysis or of alcoholic insanity. By degrees
she began to end in incoherent and chronic
Dementia, especially where the patient has had several
attacks. Where the attacks of alcoholic insanity follow
conclusively another it is sometimes difficult to dis-
tinguish the intervals between them from the remis-
sion to the probability of the case being in general paralysis.

**Senile Dementia.** — This is rare before the age of sixty
to sixty-five, but it sometimes belies its name by appear-
ning quite early in the fifth decade of life, thus remind-
-ing us of the adage that we are all senile, even as our
arteries. It is common to both sexes, and is a
primary disease, having for its origin the degenerative
lesions of old or worn-out tissues. Alcoholic inter-
permeation in earlier life is one very common cause.
Heredity, also, is a usual factor, the tendency to senile
dementia running in some families. A few of these
patients have grand and expansive ideas, associated
with optimistic restlessness, in addition to the typical
loneliness in which is always present, thus
resembling general paralysis, but in senile dementia
the maniacal attacks are often alternated with melan-
cholic turns, which is not usual in the former disease.
Two peculiar traits, however, are similar to the typical
tremors of advanced age rather than the fibrillary ones.
I have already spoken of as being characteristic
of general paralysis, and, in a lesser degree, of alcoholic
insanity. The attacks are usually to the facted, thus
contrasting with their condition in the two above-
mentioned states. Epilepsy may be 'present, a
complication adding to the difficulty of arriving at a
correct diagnosis, but *arcus senilis*, if apparent, will
point the way. Later on, especially if the patient
has been given to alcoholic excesses, the ataraxia and
indifference, and, in some cases, the slowness of
speech, are remarkable, and indicate this, and I, as well as the asylum physicians,
were inclined to suspect senile mania with megalomania.
The diagnosis remained in doubt for more than a year,
when he was seized with undoubted congestive attacks,
after which his paralytic symptoms became more
marked, and there was then no doubt of the existence of
general paralysis.

**Case 2.** — Some months past a gentleman, aged 60, already interned in an asylum, possessed of large property, but who had for some months past caused much anxiety to his friends by his altered demeanour and habits of life. There was no heredity of insanity, and no history of sexual excess, alcoholism, or fits. From being a man of most exemplary ways and placid disposition, he had become restless in habits and lewd in talk; he had squandered his money on a glamorous youth who would drink with him; had bought a yacht for which he had no use, and which 'the re-sold at a great loss; had walked into the street in his night-gear and was alto-
ternately a scold and a maniac.

When I saw him he boasted of his superiority of mind and his success in all the financial ventures he under-
took. He was hilarious and elated, greeted me as an
old friend, tly sug he had been, and invited me to luncheon. He rambled from one subject to another in a most irrational way, and his memory was greatly impaired. He had a delusion that he had come to the asylum of his own free will with a view of
being treated partly for insanity, partly for epilepsy. His
lips were tremulous, his speech was slurring, and gait shuffling. There were
no pupillary abnormalities, but he had marked
*arcus senilis*. In this case, although many of the symptoms pointed to general paralysis, the age seemed to conflict with
and indicate this, and I, as well as the asylum physicians,
were inclined to suspect senile mania with megalomania.
The diagnosis remained in doubt for more than a year,
when he was seized with undoubted congestive attacks,
after which his paralytic symptoms became more
marked, and there was then no doubt of the existence of
general paralysis.

**HEADACHES.**

By N. BISHOP HARMAN, M.A., M.B. Cantab.,
F.R.C.S. Eng.,
Examiner in Anatomy at University of Cambridge, Ophthalmic Surgeon Belgrave Hospital for Children, Chief Clinical Assistant Ophthalmic Surgeons' Eye Hospital, Queen's University, Medical School, and Demonstrator in Pathology at the Middlesex Hospital Medical School.

Despite the emphasis laid by writers of a romantic
turn upon aches of the heart, it is doubtful if there are
any aches so distressing and incapacitating to the normal
man as a headache. Reasons for the serious influence of
such an ache on the efficiency of his economy are not far to seek. To every test applied to his body with a
view to the indication of the dominant influence in
that organism the response comes prompt and
decisive—the head rules when the body is healthy. An
appeal to comparative anatomy shows that the head
has become progressively the dominant partner in the
organism as that organism has risen in the scale of
the phylum. Amongst the races of men, physical anthro-
pology gives no uncertain testimony to the general
ability of the head to dominate the body—either generally, or in its actual
No wonder, then, the ache of the head is the
most incapacitating of aches!

One would almost think from the importance of the
ancient artist's and poet's attention to the organ of beauty, and the many virtues and vices they sought therein,
to the exclusion of the mysterious brain-pulp, that headaches were little known to them. We might take umbrage to ourselves that only with us has the head triumphed, even though it be at the cost of an atmosphere; but not the partiality for a friend's little friend, who, stricken in the harvest field, cries to his father, "My head! my head!"

I purpose to remind you of a few of the causes of such aches, some which have recently come under my own observation, but others of the past.

The "congestive" headache we have always with us: the sense of fulness of the forepart of the brain, as "a ball rolling loose within the head," associated with early morning, a heavy, unrefreshing sleep, a foul tongue, and obtuse and confused bowels. It is but a step to the pronounced "head" of the debauchee, his system choked with the relics of a night's carouse; the symptoms are the same, the degree varies.

Home folks are so saturated with a pseudo-medical parlance that the tale of their woes is too biased to be of much value. During the war I was on shipboard in charge of Boer prisoners; their economy was greatly disturbed by an unaccustomed indolence and poverty; and, as usual, the sensations and sympotms they described were as graphically as "drunk in the head." Did the phrase arise from some memory of the morning succeeding a particularly joyous "nachtmaal"?

It would seem that the "headache of fever should be severed widely from these grosser aches; but again the symptoms are similar, it is but the degree that varies. I might, perhaps, hardly dare write from this judgment of patients' symptoms, or from general consideration, had I not experienced a bout of enigmatic fever, and retained recollections of the similarity of the sensations of the earlier days of the fever and those of a common "congestive" headache. But I cannot do better than give the words of a medical friend, who had as bad an attack of this fever with hyperpyrexia as a man may have and live. He writes: "After a holiday trip on leave, from which I returned as fit as ever I have been, I recommenced work at Pretoria. One day I felt giddy and stupid, so took a walk to 'walk it off'; the sun felt hot. The second day--worse. The third--did not, went to bed. Fourth day--awoke early morning with an appalling heavy pain in my head, like a weight that seemed to press into the brain with an intensity that drove me mad. The area of pain was sharply limited by the bounds of the frontal bones, its greatest intensity at a point dividing the muscles. Some relief was given by the ice bag; temporary restfulness followed the use of phenacetin. From now on and onwards sleep was impossible; a short doze was quickly broken by the pain. So prolonged was the pain when animation came. The temperature for three weeks ranged from 103° to 104° F."

"Full fourteen days later I again seemed to know where I was. I felt cold"--the heart was dilating and failing; the patient was put on the "D.I." (dangerously ill) list"--but was quite happy, had no pain, and did not feel ill at all, only too weak to help myself."

In each of these conditions, then--"congestion," disease--the heavy pain is the same; it is intense, as of a mass pressing and sinking into the brain. So also, the causes are similar. The "congestive" is coincident with an ill-cleaned gut--ill-cleaned, not necessarily constipated. Many folk justly deny the suggestion, but the refinement of their diet provides little or no waste whereon to scour the gut; products of intestinal putrefaction poison the system. The head, the dominant partner, suffers above all.

In the debauchee, the body, sodden with a foreign fluid, the headache the result of the relics of a night's carousal, week of the tired stomach, fails not to suffer in the head, which seems "bursting," poisoned by the abnormal food. In the fever, toxins known and unknown do the same work with a greater intensity. In each condition, to the head or sedatives will allay the pain; but elimination of the poison--a purge in the first, a vomit in the second, the loss of power in the infective organisms and their toxins or their excretion in the third--and the poisoning ceases; the head is clear. The life of my friend on the twenty-third day of his fever was despaired of, but he "was quite happy, had no pain, but still not feel ill." His dominant partner was relieved of the poison.

There are many causes other than these which produce "inside" headaches--the grievous pain of meningitis, cerebral tumour, heat-stroke, and the lesser pain of fits and migraine--but that I leave, save the last, which will be dealt with later.

If, as I have suggested, we make a group of "inside" headaches, we may well follow with another group of "outside" headaches. These are in the main the sign of local stresses rather than of a systemic disturbance.

What numbers of folks appear at ophthalmic hospitals who have drifted thither--when long and careful treatment of general conditions has failed to bring relief of persistent headache--if haply some eye trouble may be the source of the discomfort. There are not many who apply in vain. Their headache, if carefully investigated into, will almost always be referred to some superficialities--brow, occiput, around the orbit, and occasionally behind the eyes. In the greater number of cases an error of refraction due to a too short eyeball will be found.

The normal eye being adjusted by the shape of the globe and the arrangements of its refractive media for clear vision at infinity, or for all practical purposes six metres and beyond, it is at rest for most visual work; muscular activity only comes into play in the production of clear vision of near objects, when both intra-ocular muscles of accommodation and extra-ocular muscles of convergence work harmoniously and unconsciously to produce the desired effect. The short eye can, however, never be at rest if good vision be desired for either far or near objects. The intra-ocular muscles adjust the lenses for distant objects, and this adjustment must be produced without the concomitant action of convergence--indeed it is the order of things. Hence the strain and fatigue attending all vision, much for distant and more for near, so long as binocular vision is maintained. In severe cases, particularly where the desire for binocular vision--the "fusion faculty"--is not keen, the strain becomes too great; the convergence natural to the accommodative act is allowed--one eye fixes, the other accommodates--the vision is superfluous. Now the pain of the headache, vanishes. That the pain has its source in the effort required for binocular vision under an abnormal accommodative act is, I believe, true, both by reason of its disappearance with the onset of sleep, and also because the same type of symptoms are found when, with no abnormality in the shape of the eye, there is an irregularity in the balance of the extra-ocular muscles, a deficiency in the power of convergence, or, in other words, much power is required to produce a naturally simple and unconscious act.

In some few such cases the pain is definitely localised within the orbit, and we naturally think of the extra-ocular muscles. In the majority, however, it is otherwise; brow or occiput is the site. Some have sought a solution in fatigue of the muscles of these regions, which are undoubtedly called into action by pain, strain and tortonions, the act of vision--contortions which frequently result in the handicap and twitches of nervous children. Doubtless this is the true solution in some cases, particularly so in occipital headache. But this can hardly be the whole truth, for in no condition are the facial muscles more adiuvant to vision than in myopia, in tricks of facial movement, which have given the name to the disease; and rarely is it the cause of much malady. Many, not knowing they see little or nothing of the beauties of the world, go their whole life boasting they can read the smallest print, even in their dotage, without the aid of glasses; of headache there is never complaint, yet their brows are always drawn by the constant action of a well-developed musculature. Muscular strain may be shown either by fatigue
or simple over-action, or by neuroses or abnormal action. It is to this latter cause these eye headaches and those episodes of accommodation and convergence the sensory nerves to both intra- and extra-ocular muscles are in a constant state of irritation, and the irritation is referred to those greater branches of the same trunk spread above, the brow, the eye, the nose, the temple, and the occiput, and not infrequently definitely referable to the lines of distribution of these cutaneous nerves, is to be found in acute disturbance of the tension of the eye, in glaucoma. Here the irritation of the smaller sensory branches distributed within the globe produces an intense degree of irritation in all the branches of the trunk. So marked may be the referred pain, the attention of the patient is directed to his neuralgia of the eye, or perhaps to the neglect and irreparable damage of the eye.

Such pain may be induced by direct irritation to the ciliary body, as in a case I had recently where an over-mature cataract acted as a foreign body within the globe, produced an exudative cyclicity, and a rise of tension with great distress. Rest and sleep followed the removal of the lens.

I will last deal with is that of migraine. I well remember my first acquaintance with this curious disturbance. One of several small boys seated in a class, I was striving to imbibe the store of knowledge possessed by a zealot master. It was in midst of receiving a stern reproof for some neglected work I noticed to my alarm that the half of the threatening face vanished from view, to be speedily replaced by bright dancing figures. My first fancy was that within some terror proceeding from my tyrannt, but succeeding sensations made it clear that it was my own head that acted strangely and not his, a conclusion, did need support, speedily assured by my master's attention and kindness. I noticed an improvement of convalescence from fever in South Africa I had and noted the phenomena attending several attacks. The well-known bright scintillating patterns, in my experience very like the "zig-zag" and "dog-tooth" mouldings of Norman architecture, were disposed in perfect horse-shoe form, and commencing centrally spread outwards and disappeared. In one such attack I found I could vary the direction of the lines of scintillation by a change in position of the head on the bed. On another occasion, before the cessation of one set of left-sided hemispheric phenomena another and right-sided set appeared, so that the two attacks were for a time continuous, and the field of visual gaze greatly diminished. The headache—a dull pain as of a wound within the brain, mostly posterior parietal in situation—followed, and in proportion to its intensity a sense of nausea was added. In not a few instances a stiff or volatile would abort an attack; in others rest in bed and sleep alone brought complete relief.

Some are of opinion that the condition is purely cerebral—a nerve storm; possibly this is so. I cannot help thinking, however, a deficiency of vascular tone is at the root of the matter. The attacks are more common among women than men; women suffer frequently at the menstrual periods and other times of vascular unrest. It is possible sometimes to produce experimentally a miniature representation of the attack. When, after a period of heavy work, a full meal be taken and the body bent low as in removing one's shoes, the sudden assumption of the erect position will cause a momentary blindness, giddiness, and head pain distinctly akin to migraine. In this experiment the sudden change of position, when the circulation is already greatly fatigued, and diversion of much blood to the abdominal viscera produce a temporary cerebral anemia. This view seems to be supported by the observation I made of the variation of the visual aura during an attack, by change of position of the head. There is the necessary apparatus for vasomotor action in the cerebral circulation, though all attempts to prove its action have failed. May not the local cerebral disturbance of migraine be some indication of the possibility of an active arterial variation?

The reason for the association of this neuro-vascular aura with the visual centres is not so easy of solution. Certainly it is that in many cases the vision is defective, a general weakness intensifies the local defect and strain, and the storm starts from the connections of the point of greatest irritability. The removal of this link is often effective in preventing the attacks, even as the constriction of a limb above an aura epileptica in suppressing the graver fit.

A case recently coming under my care aptly illustrates these points. A lady, aged 20, of peculiar disposition, and prone to lapses of self-control, suffered from "fits." There was a history of these fits occurring over several years. Their frequency had greatly increased of late; often the intervals were a week or more. They were particularly likely to occur at menstrual periods. The phenomena of the attacks were described by a very intelligent friend; they tallied well with the picture of epilepsy, save at one point—consciousness was not lost. The patient's own account was rough, but to the point: "A light darted out of the left eye, then all went dark, and the head was very bad." She recognised that she did not become unconscious. There was also an attack of severe headache at another time, and worse in recent months. The story inclined me to discredit the idea of le grand mal in favour of le petit mal. An examination of the eyes elicited the presence of a small degree of myopia and anisocoria. It was noticed that the left eye was more defective than the right. These errors were corrected by glasses, and there have been no more "fits," and the headaches have ceased during the latter half of the month.

The well-known bright scintillating patterns, in my experience very like the "zig-zag" and "dog-tooth" mouldings of Norman architecture, were disposed in perfect horse-shoe form, and commencing centrally spread outwards and disappeared. In one such attack I found I could vary the direction of the lines of scintillation by a change in position of the head on the bed. On another occasion, before the cessation of one set of left-sided hemispheric phenomena another and right-sided set appeared, so that the two attacks were for a time continuous, and the field of visual gaze greatly diminished. The headache—a dull pain as of a wound within the brain, mostly posterior parietal in situation—followed, and in proportion to its intensity a sense of nausea was added. In not a few instances a stiff or volatile would abort an attack; in others rest in bed and sleep alone brought complete relief.

Some are of opinion that the condition is purely cerebral—a nerve storm; possibly this is so. I cannot help thinking, however, a deficiency of vascular tone is at the root of the matter. The attacks are more common among women than men; women suffer frequently at the menstrual periods and other times of vascular unrest. It is possible sometimes to produce experimentally a miniature representation of the attack. When, after a period of heavy work, a full meal be taken and the body bent low as in removing one's shoes, the sudden assumption of the erect position will cause a momentary blindness, giddiness, and head pain distinctly akin to migraine. In this experiment the sudden change of position, when the circulation is already greatly fatigued, and diversion of much blood to the abdominal viscera produce a temporary cerebral anemia. This view seems to be supported by the observation I made of the variation of the visual aura during an attack, by change of position of the head. There is the necessary apparatus for vasomotor action in the cerebral circulation, though all attempts to prove its action have failed. May not the local cerebral disturbance of migraine be some indication of the possibility of an active arterial variation?

The PREVENTION OF INSANITY.

By F. W. EDRIDGE-GREEN, M.D., F.R.C.S.

There is little doubt that insanity is on the increase. It may be well, therefore, to consider the means which may be taken to prevent its occurrence. Though insanity cannot be regarded as a preventible disease in the sense that typhoid and small-pox are preventible, as it depends upon causes of an entirely different nature, we can, as in typhoid, prevent the disease by removing the cause. The means to be taken to prevent insanity may be summed up in a few words, which would apply equally well to any other disease—namely, the removal of the predisposing and exciting causes. I think that there can be no doubt that if the exciting causes be sufficiently powerful any person may become insane, though the power of the factor necessarily varies considerably according to the person. There is no doubt that the cause which would make a person with a highly unstable nervous system insane might have no effect whatever on a more healthy individual. The opinion has been expressed that only certain persons can become insane, but just as a person with healthy digestive organs may suffer from the continued abuse of those organs, so may the healthy nervous system give way under con-
ditions of exceptional strain, or through the direct influence of syphilis and various toxemic conditions. On the other hand, a person who is strongly predisposed to insanity by hereditary influence may escape an attack through the absence of an exciting cause. The removal of the exciting causes of insanity may in many cases appear at first sight an impossibility, as, for instance, in puerperal insanity with strong hereditary influence. I am not considering the question of marriage in these cases, but am supposing that the patient when first seen has married and become pregnant. In a case of this kind there are many influences at work to produce insanity, some of which can be removed. The fact that a mother has become insane at the time of childbirth is a source of continued worry to her daughters, who are afraid that they may suffer in a similar manner. This might be used to say that such cases might seem the most difficult in which to prevent insanity, a very great deal may be done to obviate this disaster, and it will comfort the patient considerably to know of this and that precautions will be taken. I am certain that a great many cases of puerperal insanity are due to toxemia arising from an extended condition of the patient and the symptoms rapidly disappear when these are rendered aseptic. The unstable brain when once damaged by toxemia may never again regain its normal functions. It is, therefore, of the greatest importance that this and other preventable causes should not be allowed to act. In the case of a woman, there is the temptation to puerperal insanity. The most important precautions should be taken with regard to asepsis and the prevention of any undue expenditure of energy. Great attention should be paid to sleep. Loss of sleep for one or two nights may be sufficient to start an attack of puerperal insanity. Any friends who irritate the patient should be prevented from visiting her, and great attention should be paid to her and to the care of her. All excitement should as far as possible be prevented, particularly during the evening, as it is likely to cause lack of sleep. In cases in which there is restlessness and want of sleep, I find bromide of sodium the most useful drug as a sedative. The patient should be watched closely and the ward should be kept under control.

In all cases in which there is a strong hereditary predisposition to insanity the stress and worry of a town life and excesses of all kinds should be avoided. A man who, under difficult competition in a town, would become insane might remain healthy with an easy country life. This more particularly applies to those who have in themselves shown evidence of insanity. There are certain occupations which are more likely than others to produce insanity, such as occupations in which there is work without suitable companionship, particularly if the work be unconsidered and of a worrying nature. This more particularly applies when one faculty or set of faculties is used. It is not uncommon for the absence of suitable companionships to tend to introspection and an unhealthy, eccentric state of mind. It is not advisable that a person who has had one attack of insanity should marry, or that there should be marriage between those in whom there is an hereditary tendency on both sides to insanity. This more particularly applies to the marriage of near relations, such as cousins.

It is very important to note the first symptoms of insanity and to remove all defective hygienic conditions. Any bodily complaint should be cured and attention should be paid to malnutrition and want of sleep. Early treatment will often prevent an attack of insanity.

Those cases which fall on the borderland of insanity are especially those in which the presence or absence of an exciting cause will determine whether there will be an attack of insanity or not. I am certain that a great many absolutely distinct conditions are included under the name hysteria, and that in the future different causes will be found for each. There is one variety of hysteria which is closely allied to delusional insanity, and, in fact, very often terminates in it. The patient has a certain fixed idea, as, for instance, that she will be ill for two or three days after an action of the bowels, and therefore prevents them from acting as long as she can. Though she undoubtedly does apparently suffer, her result is due to an hypochondriacal passion and the symptoms rapidly disappear when these are rendered aseptic.

Persons vary very considerably in their influence to suggestion. If a number of men be told after drinking the best obtainable whisky that they have had some of the very worst and they cannot escape without a headache next morning, many will suffer in this way. Some men, even when in high spirits at the time, can be made quite dejected when told how very ill they are looking. In the same way when a celebrity has had a certain complaint a great number of persons imagine that they are suffering in a similar manner. In the case of hysterical persons it is very difficult to overcome the fixed idea. This idea becomes stronger as time goes on, until the renewal of the impression may pass into a delusion held to be true from single impressions, and every time the impression is revived it becomes more vivid. A simple example will explain what I mean. A man may see another man on two or more occasions and not recognise him, though certain associations of ideas might make him remember that he had seen him somewhere else. It is obvious that the impression must be much more vivid if he had recognised his acquaintance on the occasion of each meeting. In that case the first impression would be revived each time. In order to counteract the effect of the dominating idea the attention should be directed into other channels, and if this fail hypnotism may be tried. The great advantage of a hobby to any person is that it prevents him from dwelling on a particular idea, and from becoming introspective. The present system of classical education is responsible for a good deal of insanity. The subjects taught to a boy or a student should be those which will be of most use to him in after life, and they should be made as interesting as possible. A man who has an ability for learning and who suffers much when taught in this way, but another not possessing this ability, but really a far abler man than the other, may suffer considerably. The endeavours to force a faculty to do work for which it is unfitted produces a state of nervous exhaustion which is surprising when the amount of work which can be done through in another direction is noted. In the process of education every faculty should as far as possible be employed, and those who find solitary work distasteful should avoid it.

Space will not permit me to continue in detail
each of the causes of insanity, neither is it necessary, as many of the cases are such that they only affect the brain because it is the weakest part of the individual, and may in another cause disease of an entirely different nature. A perfectly healthy man may become insane by leaving a country life and coming to a town, where he has no friends; neglecting the exercise to which he has been accustomed, and adopting a sedentary, monotonous employment in a badly-ventilated room; indulging in intemperance in drink, excessive smoking, and dissipation of all kinds; omitting to take proper meals or sleep, and spending his spare time in speculation and gambling. I will conclude by drawing attention to the fact that the nervous system is particularly unfitted to bear any strain when in an ill-nourished condition, and may degenerate under these circumstances when no effect would have been produced if the brain had been supplied with a sufficient quantity of healthy blood.

**Clinical Records.**

**CASE OF TUMOUR OF APEX OF ORBIT (PROBABLY SARCOMA).** *(a)*

By **Arthur H. Benson, F.R.C.S.,** and **Langford Symes, M.D.**

C. C., a married woman, aged 48 (S.M.O.H. No. 51; 28-7-02), came under my care in January last, suffering from total blindness of the right eye and some proptosis.

**History.**—She stated that three years previously, when feeding a calf, the animal suddenly raised its head, striking her right eye.

In the right eye the sight began to fail about three months after this blow, and was almost wholly gone in twelve months. Ever since the sight began to fail the right eye has been swollen and pushing out.

The left eye was quite well, she says, till a week ago, when it got red and painful, and the sight in it began to fail. This was caused apparently by an attack of iritis, and there were signs of synchiae posterior already found; vision was only 6/18ths, tension was normal, and there was doubtful haziness of the disc.

In the right eye, the one in which she had received the original injury, sight was absolutely lost.—R.V. = 0.

The tension was normal, the papilla was semi-dilated, and acted to accommodation but not to light, and under atropin diluted evenly. There were no evidences of iritis past or present.

There was total white atrophy of the disc, but otherwise the contents of the globe were normal.

The eyelids were red, thick, and swollen, especially the upper one, and appeared to be bulged out by a soft mass under them. The conjunctiva was thickened and covered by a network of veins, but there was no conjunctivitis, properly so-called, and the lids had grown in proportion to the mass below them, so that they easily closed over the cornea under any undue pressure. Masses of tortuous and varicose veins were specially abundant at the outer side of the conjunctiva. The globe appeared to be displaced downwards half an inch, and outwards a quarter of an inch, and forwards half an inch.

The movements of the globe were very limited in all directions.

On examining the socket nothing of the nature of a definite tumour could be felt, but the mass of tissue under the lids felt rather lumpy, with here and there a slippery nodule like a melon-seed body. The first idea that suggested itself was a vascular tumour of some sort, but pressure did not produce diminution in the size of the orbital contents, or permit the globe to go back at all, nor was any vascular murmur discoverable with the stethoscope.

Fatty tumour was the next most likely, but no definite limits to the tumour could anywhere be felt, and if fatty at all it must be hypertrophy of the orbital fat in general; but neither hypertrophy of the orbital fat nor a varicocele would account for the great immobility of the globe.

There was no vascular murmur, as I have stated, but there was an extraordinarily loud respiratory murmur heard both with inspiration and expiration. It was heard both over both eyes, but very much louder over the right eye.

At this stage of the investigations she suddenly disappeared from hospital and went back to co. Galway.

Six months later she returned with a fresh attack of iritis in the left eye, and was sent to the Royal City of Dublin Hospital. The respiratory breath was as loud as ever. The proptosis and other conditions had hardly changed at all during the time, though the conjunctiva of the right eye was more watery and the varicosity of the vessels was greater, as also was the general fulness of the orbit. Still no definite tumour of any sort could be felt.

I showed the case to all my colleagues at both hospitals, but no definite diagnosis was arrived at, so I made an exploratory incision, removed a large quantity of superfluous orbital fat, and eventually was able to get my little finger deep enough into the orbit to feel a solid mass surrounding the eye-ball, and situated at the back of the globe. In its hollow the globe sat, like a coron in its cup. It was very hard, and was with considerable difficulty shelled off from the walls of the apex of the orbit, into which it fitted accurately.

I have this day (November 6th, 1902) heard of the woman, and her husband says she is better and gone, on well, and that he hoped she would soon be all right. She wears an artificial eye. The very slow growth of the tumour and its very slight apparent malignancy and the most remarkable respiratory bruit are worthy of special note. The specimen I handed to Dr. Symes for examination, and he has kindly made sections of it, which will explain its nature.

**Pathological Report by Langford Symes, M.D.**

The tumour measures 2 in. by 1½ in. It is a firm, solid mass, tolerably hard, and white on section. It is not encapsulated. It was removed in one piece and had apparently no bony attachment. The optic nerve can be traced through it. The eyeball is free, and was lodged in a depression of the surrounding growth.

**Microscopically.** (1) Low power: It consists of a conglomerate mass of separate loculi, of small size and irregular, or oval, or oval, giving the tumour an alveolar appearance. These loculi contain masses of cells, whose nuclei swell well, and are of round or ovoid form. Some of these have invaded the sheath of the optic nerve. (2) High power: The walls of these loculi are seen to be composed of cells of elongated or spindle shape, arranged in a circular fashion around the alveolus.

The chief points about the tumour are:—The three number of these loculi; their small size, the density with which they are packed together, and their walls being composed of elongated cells.

As to the nature of the tumour, it apparently belongs to the sarcoma, but has a peculiar locular or alveolar arrangement.

**Special Articles.**

**BRITISH SANATORIA FOR CONSUMPTION.—XX.**

[By our Special Medical Commissioner.]

**The Chiltern Hills Sanatorium.**

High above the Thames valley, on the Chiltern Hills, in that delightful district of Oxfordshire which lies south of the popular village resort of Nettlebed, five and a half miles from Reading and some four and a half from Henley, King's College sanatorium for the open-air treatment of consumption, is situated.

The sanatorium stands at an altitude of 375 feet, in open country, and close to the beautiful commons of
Peppard and Kingwood. The district is distinguished for its bracing air, and is well suited to the needs of tuberculous cases.

The sanatorium is placed in the midst of a fruit and dairy farm fifty acres in extent. The original house, which has been in great measure reconstructed and extended by the addition of a new wing, is admirably fitted for its present purpose. It has a south-east aspect and stands in a cherry orchard, which adds greatly to the attractiveness of the place.

The soil is light and porous. A considerable amount of sunshine is enjoyed and good shelter from winds has been secured. The sanatorium is excellently designed, spacious, and air-tight, and the air turbulence prevents any retentiveness of the air, which adds much to the attractiveness of the place. The rooms are well arranged, suitably furnished and admirably kept. On every hand there are abundant evidences of sound common sense, scientific precision and a rational recognition of clinical requirements.

The dining-room is light and airy and conveniently placed at one end of the building. The recently-built sleeping bungalows are excellent in their effective simplicity, and while securing comfort for the patient, at the same time allow of the greatest possible exposure to freely circulating fresh air. The day shelters are good based in the house warm in winter by a supply of hot water pipes. Lighting is by acetylene gas, the manufacture of which is very simple, and we were assured that this form of illumination proved quite satisfactory. Water is obtained from a new boring recently sunk at a cost of £278. Earthworks were used, and are efficiently managed. Treatment appears to be conducted in accordance with strict hygienic requirements. Dr. Colebrook lives in the sanatorium, shares the life of the patients, and so exercises the constant superintendence so necessary for effective control and absolutely essential for the maintenance of satisfactory progress.

We inspected the whole of the sanatorium, and particularly of the patients, and found all excellently arranged and efficiently conducted. The majority of the patients are women, but the treatment of tuberculous and delicate children is made a special feature, and, needless to point out, the farm-yard life and garden-existence present ample attractions. This sanatorium is particularly well suited for children. Physical training and development are provided for, and arrangements can be made whereby lessons or study when so chosen may be given.

We consider this a most important point, for it cannot be denied that life as lived in most sanatoria is apt to become altogether self-centred and utterly selfish, and some of these establishments often permit the development of traits of character detrimental to the highest good of the patient and objectionable to attendants and friends.

The regular terms are from three to four guineas weekly; a reduction is made for shared rooms. Extras are personal laundry, wines, and special medicines—required and special nursing, if required.

On the same estate there is also situated the Maitland Cottage Sanatorium, which has been established to provide open-air treatment for six patients who are unable to afford the charges at most existing sanatoria. The cottage and the grazing (10 acres) and the buildings have been given, but the working expenses have to be met either by patients’ payments or public subscriptions. The cottage, which has been specially constructed, is a wooden building on brick foundations. The accommodation for patients at present consists of three bedrooms, one single room—one to be shared by two—and one large room for three patients, with a dining and sitting room in the south-west aspect, both surrounded by fields and distant woods. Shelter from wind and rain is provided by verandahs and shelters. It is intended that the ground belonging to the cottage shall be utilised in developing light occupations for the patients.

All payments by or on behalf of patients must be made monthly in advance. Patients are not usually admitted for a less period than three months, and six months is generally considered desirable. No patient can be admitted without a medical certificate filled in by the doctor who has been attending the case. It is estimated that the cost of maintenance is about £35 weekly for each patient. This sum may be met by the patient or friends in return for a subscription of £5 10s., which, with an added payment of 8s. weekly by the patient, will provide for a three months’ course of treatment.

Dr. Esther Colebrook is now extending the accommodation for comparatively poor patients, and before long will be able to provide for the treatment of a small number of men of the working class.

It should also be added that a small four-roomed hygienic cottage at one end of the estate at the time of our visit was being used. The farm and gardens provide the sanatorium with poultry, milk and vegetables. The estate is so extensive and rich in conveniences that there is ample opportunity for considerable extension. It may also be noted that the country in the immediate neighbourhood of the sanatorium is rich in pastoral beauty, and in the immediate vicinity is much wild but very attractive common land and considerable extent of woodland offering numerous advantages for walks.

As regards access, Reading is the most generally convenient station, where patients are met by carriage.

The fare is 6s. 8d. for first class, 4s. 6d. for second class, and 4s. 6d. for third class. For pony carriage without luggage the fare is 5s. 6d. For dog-carriage the fare is 7s. 6d. Heavy boxes are sent by the carrier. The sanatorium, although at first sight somewhat isolated, which, indeed, is one of its advantages, is readily reached from London, and is so centrally placed as to be conveniently approached from almost all parts of the country.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, NOVEMBER 13TH, 1903.

DR. FREDERICK TAYLOR, President, in the Chair.

CASE OF MYOSITIS FIBROSA.

Dr. FREDERICK E. BATTEN read an account of the following case of a boy, aged 6, the second of five children. He was healthy at birth, but when nine months old the mother noticed that the back was becoming rounded, and that the legs could not be straightened. The conditions gradually increased, and when he was aged 6 he was in a rigidly flexed position, and any attempt to extend the legs brought the trunk into a sitting posture. The head was drawn to the right side by extreme contraction of the right sterno-mastoid, and the recti abdominis were contracted and of cartilaginous hardness. The upper and lower extremities were also contracted in a flexed position. There was no evidence of any disease of the nervous system. All the muscles on which the contraction was not extreme reacted to a weak faradic current. No relaxation of the contracted muscles occurred when the boy was placed under chloroform. The pathological examination of the nervous system revealed nothing abnormal. With regard to the muscles, the right sterno-mastoid was almost completely converted into tendon, fully one-half of the whole bulk of the recti abdominis were tendinous. In the muscular portions of these muscles and in the other muscles of the body examined there was a very considerable amount of fibrous tissue between the individual muscle fibres, many of which were atrophied and showed considerable degeneration. No factor could be found to account for the disease. The relation of the malady to myositis ossificans was dealt with, and it was mentioned in support of this view that the great toes were shorter than the others. The author favoured the view that there was a relative increase in tendinous structure owing to the contraction of the fibrous portion of the muscle. The paper was illustrated by lantern-slides and drawings.

MEASLES WITH COMA.

Dr. Newton Pitt described the case of a medical
student, aged 19, who was in good health on March 10th, 1893, but he contracted a chill while watching a football match. The following day he felt ill, the temperature rising to 102°F. A typical measles rash then appeared, and on the 16th the urine had to be drawn off. The next day his condition was critical, the pupils being widely dilated, and incontinence of urine was present. The optic discs were normal. Pulse, 110; temp. 103°F. He became comatose, and feeding was difficult. At this stage the pulse dropped to 60, but the temperature subsequently ran up to 102°F. The rash faded, and he gradually came back to consciousness, ultimately making a good recovery. During convalescence, he suffered from considerable insomnias for some months after his memory was defective and reading was apt to bring on headache. Dr. Pitt was unable to find anything exactly like this case in the literature, though there was the well-known case of Sir Thomas Barlow, of a man, aged 23, who became drowsy on the fourth day and died with respiratory paralysis. The question was whether the present case was anything more than a severe toxemia, such as a slight degree of encephalitis in an unimportant region of the brain. The incontinence of urine and faces rather pointed to the latter view.

Dr. Alexander Morison alluded to the case of a girl, aged 10, who was comatose with sluggish pupils, in which a similar condition was observed with immediate improvement in the comatose condition. When the bronchitis subsided, a measles rash appeared. The child died. Such a case justified the popular belief that the cases which present a full eruption early do the best.

Dr. William Hunter described a similar case occurring in scarlet fever, in which he considered that the possibility of a local encephalitis being produced by a toxic condition was well borne out.

Dr. Pasteur read the notes of a case of pernicious anemia with unusual features. The patient was a well-built man, aged 24. He had always enjoyed good health until three weeks before his admission into hospital. He was profoundly anemic with sallow complexion, and some blood was oozing from the gums. His teeth and mouth were in good condition. There was slight enlargement of the heart with haemorrhagic thrills. He had also double hemorrhagic neuro-retinitis, and he had some vomiting. The evening temperature was only slightly increased. The blood exhibited marked oligochromia with a relatively high colour-index with well-marked leucopenia and a relative lymphocytosis. The leucocytes numbered 2,000 ten days before death, which occurred exactly seven weeks after the onset of the first symptoms of faintness. No nucleated red blood corpuscles were seen, nor was poikilocytosis observed at any time. The urine was 1012 sp. gr., and was free from albumin or sugar. Sections of the liver after death gave a marked Prussian blue reaction. The spleen gave a slight reaction and the testis a very marked one. Chemical analysis showed that the amount of iron yielded by the liver was more than six times the average, and that it exceeded that obtained from the spleen. The chief features which rendered the case unusual were the absence of nearly all the changes of blood changes, the short duration of the illness, the marked changes in the fundus, and the presence of iron-containing pigment in the testes.

Dr. William Hunter said it would have been interesting to have known the state of the bone-marrow in this case, as he did not consider that the blood changes were those usually associated with the true Addisonian form of pernicious anemia. The absence of poikilocytosis was particularly an unusual feature. The sudden onset, the nature of the blood changes would rather incline him to place the case among that group of anemias of septic origin.

The case referred to a similar case of a man who did not die in the hospital, in whom there was great oligochromia, and also a definite septic focus in the shape of a fistula leading from the gums to the palate. A noteworthy point in connection with the case was that when the sepis was detected there was a sudden rise in the number of leucocytes.

Dr. Pasteur replied that he was unaware of any septic trouble in his case, and that his diagnosis was based more especially on the post-mortem findings in the liver and spleen.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
PATHOLOGICAL SECTION.
MEETING HELD FRIDAY, NOVEMBER 6TH, 193.
Dr. Pitt referred to a similar case of a man who did not die in the hospital, in whom there was great oligochromia, and also a definite septic focus in the shape of a fistula leading from the gums to the palate. A noteworthy point in connection with the case was that when the sepis was detected there was a sudden rise in the number of leucocytes.

Dr. Pasteur replied that he was unaware of any septic trouble in his case, and that his diagnosis was based more especially on the post-mortem findings in the liver and spleen.

The President, H. C. Earl, M.D., in the Chair.

The President delivered an address on the CYTOLOGY OF SEROUS AND SHTURED EFFUSIONS. He described the methods of obtaining and making microscopic preparations of the cells from effusions, and alluded to the difficulty that sometimes arises in distinguishing the class to which the cells belong, on account of the alterations they undergo after lying a long time in an effusion. He then related the results Widal and others got by cytological examination of effusions from the pleura, pericardium, peritoneum, of a circular fluid and of hydrocele fluid, as well as of the cerebro-spinal fluid. He considered that the diagnostic value of a predominance of lymphocytes in a pleural effusion, as a sign of its tuberculous nature, was very great, but that the cytological examinations of pericardial and peritoneal effusions were not sufficiently numerous nor sufficiently consistent to warrant any precise conclusions at present. He further considered that cytological examinations of fluids from joints and from hydroceles had given results of some diagnostic value, and that an increase of cells with predominance of lymphocytes in the cerebro-spinal fluid was in cases of meningitis of considerable value as denoting the tuberculous origin of the affection, and discussed the value of lymphocytic and polymorphonuclear formule of the cerebro-spinal fluid in other affections.

ORBITAL TUMOUR.
Mr. Arthur Benson and Dr. Langford Symes showed a tumour removed from the apex of the orbit of a woman, aged 48, full notes of which will be found on page 558.

Mr. Story said that the curious respiratory murmur heard over the affected orbit and its walls was to him the most interesting and obscure part of the case. Dr. Travers Smith and Professor O'Sullivan also spoke, and Drs. Benson and Symes replied.

ANEURYSMS OF CEREBRAL ARTERIES.
The President exhibited a brain with small aneurysms on various cerebral arteries. The Section then adjourned.

LIVERPOOL MEDICAL INSTITUTION.
MEETING HELD NOVEMBER 5TH, 1903.
Rushworth Parker, Esq., B.S., F.R.C.S., President, in the Chair.

Dr. James Barr described his method of treating pleural effusions.

After removal of the fluid, 40 to 60 minims of adrenaline chloride, 1-1,000, were used in nearly all cases with invariable success. In ascites the method was not so successful. He also described an apparatus for the introduction of an aseptic air into the pleural cavity.

Mr. F. T. Paul reported several cases of pylectomy.

Two, operated upon in extremis, died. The other three recovered: (1) a woman, aged 56, with extensive cancer of the pyloric end of the stomach, died six months later from recurrence; (2) a man, aged 46, with an early cancer; and (3) a woman, aged 56, in which the tumour proved to be an inflammatory mass. The two latter cases were so far in excellent health.

Mr. Paul also showed a man with carcinoma of the pylorus, who had improved so much after gastro-enterostomy that he (Mr. Paul) proposed to excise the growth.
The President, Dr. Wyatt Wingrave, in the Chair.

The following officers were elected for the ensuing year:—President, Mr. Bark, of Liverpool. Vice-Presidents, Dr. Robert Woods (Dublin), Dr. Lamb (Birmingham), Dr. George Reid (Edinburgh), Dr. Horne (Metropolitan). Dr. Wyatt Wingrave (ex officio), Dr. Hawthorne, Mr. Chichele Nourse, Dr. P. H. Abercrombie, Dr. Jobson Horne; (extra-Metropolitan), Dr. Fullerstone (Glasgow), Dr. Lodge (Bradford). Hon. Treasurer, Dr. Percy Jakins. Hon. Secs., Dr. Andrew Wylie and Mr. Stuart-Law.

Dr. Wingrave, the retiring President, vacated the chair in favour of the new President, Mr. Bark.

The following two gentlemen were elected Fellows of the Association:—Charles Edward Pepper, M.B., proposed by Dr. Macintyre, seconded by Dr. P. H. Abercrombie; David Robert Powell Evans, M.R.C.S., proposed by Dr. Nelson, seconded by Mr. Atwood Horne.

The following clinical cases were shown:—

Dr. Wingrave: A case of persistent superficial nasal hyperæmia cured by removal of adenoïds, in a whole, considered a close case.

Mr. Mayo Collier, speaking of this case, referred to several similar cases of his own where improvement had followed turbinal cautery.

Dr. Dundas Grant spoke of a similar case where he had scarified and applied pure carbolic acid with excellent results. He thought that the vestibular portions of the naso fossæ ought to be more carefully examined in such cases, as follicular abscess was a case of red nose.
DR. WINGRAVE: A case of facial and palatal paralysis following diphtheria in a child, the subject of chronic suppuration of the middle ear.

DR. KELSON: A case of (?) tuberculous nasal disease in a boy, aged 8.

Mr. Mayo Collier was inclined to regard this case as probably of a strumous nature.

Mr. Stuart Low thought the case was tuberculous.

Dr. Fred. Spicer: A case of accessory tragus (bilateral).

Dr. H. S. Barwell spoke on the morphological interest of such cases, and also Dr. Wingrave, who rather considered the nodules as belonging to the helix, and not the tragus.

Dr. Dundas Grant: A case of fibroma of the naso-pharynx in a boy; the operation for the removal of the growth was attended by remarkably little bleeding, and was highly successful.

Mr. Mayo Collier, speaking on this point, recalled a case of the late Mr. Lennox Browne, where also the hemorrhage had been slight.

Mr. Mayo Collier: A case of frontal sinus disease, in which recurrence of suppuration had followed the external operation, and was only cured after removal of the greater part of the middle turbinal.

Dr. Dundas Grant strongly insisted on the principle that in these cases the anterior part, at least, of the middle turbinal should be removed first of all before resorting to the external operation, and that in many cases the performance of this partial turbinotomy would obviate the necessity for the much more external operation.

Dr. H. S. Barwell and Dr. Jobson Horne spoke on this case, and also Mr. Bark, who instanced cases where, in his opinion, a nasal operation had prevented the necessity for the radical operation for frontal sinus disease.

Dr. Fred. Spicer also was in favour of removing part of the middle turbinal in cases of frontal sinus disease.

Dr. Dundas Grant: A case of epitheloma of the external auditory meatus in a woman, aged 26.

Dr. Bark spoke on the youth of Dr. Grant's patient, and recalled the case of a patient of his own, a woman about the same age, who had epitheloma of the osophagus.

Dr. Jobson Horne: A case of papilloma of the vestibule of the nose.

Mr. Mayo Collier thought this was very likely an instance of a fungating sebaceous cyst.

Dr. Wingrave regarded it as a limbrated papilloma with stratified epithelium.

Dr. Kelson considered this case one of simple papilloma, so did the President.

The following microscopic specimens were shown by Dr. Wingrave:—(a) Nasopharyngeal fibroma, simulating adenoids; (b) malignant ulcer of oro-pharynx; (c) epitheloma of external auditory meatus; (d) epitheloma of pharynx and tonsil.

The following communications were made:—

An improved screw maxillary antrum perforator, by Dr. Haslam.

Notes of an unusual case of empyema of the maxillary antrum, by Dr. Perry Goldsmith (of Canada).

Concerning radium (with specimen), by Mr. Chichele Nourse.

Notes on a case of rhinitis caseosa, by Mr. Bark.

A selection of instruments were exhibited by Messrs. Mayer and Meltzer.

CORK MEDICAL AND SURGICAL SOCIETY.

MEETING HELD WEDNESDAY, NOVEMBER 11TH, 1903.

J. Cotter, M.D., F.R.C.S.I., President, in the Chair.

Dr. W. Ashley Cummins showed viscera from a case of heart disease in a woman, aged 30. The heart was enlarged, the aortic valves were thickened and puckered, and almost cartilaginous in hardness, the mitral valve was also affected, but the most remarkable feature was extreme stenosis of the tricuspid orifice, which barely admitted the tip of the little finger. The lungs showed haemorrhagic infarcts, and the "nutmeg" condition of the liver was well marked.

Dr. C. Velverton Pearson showed a myomatous uterus which he had removed from a woman, aged 50, by supravaginal hysterectomy.

Dr. Pearson also read notes of a successful case of removal of a gall-stone from the common bile-duct for persistent jaundice. The patient was a woman, aged 42, and the jaundice had lasted six months. As soon as the incision was made the calculus could be palpated in the common duct. All the stones were passed, the duct incised, and the calculus, which was of the size of a large marble, was easily removed. The patient made a rapid recovery, the jaundice quickly disappearing.

Dr. H. R. Townend read notes of a case of acute obstruction in a woman, aged 28, due to a loop of small intestine being dragged down into the pelvis and kinked by adhesion to the fimbriated extremity of the Fallopian tube. The adhesions were divided and the patient made a good recovery.

FRANCE.

[FROM OUR OWN CORRESPONDENT.]

PARIS, November 14th, 1903.

UREMIA.

It frequently happens, says Professor Huchard, that the most simple things penetrate the mind with most difficulty; because they are simple no attention is paid, and yet in medical practice it is frequently by the most simple means that the best results are obtained. It is thus that the hydric treatment of uremia is attended with the best advantage to the patients.

M. Renon pointed out three or four years ago the efficacy of the water treatment in eclampsia, and he was followed by Bar, Mathieu, and others. But for a long time conviction could not be shaken in the milk diet, yet how many patients, in spite of the classical régime, suffer from attacks of uremia? In such cases the milk should be suppressed and replaced by water, a half a pint every two hours, or Eau d'Evian, as in the treatment of enterocolitis (acute).

For patients afraid of absorbing such a large quantity of water, diuretic infusions might be ordered from time to time, slightly sweetened. How long should the hydric treatment be kept up? M. Renon prolonged it three or four days, and prescribed afterwards a return to the milk, rice-water and vegetable soup. In general, two or three days of the water treatment are sufficient. A drastic purgative is given on the first day of the treatment. After the third day food is prescribed, more as a tonic to the heart than for any other consideration, as a too long abstinence might weaken that organ.

During the hydric treatment M. Huchard gives small doses of crystallised digitalin (1-10 milligramme) for ten days, in granules or solution (1-1000; 5 drops represent 1-10th of a milligramme). The hydric treatment should be repeated one or two days every week, especially if the dyspepsia shows signs of returning.

TREATMENT OF SCROFULA.

During the winter months, and if the stomach can support it, cod-liver oil. In summer, syrup of tannate of iodine or other anti-scorbutic preparation. At the two principal meals:—

Iodide of calcium . . . 1 drachm
Lime water . . . 2 ounces
Peppermint water . . . 4 ounces
A teaspoonful in a little water. Every two days a bath of—

Common salt . . . . 2 lb.
Carbonate of soda . . 4 ounces
Amidon . . . . . . . . 10 ounces

Every day dry rubbing over the whole body, followed by the following mixture:—

Eau de Cologne.
Spirit of lavender.

The alimentary régime should be rich in fats and phosphates (milk, eggs, farinaceous compounds, meat, chicken, dry vegetables, &c.). The children should be sent to the country or the sea-side, or to such waters as Bourbonne, Barèges, Bourboule, Royal, Châlet-Guyon.

Neurasthenia.

This modern affection, which has invaded all classes of society by reason of the struggle for existence and the general rush of every-day life, has been the object of careful study on the part of practitioners. M. Albécides the following treatment in this complex malady:—

Suppress as much as possible the cause of the nervous exhaustion by withdrawing the patient from all business and enjoining strict rest of mind and body. The patient, who should take as much exercise (walking) as possible without fatigue, should go to bed early and rise late. Every two days an ordinary bath of a quarter of an hour, followed by rubbing or massage. Every two days a sance of static electricity. The patient, seated on an isolating stool, is placed in communication with the negative pole of an electric machine and becomes charged thus with electricity.

As tonics: before the repast, twenty drops of the following preparation in water:—

Tincture of nux vomica . . . . 1 drachm
Tincture of conine . . . . . . 1 drachm
Tincture of Coloombo . . . . . . . 1½ drachm
Tincture of gentian . . . . . . . . 14 drachms
Ess. of aniseed . . . . . . . . . . . . 10 minims

During the meal half a wine-glass of—

Arseniate of strychnine . . 4 grains
Glycerophosphate of lime . . 6 drachms
Syrup of bitter oranges . . . 4 ounces
Quinine wine . . . . . . . . . . 12 ounces
Kola wine . . . . . . . . . . . 12 ounces
Coca wine . . . . . . . . . . 12 ounces

Germany.

[FROM OUR OWN CORRESPONDENT.]

At the opening meeting of the Society for Innere Medizin, Hr. F. Lesser spoke on Iodism and its Prevention. He said it was generally understood that with an acid reaction of the organism free iodine was split off on the administration of iodine combinations, and that in this way iodism or symptoms of iodine poisoning were caused. With a view of avoiding this splitting off, sod. bicarb., extern. belladone, sulphanilic acid, &c., were given without any special effect. Many theories had been brought forward as to the kind of decomposition, but up to the present free iodine had not been demonstrated in the system. It was believed that the free iodine at once combined with the albuminous bodies. With the exception of the thyroid, no organ contains any iodine combination, but only inorganic salts were identified. It was a question whether potassic iodide without any splitting up did not give rise as such to the symptoms, just as iodiform, without freeing of the iodine did. Iodipine, which alone of all the organic iodine preparations retained its place in the market, produced no iodism when injected subcutaneously: when given by the mouth it produced the same poisoning symptoms as potassic iodide. In both instances there was a change, and excretion of potassic iodide took place. Whilst, however, when given by the mouth resorption could be shown in a few minutes, this only followed gradually when given subcutaneously, from the reserve of iodine fat. In accordance with this iodine was demonstrable for six months after subcutaneous administration of ten days. A woman who always showed iodism after taking potassic iodide did not show it when iodopine was given subcutaneously, but she got it at once when the iodipine was given by the mouth. The gradual and steady resorption of iodipine injection could be obtained after administration of potassic iodide if given in repeated small doses. Instead of giving a tablespoonful three times a day, a tw spoonful should be given hourly. The therapeutie effect was the same, and iodism was almost always avoided.

Hr. Bratt thought it contradicted all pharmacological laws that so active a poison as potassic iodide should pass from the system unchanged. Iodine, indeed, could not be demonstrated in the system, but it formed a combination at once.

Hr. Fürbringer observed that he had pointed out that the body was never flooded with free iodine and such a thing need not be feared.

Hr. Heller thought that the lodo-albumen preparations were an advance. He had employed them with a large number of patients, and had never seen iodism after using them.

Hr. Strauss had seen good result from the simultaneous administration of ext. belladone and sod. bicarb., when using potassic iodide. With iodalbic acid and iodipine given internally the onset of iodism was delayed. Alcoholics seemed specially disposed to iodism.

Hr. Saalfeld had observed that people that could not bear potassic iodide bore lodoalbumen preparations well. In club practice he specially recommended tincture of iodine.

Hr. Lesser, in reply, observed that the theory of the splitting off of iodine was a purely arbitrary one, and one that could be dispensed with.

Austria.

[VON OUR OWN CORRESPONDENT.]

Vienna, November 14th, 1903.

The Action of Thermal and Mechanical Influences on the Circulation.

Pick has written a long article on the influence of thermal and mechanical agents in toning the vessels and hastening the circulation.

The subject has given rise to more contradictory results than any other treatment adopted, owing, no doubt, to the complex nature of measuring the results. Pick has adopted the direct measurement of the current, both in quality and quantity, by defibrinating, &c. This operation requires great care and much detail work to defibrinate the blood and return it to the animal after measuring the flow from both vein and artery by means of canals inserted into the vessels. In every case the arterial blood pressure was always above the average after massage, thus proving the tonus between artery and vein. His results from this method of procedure were:—

(1) The
effects of massage of the extremities accelerated the hematic current and distended the vessels generally, thus reducing the tonus of the vessels. (2) The constant effect of massaging the abdomen hastened the blood current, lowering the tonus of the blood-vessels in the mesentery, at the same time slowing or retarding the circulation through the brain. (3) Passive movement of the extremities had different results; rapid extension of one leg increased the flow in the femoral; if both legs were extended it also increased the flow in the brain. (4) The thermal results gave a dilatation of the vessels in cold as well as heat, that is, the circulation became increased, and dilatation immediately followed. (5) Thermic friction acts on the vessels through the nerve system, and is as powerful as direct heat to the walls of the vessels.

**Subacute Spino-Cerebellar Ataxia.**

Süsswein related a case of subacute spino-cerebellar ataxia at the Gesellschaft, which excited considerable interest. The patient was a female, aged 71, who gradually became weak in the legs, walking with great difficulty, and suffering from vertigo and vomiting. The phenomena appeared one morning rather suddenly, soon followed by the ataxia, which was less pronounced for a few days later. Within five months from this time she died.

The post-mortem revealed a lesion in the cerebellum and spinal cord. The disease was principally confined to the posterior columns of the cord and the intermedullary part of the posterior roots, although there was a slight change to be found in the anterior root and column.

The parts most affected were the sacral, lumbar, and lower parts of the dorsal regions. In the cerebellum a few centres were found having the appearance of acute degenerative change.

The etiology may be accepted as arterio-sclerosis, although marasmus and tuberculosis cannot be excluded, as he considered senile marasmus and arteriosclerosis reduced the vital resistance, and thus facilitated the action of the tuberculous toxin.

**Abscess in the Brain.**

Hugo Frey showed a young patient, aged 12, who, after an acute attack of inflammation in the middle ear, developed an abscess in the temporal lobe of the brain. Recognising the danger, the cranium was opened and incision made into the abscess. Recovery was complete.

**Vascular Crisis and its Relation to Gastric and Abdominal Crisis.**

Pal opened an important discussion on the relationship of the "grande crise gastrique" of the tabetic to other vascular tensions met with in daily practice. The high tension in all cases precedes the attack; although it may not be immediate, yet it usually synchronises with its rise, while the pain subsides with its fall. The reduction of this tension by the assistance of drugs may often prevent the attack.

Feders thought that, generally speaking, the increase of pain or colic, as it is sometimes called, was only an increased form of blood pressure. We had often similar colicky pains in influenza, resembling the lancinating pain of the tabetic, which was instantly relieved by the lowering of the blood pressure. He had himself made many examinations of the tabetic, and concluded that the high blood pressure was the cause of the pain.

Pal remarked that the blood pressure in the tabetic is the expression of different causes at the time of the vascular crisis. Winternitz added that his experiments in the gastric crisis were also due to high pressure, as the lancinating pain was instantly removed by a lowering of the tension. Pal again interposed by saying that the results of Stricker proved that the posterior roots possess the centres of vasomotor dilatation, and when morbidly affected may be the cause of the vascular tension.

**The Operating Theatres.**

**NORTH-WEST LONDON HOSPITAL.**

**Latent or Intermittent Nasal Obstruction.**—Mr. Mayo Collier operated on a series of these cases of latent or intermittent nasal obstruction for the relief of chronic nasal and post-nasal catarrh, with, in some cases, deafness, morning cough, and hoarseness. Before operating Mr. Collier brought forward one typical case, and whilst demonstrating to those present, said: "This girl comes here and is anxious for me to see her because she says I cured her sister, who was suffering from a like condition. She says she always has a cold. She is hoarse in the morning and has some cough during the early part of the day, which disappears towards noon. She always has more or less discomfort in the throat, and finds that food is not so comfortable, and easily becomes sore. A good deal of mucus, which is difficult to remove, passes down the hind the palate. She says her digestion is not good; she feels so distended after meals. With a bad cold she is always deaf, and is troubled with noises in the ears." Mr. Collier said this was a delightfully typical picture of a very common affection. He was coming next to demonstrate the interior of the nose. He said that those present could see that at the present time the nose was perfectly free and patent, and that the most ardent obstructionist could not claim this (at the present moment) as a case of nasal obstruction. The lower turbinal bodies were standing at least half an inch from the septum, and one could actually see the pharyngeal wall through the lower meatus, and nothing abnormal, except congestion and catarrh, could be detected anywhere. Mr. Collier asked those present to note that a well-marked hollow existed on both sides of the septum, opposite the lower turbinal bodies, forming an exact cast of them. With this present complete freedom of nasal passage it was strange to say, this patient complains that half her time she is completely blocked and often cannot breathe at all through the nose. She asserts that when she wakes in the morning she is quite unable to breathe through the nose, and it is not until she has been up and dressed and has walked about that the passages become free. Mr. Collier said this was a condition of things that few rhinologists had recognised, yet this form of obstruction was more complete and more potent for harm than obstruction due to bony or cartilaginous outgrowths, polypi, or what not, these latter seldom producing such complete obstruction as in the latent form. Mr. Collier said the post-nasal catarrh, the morning deafness, cough, &c., were all directly due to the fact that the nose was not free and patent. Restore the functions of the nose and the train of symptoms just enumerated will disappear without further treatment. In operating, Mr. Collier said he strongly objected to any operations for removal of the turbinal bodies. All that was requisite was to pin down the erectile mucous coverings of the turbinals at their most prominent parts with the galvanocautery. He next introduced some 20 per cent. solution of cocaine, followed by some adrenaline solution on a probe with cotton wool. The parts being completely anaesthetised, he introduced the galvanocautery and consolidated the mucous membrane and.
subjeent tissues, down to the perioistum over a space equal to the cross-section of a large pea. Mr. Collier said the cicatrix produced by this procedure would hold the glands in place and the cautery would brace up the whole lining membrane of the nose and help to rid the patient of her chronic catarrh. The after dressing consisted simply of the application of some menthol cocaine and parolene solution introduced with an atomiser. He recommended the avoidance of severe exertion for a few days, the avoidance of all alcohol, the use of an extra pillow or two under the head at night, and the sparing use of the handkerchief. Mr. Collier operated on one side only, and said he should repeat the procedure on the other side a week hence. No pain was experienced during the application of the galvano-cautery, and none would be felt when the effect of the cocaine wore off.

**GREAT NORTHERN HOSPITAL.**

**Case of Lymphadenoma.**—Mr. Peyton Beale operated on a man, aged 39, who gave the following history: He was a retail butcher by trade, and three years ago began to suffer from an enlargement of the lymphatic glands on both sides of the neck; the enlargement progressed steadily, but slowly, and soon became associated with marked anaemia and lassitude, the temperature rising at night to about 100°. About a year ago he was taken into a hospital, where the glands were diagnosed as tuberculous, and he was told that it was not advisable to have an operation performed. As far as could be ascertained this advice was founded upon the manner of the glands and the fact that every one was enlarged. He was given a large quantity of arsenic with iron and other tonics, and was sent home at the end of about a fortnight. His condition before operation was as follows: Very anaemic, rapid, feeble pulse, temperature at night 100°, by day 99°, never dropping to normal. There was an enormous mass of enlarged glands on each side of the neck extending from the mastoid process to the clavicle, and as far forwards as the symphysis of the jaw; a few enlarged but freely movable glands in both axilla and groins; no apparent enlargement of liver, spleen or abdominal glands; urine normal. As the patient was rapidly becoming weaker it was decided to remove the glands in the neck as radically as possible, the right side being attacked first, as the mass there was slightly larger than the mass on the other side. An incision was made from the mastoid process to within an inch of the middle of the clavicle, and to divide the spinal accessory and many of the superficial cervical nerves. The glands had then to be dissected off the sheath of the vessels both in front and behind. There was a considerable amount of bleeding, involving the application of about thirty ligatures. The wound was closed, a gauze drain being inserted at the lower end. A fortnight later the same procedure was adopted on the left side of the neck. Mr. Beale said that at least two more operations would be required to clear out the glands below the jaw. He remarked that he had operated on several cases of this kind previously, in some of which there had been typical enlargement of the spleen, and in all more or less temperature; one had died a few days after an extensive operation, but as far as he knew the others had all lived for some years, one for five years, dying eventually from the same disease involving all the glands in the abdomen and mediastinum. He referred to cases which had been proved by microscopic examination of the glands to be lymphadenoma. He said that at least three of the cases were "butchers," by trade, and all were under thirty-five years of age. He believed that radical removal of the glands which were earliest affected was followed by a period of stasis in the enlargement of the other glands; therefore it was unadvisable to operate on such cases as soon as possible, providing, of course, that medical treatment had failed to produce any marked effect. He pointed out that these patients seemed to bear operation wonderfully well, even though there was always some temperature, marked anaemia, and very considerable general debility. At the time of the second operation the skin edges of the first wound were healed, with the exception of the drainage aperture, from which there was practically no discharge. The patient's general health was at the same time so much improved that he was able to walk about the ward, whereas prior to the first operation he had been unable to leave his bed for a fortnight. Iodide of potassium and iron in small doses were being administered daily.
another cattle-maiming outrage was committed in the neighbourhood of Wyrley, and threatening letters sent to the police and others. The trial resulted, however, in the conviction of Edalji, who was thereupon sentenced to seven years' penal servitude. That happened some weeks ago, and further outrages upon cattle have taken place in the neighbourhood, and more threatening letters have been sent. On these facts alone there appears to be strong ground for urging upon the Home Office the necessity for a revision of Edalji's sentence. Apart from purely legal considerations, however, comes the medico-legal claim for revision, which is in our opinion overwhelming. Consider the position if we assume this young lawyer to have been guilty of these atrocious and purposeless crimes. Could a sane, educated man, brought up in a sound moral atmosphere, have stolen from his bedroom at dead of night to slash open the bellies and cut the throats of horses and cows and donkeys? The conclusion is irresistible that any man who acted in that manner without any obvious political or personal motive must be insane and unaccountable for his actions. Edalji was convicted of acting in that brutal and purposeless way, therefore he must be insane if the finding of the law be correct. His proper place, then, under such circumstances, we emphatically claim to be a criminal lunatic asylum and not a convict prison. If the administration of justice in this country is not to be rendered an object of scientific contempt, the state of mind of the convict Edalji should instantly be made the subject of inquiry by a body of the most experienced alienists that the country can command. From our own point of view, the whole of the series of outrages at Wyrley is in all probability the work of one hand. It is, scientifically speaking, incredible that two or more persons could combine together for the perpetration of such absolutely cruel and senseless crimes. The statements in the letters that a gang is concerned may quite probably be a part of the diabolical cunning exhibited throughout the affair. Indeed, the existence of that very dexterity in eluding detection points to a common characteristic of certain forms of insanity. The White-chapel murderer—the notorious "Jack the Ripper"—was never caught, in spite of the fact that half London was in a state of panic over his crimes, and the whole resources of the police were called into requisition to capture the criminal. In that case the offender was almost certainly a homicidal lunatic, who chose as his victims women of the "unfortunate" class. In the Wyrley outrages the criminal has fixed on cattle and horses for his prey, and is also, probably, the victim of a partial moral mania akin to the homicidal form. Under the peculiar psychological circumstances that have surrounded this trial we trust that a determined effort will be made to obtain an intelligent investigation of the case, and, if necessary, a revision of the sentence. As already stated, we feel no hesitation in demanding that reconsideration on medical grounds alone. It would be hardly possible to imagine an instance where the desira-

ARTICLES.

MEDICAL MEN AND MOTOR CAR REGULATIONS.

A certain degree of apprehension has arisen in the minds of medical men who practise in the country, and who use, or propose to use, motor cars, as to the effect the new regulations may have upon the general utility of the motor car. If a medical man is under no circumstances to be allowed to exceed the maximum speed, if certain roads in country districts are to be barred to him, and if he is not allowed to leave his car on the roadway outside the house of a patient, then it is obvious that many of the advantages of motor cars are at once abolished. Cases have already occurred in country districts in which the fact that the medical man was able to traverse a large stretch of country at a high speed practically saved the life of a patient, and such cases are bound to be of relatively common occurrence. They are, however, sure sooner or later to bring the medical man within the clutches of the law, and under such circumstances what will the law do? It has been suggested in a contemporary that the effect of the clause which permits the local authorities to close any road not exceeding sixteen feet from hedge to hedge to motor vehicles may be a serious one for country medical men and may necessitate long rounds. This might be the case in a few isolated instances, but there are very few roads of such a size in which the use of a motor car would be dangerous, and unless this could be proved to be the case the road could not be closed under this clause. In the long run, such a clause is more likely to lead to the widening of roads than to their permanent closure to motor cars. A case involving a question of greater importance occurred recently in the neighbourhood of Dublin, where the police prosecuted a well-known medical man for causing an obstruction to the thoroughfare by leaving his car standing outside the house of a patient without any person in charge, the contention of the police apparently being that anyone might get into the car and cause it to start. Dr. Wright, the medical man in question, proved that he had taken all necessary precaution to render it impossible to start the car. It also appeared that the car was four feet six inches in width, while the roadway was twenty-four feet in width, so that any direct obstruction to traffic was almost impossible. The absence of a driver was accounted for by the fact that Dr. Wright having to start off early in the morning to visit an urgent case, was obliged to leave both his driver and his breakfast behind. We refer to the evidence in this case particularly, because it is difficult to say whether any special factors led to the result of the prosecution, and whether the magistrate would, on a subsequent occasion, take a different view. The magistrate expressed the opinion that the police were absolutely justified in bringing the summons, both in the interests of the public and of the medical man, but he dismissed the case. The
decision leaves the position of medical men who use motor cars in an eminently unsatisfactory condition, inasmuch as it does not make it plain as to whether a medical man may or may not leave his car outside the house of a patient. If he cannot do so, and if he must always be accompanied by a chauffeur, the value of motor cars is seriously diminished. The fact that the prosecution will doubtless be usually dismissed is of little moment, when the valuable time lost in attending the Court is taken into consideration.

KING EDWARD VII. SANATORIUM.

It is hardly a congenial task to strike a discordant note amid the chorus of congratulation and good wishes that have accompanied the inauguration of the King's Sanatorium. If we feel compelled to do so it is because we fear that the attention which has been directed to the scheme and its details may induce others who are planning the building of sanatoria to follow on the lines that have been adopted at Midhurst. Let us say at once that we have nothing but admiration for the generosity of Sir Ernest Cassel, and for the discrimination and kind-heartedness of the King himself. The spirit that moved his Majesty to devote the sum presented to him to the purpose he had at heart is that which we have been accustomed to associate with his wise and kindly rule, a rule that is establishing a lofty and noble standard that his successors will find it hard to live up to. Having decided on the object to which to apply Sir Ernest Cassel's gift, the King placed himself in the hands of an Advisory Committee composed of men of high standing, and on their recommendations he has acted. Now, the only criticism we have to offer on the constitution of the Committee is that it does not contain the name of any medical man with personal experience of internal sanatorium administration and therapeutic routine, and it is to this defect that we are inclined to attribute the error that we conceive to have been committed. The Committee has not acted precipitately, but, on the contrary, has been at great pains to ascertain the most advantageous way of laying out the money provided, and to erect a model sanatorium. It is, therefore, likely that this institution will be taken to serve as the pattern on which will be fashioned the many sanatoria that are being projected all over the country. It is here that we believe the danger to lie. No words of ours can affect the building of the King Edward VII Sanatorium, but we would ask county councils, boards of guardians, and charitable bodies who have similar institutions in view to pause and consider whether a more economical and efficient plan could not be adopted. The accumulating experience of sanatorium physicians all points to the importance of providing the largest possible supply of pure air for each patient, and the greatest possible separation of patients from each other, together with the maximum of sunlight. Whether it be in tenements, hospitals, or sanatoria, the aggregation of persons on a confined area is bad, and in no case can it be worse than in that of sufferers from pulmonary tuberculosis. If each patient could have an acre to himself he would be so much the better, but in practice, of course, such a separation is impossible. The point, however, to aim at is that each inmate of a sanatorium should be as far as possible isolated from his fellows under conditions that supply him with the best supply of air, sunlight, and protection from inclement weather. How are these desiderata to be practically combined in a sanatorium? We say, unhesitatingly, by the separate hut, or chalet, system. It cannot be denied that there are some inconveniences with regard to service and superintendence attached to this plan, but they are small and can be easily discounted by expert management. The extra working expenses have been calculated at only 15 per cent. more than those attendant on the block system of buildings. Let us turn to initial cost. We find that the King's sanatorium is to cost something £500 per bed for buildings alone, and this without severe disregard of anything approaching luxury. Comparing this with the cost of £50 for which a furnished chalet can be provided, and adding another £50 per chalet for its share in the common administration building, we find that it is possible to provide six times the number of beds on this system for the same capital outlay. To be quite fair in calculating the primary cost of an endowed institution, or one dependent partially on eleemosynary agencies, it will be necessary to add a sum representing the capitalised cost of a part of the 15 per cent. extra working expenses of the chalet system, the exact portion depending on the ratio between income from endowment or subscriptions and patients' payments. But even with this sum added to the initial cost, the requisite outlay on a sanatorium composed of chalets is only a third or a quarter of that needed for one on the block principle. Whatever may be said on the score of convenience in favour of this latter type of institution, we maintain that both from the point of view of economy and of therapeutics, the balance is largely in favour of the chalet. We would earnestly urge that these points should be carefully weighed by all persons interested in the open-air treatment of consumption.

Notes on Current Topics.

The Wyrley Cattle-Maiming Case.

The publication of our special editorial notice on the Wyrley cattle-maiming case has attracted considerable attention in various parts of the United Kingdom. In our leading columns of the present issue of The Medical Press and Circular will be found an article explanatory of the grounds on which the editorial notice of last week was founded. Since that article was written its main arguments have been confirmed in a remarkable manner by the independent opinion of Dr. E. G. Younger, a medical alienist whose authority upon a matter of this kind is of the highest. His view of the case, it need hardly be said, is closely reasoned and philosophical. As will be seen by a reference to our correspondence
columns, he suspects that the whole of the outrages, both before and after the conviction of Edalji, have been the work of a person suffering from some form of insanity, probably of the type either of moral mania or of imbecility. He completely endorses our view that supposing an educated young solicitor to have committed these purposeless maiming outrages on cattle, he would be fitted for a lunatic asylum rather than for a prison. Under these circumstances, it becomes, in our opinion, incumbent on the medical profession as a whole to demand "an inquiry into the mental condition of Edalji, who is now under a sentence of seven years' penal servitude."

We shall be glad to carry out the suggestion that a memorial signed by medical men should be presented without loss of time to the Home Secretary. Any readers willing either to sign such a petition or to obtain signatures from brother practitioners will find the necessary form accompanying our present issue.

Meat-Eating and Appendicitis.

Whenever a disease, by reason of its frequency of occurrence, is brought prominently before the notice of the public every possible effort is made in order to connect it with some fault in living or with some error of diet. This is only natural, for in many cases the connection is a real one, though more often, perhaps, the faddist poses while the scientist is crowded out. It is interesting to note that in a paper read before the Académie de Médecine of Paris by M. Chauvel it is stated that appendicitis is seen with comparative rarity among the military population of Algiers and Tunis as compared with that of France, the disease being nearly twenty times more frequent in the latter country. The rigorous discipline combined with an almost vegetarian diet is held to be responsible for this difference. In the discussion which followed the reading of the paper M. Lucas Champonnière upheld M. Chauvel in the theory which claims meat-eating as an etiological factor in the causation of appendicitis, and he laid stress upon the fact that the disease was most frequent among Europeans and Americans, who, it would be admitted, habitually consumed far too much flesh-foods. At the same time, he pointed out that other maladies, especially influenza, were rife among vegetarians, who, in many instances, seem to be placed in a less favourable position with regard to the power to resist the invasion of an acute specific fever. The rigid dietetician is, therefore, in somewhat of a dilemma. He must choose between influenza or appendicitis. According to the physician, there seems to be no end to the long list of terrible things which follow in the wake of "la grippe," while, on the other hand, we are equally assured by the surgeon that our appendices are useless encumbrances and veritable death-traps as long as they remain within the body. A moderate and mixed diet is the safest course to adopt to insure immunity from appendicitis and many other diseases.

The Bequest of a Corpse.

It is not often that a hospital has to refuse a bequest, but so it happened the other day. A man who died in a Bloomsbury boarding-house left his body by will to one of the London hospitals. Doubtless the lecturer on anatomy would have been glad to have availed himself of the gift, but the testator had disposed of that which did not belong to him. It has been decided more than once that there is no property in a corpse, and, therefore, it can be neither given, sold, nor stolen. There is a curious condition of community in which there has of necessity to be a certain trade in dead bodies for the purposes of anatomy, and it is probably only the public horror of anything like disrespect for the dead that accounts for the subject not being placed on a definite footing. For so long as surgery exists dead bodies will have to be found for the dissecting-room, and it is somewhat derogatory to the profession that the arrangements for acquiring subjects have to be carried on sub rosa. The chief source of supply is from the workhouses, which dispose of the bodies of unclaimed paupers to the medical schools. Every now and again there is an outcry in some union when the fact becomes known, and guardians are elected to oppose the practice. It would be far better in every way, and far more in accordance with the dignity of our profession, if the necessity of the supply of corpses could be definitely legalised, for surely the study of anatomy is one that deserves encouragement at the hands of society.

Divine Hygiene.

Dr. Adler, the Chief Rabbi, has frequently lectured on the sanitary provisions of the Mosaic law, and pointed out the hygienic trend of its provisions. Two large and interesting volumes have just been put forth by Dr. Alexander Rattray dealing laboriously and exhaustively with the same subject. From whatever source the Jewish legal code was derived—Dr. Rattray holds the view of direct Divine inspiration—there can be no doubt that for a rural or nomadic community no better scheme for the preservation and protection of health has ever been in force. Indeed, were the law-giver's directions followed out as far as circumstances permitted in modern towns, there would be much less sickness and misery. The chief factors in public sanitation are all treated of—food, drink, climate, disease prevention, burial and camping, and also a number of private matters of great moment that our hygienists have given but little attention to, such as personal cleanliness, mortality, marriages, rest and exercise. The marital relations of the sexes to each other were carefully defined by Moses, and it is much to be regretted that his salutary directions are slurred over nowadays by the prudery of the age. Nothing but good could come of their being widely known and followed. The interesting rite of circumcision, which the Jews shared with many of their neighbours in the East, is lucidly treated by Dr. Rattray, and many other interesting topics that are well worth further
discussion. Our own Public Health Acts cannot supply the same religious inducements to the people to observe them, nor do they provide the same stern penalties for law-breakers, but one might often wish that they were as well known and as much treasured as the Pentateuchal sanitary code has been for the last five thousand years.

Shell-Fish and Typhoid.

Since attention was drawn some years ago to the possibility of typhoid fever being conveyed by oysters, numerous cases of infection by that means have come under notice in various parts of the country. Various steps have been taken by oyster-dealers to guard their stock from contamination, but a great deal remains to be done before one can eat these molluscs without the uncomfortable feeling that there may be "poison in the pot." Oysters, however, are the delicacies of the rich, but the corresponding luxuries of the poor—melons, wheats and coxes—are just as likely, if not more so, to be contaminated by excrementitious matter, and several outbreaks have occurred through their agency. The London supply of these shell-fish comes chiefly from the creeks along the banks of the estuary of the Thames and the Essex shore, and it is comforting to see that—stimulated by the action of Dr. Collingridge—the Fishmongers' Company, who hold jurisdiction over the fish markets of the Metropolis, are forbidding the sale of cockles from Hadley Ray and West Shoebury. Samples from these places having been examined bacteriologically by Dr. Klein were pronounced unfit for human consumption, and the prohibition has not come too early to prevent cases of typhoid fever probably due to their use. The extent to which shell-fish is eaten by the poor in London is enormous, and the flavour is in some cases destroyed by boiling. It is, therefore, of the greatest importance that their consumption should be limited to those that come from places where care is taken that they are not contaminated by human excreta. The crucial difficulty that has never yet been surmounted is the identification of the shell-fish that has come from uncleanly impure sources. How rare the public to tell the one from the other in the absence of some distinguishing mark on the shell?

The Expectoration of Urine.

Many of the fluid excretions and secretions of the abdominal viscera find their way into the mouth, the act of vomiting being the most common and familiar example of the manner in which the contents of the alimentary canal are forced by regurgitation into the buccal cavity, from thence to be expelled from the body. More rarely, though of frequent occurrence, are fluid substances brought up by way of the respiratory passages. An hepatic or substernal abscess which has perforated the diaphragm and burrowed into the lung tissue, giving rise to the expectoration of purulent matter, is the best instance of such an event. The evacuation of urine per oram is such an exceedingly rare occurrence that a case of this nature exhibited by M. Taboulay before the Société des Sciences médicales de Lyons is worthy of attention. The patient, a man, aged thirty-four years, had been operated upon in April, 1902, for a large congenital hydronephrosis, chiefly on account of recurrent attacks of hematuria. As the ureter could not be reached, a large drainage-tube was inserted, which, as the wound healed, was gradually shortened until the patient left the hospital at the end of three months, still, however, with a short length remaining in the upper part of the wound. He did not return for inspection, but remained at his work until July, 1903, when he came back complaining of bringing up a urinous fluid by the mouth. The tube was found firmly fixed in the wound by a collar of phosphatic deposit, and, accordingly, a new incision was made. It was then seen that the tube had perforated the diaphragm and had opened the lung with the formation of a reno-pulmonary fistula. This was closed, and the man made a good recovery. One peculiar feature in the case was that the man was not specially troubled with cough, which is generally a marked symptom in most forms of fistulae communicating with the lung.

Massage as an Adjunct to Medicine.

One of the most common errors, from which medical men are by no means exempt, is to condemn wholesale a system merely because in isolated instances its exponents have proved themselves to be corrupt, fraudulent, or otherwise unworthy of support. The practice of medical gymnastics, including massage, has been viewed with disfavour, and is still so regarded by many practitioners, who, while recognising the good to be derived from careful rubbing and regulated movements, have had the ill luck to meet with masseurs or masseuses of questionable character who have sought to retain their patients under their own care. To anathematise these individuals as a class, many of whom are of gentle birth and superior education, would be about as sensible as to condemn all chemists because here and there one may be found who prescribes and treats patients on his own account. Massage is no new thing. It was described by a Chinese writer, Kong Fu, in or about the year 2,700 B.C., besides being mentioned by the Egyptians, Greeks and Romans. Its value in medicine was known to Hippocrates. It was not, however, until the early part of the nineteenth century that massage was placed upon a scientific basis by Ling, the founder of the Central Gymnastic Institute in Stockholm. As Miss Ellen Olsson has recently pointed out, the medical gymnast bears precisely the same relation to the physician as does the chemist. The nature of the curriculum through which masseurs of repute must have passed is a sufficient guarantee that they are competent to act intelligently and faithfully under the medical man's instructions. For the relief of many nervous and functional diseases a course of massage is often indispensable, while in many other affections it will go a long way towards completing the cure.
Aerophagy in Dyspepsia.
The swallowing of atmospheric air with each mouthful of food or drink occurs more frequently than is usually supposed. A very small quantity of air finds its way into the pharynx, no doubt, in every act of deglutition, but this is capable of being considerably increased by careless habits or in some varieties of nervous dyspepsia. No small proportion of the misery suffered by dyspepsics is owing to the simple accumulation in the stomach of swallowed air, though other gases are also formed in the gastro-intestinal tract itself as a result of certain fermentative changes. M. Morange, in a thesis upon the subject believes that many instances of so-called “flatulent dyspepsia” are due to the establishment of a vicious circle, the idea being taken hold of by the individual that the swallowing of air will, in some measure, relieve the pain and discomfort, whereas it only accentuates them.

"Aerophagy," as the process is termed, may thus be one of the manifestations of a neurotic tendency which is commonly met with in flatulent dyspeptics. Some forms of spasmodic hiccup, especially in hysterical subjects, are due to the swallowing of air, which Bouvieret maintains is produced by an actual neurosis of the pharynx. The more generally accepted view is, however, that dyspepsia is really the primary faulty condition, the aerophagy being superadded, more particularly in neuro-pathic individuals. The treatment consists in the administration of drugs which, like cocaine or menthol, depress any pharyngeal excitability, and in paying attention to the general health.

The Unrestrained Purchase of Morphia.
The ease with which patients can obtain fresh supplies of medicine containing morphia and its derivatives without any check on the part of the practitioner who prescribed the drug in the first instance, and in most cases without his knowledge at all, has frequently been the cause of such evils as the contraction of the morphia habit. A contemporary states that this practice has grown much in Paris of late, so that the authorities have been obliged to interfere by imposing fines upon the chemist who sells the drug. We are glad to think that, for the most part, chemists in this country are fully alive to their responsibilities in this matter, for it is not always so easy to obtain the drug as people seem to imagine. Nevertheless, a certain amount of abuse is still prevalent; more especially with regard to the indiscriminate repeating of prescriptions at the patients’ request without reference to the medical man. The evil can be stopped to a certain extent by crossing the prescription “Not to be repeated,” but there is, of course, nothing whatever to hinder copies being made of the document and their subsequent presentation to the pharmacist. It is not until it is made an illegal act to repeat a prescription of this sort without the written consent or re-signature of the prescriber that any real advance can be hoped for in this direction. The actual sale of morphia by itself in the form of tabloids is another matter, and it is to be regretted that facilities exist for the perfectly unrestrained purchase of the drug in that shape. Legislation can do a great deal, but it is only by the better education of the public as to the necessity of trusting to medical skill rather than their own inclinations or the recommendations of friends that true reform is possible.

Ear Grafting.
The latest medical sensation hailing from our lively and imaginative American cousins is the reported purchase of an ear by a physician acting on behalf of one of his patients. The latter, so the story runs, was a mining millionaire, who found the loss of his ear a bar to matrimony. In answer to an advertisement offering £1,000 for a living right ear to take the place of the missing member a crowd of applicants came forward. This array of candidates was ultimately reduced to two, whose ears most closely matched the one ear of the millionaire, and of whom the second was to act as a kind of reserve in the event of failure of the first, as the pugilists would say, “to come up to scratch.” It is stated that one of the selected men is a ruined German restaurant keeper and the other a bankrupt Wall Street broker. The names of both parties to this strange bargain are to be kept secret. Now, whether this story be sober truth or journalistic fable, it contains no outrage on possibility. The famous John Hunter long ago planted the spur of a cock in its comb, where the changeling spur thenceforth grew and flourished. That experiment laid the foundation of the triumphs of modern plastic surgery, whereby new noses, eyelids, lips and other features can be artificially replaced. Although we do not recall any case where an ear has been actually taken from one person and grafted upon another it is none the less to be regarded as quite a feasible operation. The grafting of living teeth under similar conditions has been frequently accomplished, and would most likely have become more popular were it not for the risk of accompanying transference of infection.

The Hickman Tragedy.
After a prolonged and careful investigation the Coroner’s jury engaged upon the inquiry into the death of Miss Hickman, the Lady Doctor, have arrived at the only conclusion possible under the circumstances of the case. The crucial evidence was that of Dr. Stevenson, the Home Office analyst, who obtained 1-10th grain of morphia from about eleven to twelve ounces of portions of stomach, intestines and kidneys, which were in a state of advanced decomposition. In his opinion a much larger quantity of morphia must have been taken, judging from the proportionate amount obtained from such a small portion of the viscera. The 6 oz. bottle and medicine glass found near the body showed no trace of poison. The scalpel was rusty but exhibited no traces of blood. The hypodermic syringe had not been cleaned after use, and showed traces of morphia sulphate in the barrel, but none in the hollow needle. There were twenty morphia tabloids, of which four (one grain) would form a minimum fatal dose. The jury returned a verdict of suicide while in a state of mental un-
soundness. The sympathy of the medical profession, as well as of the general public, will be freely given to the friends of the deceased, whose social and professional ties appear to have been of a particularly bright and attractive character.

Noise and Neurasthenia.
We live in a noisy world, and London is a very discordant orchestra of acoustic irritants. The cerebral disturbances wrought by auditory excitation are difficult to estimate, but no serious observer can doubt the important etiological relationship of noise and neurasthenia. Physicians may well sympathise with the efforts of the Council of the Betterment of London Association to secure a quieter Metropolis. There is perhaps much that is quaint and attractive in the puzzling cries of the cockney vendor, and the robust often experience a sense of exhilaration in the rush and roar of city life. But a constant dropping wears away the hardest stone, and to many the nerve-destroying street noises are almost insupportable. Commerce is not likely to be guided by committees of hygienists, and economic problems are not to be solved by attention to the likes and dislikes of nervous grumblers, but it is at least reasonable to expect that comfort and convenience be not altogether neglected, and we have no hesitation in saying that a more rigorous enforcement of by-laws respecting street-shouting, and a repaving of streets with material less noise producing, and a regulation of traction engines, milk carts and roystering motors would be profitable for the healthy and protecting for the weak and infirm. Neurasthenia widely prevails among all sorts and conditions of men. There is much in the modern mode of life provocative of this condition, but among causes the pernicious action of which might be greatly mitigated, noise must be accorded a prominent place.

Diagnosis of Pernicious Anaemia.
Though the clinical diagnosis of pernicious anaemia is not usually of extreme difficulty, yet most of our readers will be able to remember cases in which the diagnosis, even when made with due deliberation, proved by subsequent events to be erroneous. Though the physician always tries to exclude rigorously every other possible cause of the clinical condition of the patient, nevertheless he sometimes finds that he has overlooked some point of importance, and his diagnosis has to be amended. For instance, most of us have seen cases of secondary anaemia which simulated pernicious anaemia in its clinical features to such an extent as to render the differentiation by no means easy. We have seen a case of cancer of the stomach demonstrated to a class of students by a very sound teacher as one of pernicious anaemia, nor was the mistake discovered until a tumour became palpable. And, again, we have heard of "pernicious anaemia" subsisting on further observation into mere pregnancy. In his difficulty the physician has commonly had to resort to the pathologist, who, however, has been but of indifferent assistance. It is true he gives an interesting and exhaustive account of the fall of the blood and its constituent parts, but he has been loth to bind himself to an opinion. "Severe anaemia" is as much as he is usually willing to admit. If, however, the observations recently made by Dr. Hauston, of Belfast, a Research scholar of the British Medical Association, should be borne out by others, there are certain features which we may rely on in future to give us great help in distinguishing the disease. In a large number of cases (over 150) of severe anaemia examined by him, there were two features invariably associated in pernicious anaemia, and rarely in any other condition. These are increase of the blood-index and increase of megaloblasts. In a few cases of malignant disease the same features were present, but in a much smaller degree than was the average in pernicious anaemia. Of course, both these marks have been noticed before, but we have not elsewhere seen them so well supported by facts and figures.

PERSONAL.

DR. G. COLLINGWOOD ANDREWS, surgeon to the Hampstead Hospital, has been elected Mayor of Hampstead.

DR. S. HAMILTON, of Newport (Mon.), recently, on the occasion of his marriage, received a gratifying number of public presentations.

SIR HERMANN WEBER's lecture on "Means for the Prolongation of Life" will be delivered at the Royal College of Physicians of London on Thursday, December 3rd, at 5 p.m.

THE Lord Mayor's Dinner of the Society of Apothecaries, on the 10th inst., was presided over by the Master, Mr. Clarence Cooper, and proved a brilliant affair.

DR. T. G. MOORHEAD has been elected physician to the Royal City of Dublin Hospital in place of the late Sir George Duffy, and Dr. R. A. Stoney, surgeon to the hospital, in place of the late Mr. H. G. Croly.

THE fifth annual dinner of the Medical Graduates' College and Polyclinic will be held at the Trafalgar Restaurant, London, W., on Thursday, December 3rd, at 7.30 p.m., under the presidency of Mr. James Cantlie.

On November 5th, Mr. John Newport Langley, D.Sc., F.R.S., Fellow of Trinity College, was elected to fill the professorial chair in physiology in the University of Cambridge, vacant by the resignation of Sir Michael Foster, M.P.

On November 4th, the committee, medical staff, and other friends presented the honorary treasurer of the Royal Liverpool Infirmary, Mr. Ralph Brocklebank, with his portrait painted in oils in recognition of his long services to that institution.

THE Birthday Honours include the name of Mr. A. R. Manby, M.V.O., M.D.Durh., Surgeon Apothecary to the King and the Prince of Wales, who has received a well-deserved knighthood. A Companionship of the Order of St. Michael and St. George has been bestowed upon Captain T. H. M. Clarke, for services in Crete.

We regret to announce that Lord Roberts is suffering from an attack of pneumonia, the result of a chill contracted at Windsor, when he unveiled the memorial to Prince Christian Victor on November 4th last. For
The Crags research prize for the best piece of original work done during the current year by present or past students of the London School of Tropical Medicine has been awarded to Dr. Aldo Castellani for his researches into the etiology of sleeping sickness. Dr. Travers, who also competed for the prize, has been awarded honourable mention for his paper on beri-beri.

Professor Arthur Robinson, Hunterian Professor, is giving three lectures in the Theatre of the Royal College of Surgeons of England on November 16th, 18th, and 20th, at 5 p.m. His subject will be the early stages in the development of mammalian ova and the formation of the placenta in different groups of mammals.

The annual dinner of the British Gynaecological Society will take place at the Café Monico, Piccadilly Circus, London, W., on Friday, November 27th, at 7.30 p.m. Communications on the subject should be addressed to the honorary secretaries, Drs. J. H. Swanton, 40 Harley Street, Cavendish Square, W., and Dr. S. J. Aaron, 14 Stratford Place, W.

**Special Correspondence.**

[We do not hold ourselves responsible for the opinions of our correspondents.]

**SCOTLAND.**

**Edinburgh University and the Granting of Degrees in Veterinary Surgery.**—This was the principal piece of business at the recent statutory meeting of the General Council, the business committee of which had under consideration a draft ordinance instituting such degrees, and as a result of its deliberations the committee recommended that the council pass a resolution regretting that they could not approve the ordinance now submitted, and suggesting that the University Court should reconsider the ordinance. The main points elicited from the report and discussion thereon are as follows:—Admission to the veterinary profession is by one portal only, the qualification of the Royal College of Veterinary Surgeons, which holds local examinations, and recognises certain colleges as giving a qualifying course of instruction. A peculiar feature of the examinations is that until the present the only colleges qualifying for the next cannot be taken, and that a student who fails is disqualified from proceeding further unless he comes up again within a year. Certain funds for the endowment of chairs of comparative anatomy, bacteriology, and pathology at the veterinary colleges in Edinburgh will probably be forthcoming soon. The scheme of the ordinance is to institute bachelors' and doctors' degrees in veterinary medicine, modelled so far on the medical, but to a large extent dependent on the regulations made by the Senatus. The council take exception to the scheme on the ground that it runs counter to and fails below the Royal College regulations in important respects, and that the examination could not be regarded by that body as equivalent, even were the College to consent to modify its one portal system. They also criticise it adversely in various minor details. The report was discussed it was pointed out that the degrees would only be conferred on men who had obtained a diploma qualifying for admission to the register of veterinary surgeons, and that the qualification could not fall below the present standard. The object of the University was to enable veterinary surgeons to obtain the status which a university degree affords without having to go entirely outside their own line of work. On a division an amendment was carried welcoming the ordinance, and therefore rejecting the report of the business committee. It is stated that in addition to the endowments referred to, a considerable sum of money will be placed at the disposal of the University, for the purpose of founding a chair of comparative anatomy, should the University see their way to granting degrees in veterinary medicine.

**Ballachulish Quarries Dispute.**—This lock-out has now continued for ten months, and, though the company has made certain concessions, the men (most of whom have now obtained possession of the still intact lock-out list) have not obtained the reinstatement of Dr. Grant, and their right to select their own medical officer. The quarry men's committee recently made a series of proposals with the object of settling matters, among their demands being the withdrawal of the intercept against Dr. Grant, the appointment of the quarry medical attendant being left in the men's hands, and a cessation of deductions of wages for medical attendance without the men's consent. In reply, the company have practically conceded the points raised as to wages, and as to deductions for medical attendance, but have otherwise ignored the medical position. These terms the men have refused to accept, as they think that any settlement made should include Dr. Grant. So far as we know no objection has ever been publicly raised by the managers of the quarries to Dr. Grant, further than that they have the right to appoint who will as their own medical officer. Their legal right to take up this position has been endorsed by the Courts, but, merely because there is something about the business of some cupidity and deceit on the part of a company that has not been made public, the company might now, as an act of grace, concede what is fairly due to the men, and cannot be a material point, and end this unhappy dispute.

It should be stated that Dr. A. D. Kennedy gazetted as surgeon under the factory and workshops Act in succession to Dr. Grant, has received his appointment from the quarrymen, and is in full sympathy with them and his poorly-treat predecessor.

**Royal Hospital for Sick Children, Edinburgh.**—H. H. the Duchess of Argyll has graciously consented to open the new out-patient department of the hospital on December 8th.

**BELFAST.**

**The Typhoid Question.**—This question is still kept well before the public, and it is to be hoped will continue to be so until the authorities take vigorous action in the matter. One day last week one of the evening papers published a long interview on the question, with Dr. Williamson, a member of the Corporation, in which he freely criticised Professor Lorrain Smith's report. He thinks that this report throws too much blame on the water supply, and does not attach sufficient importance to the drainage system. In his anxiety to direct due attention to the drains, it is to be feared that Dr. Williamson makes out too good a case for the water supply. It may be as pure as the London supply, as he implies it is, but no medical man can defended the present state of affairs, when typhoid is practically endemic in the catchment area. The fact, if fact it be, that milk and butter are sold without let or hindrance from these same fever-stricken houses does not in the least reconcile us to drinking water polluted by their drainage. The interview will, however, do good by keeping the various points before the public, and Dr. Williamson has always been recognised as an independent member of the Corporation, and as a fearless critic of the often dark and devious ways of that body.

**The Consumption Question.**—The proposal of the Corporation to take a ten-acre field and fill it with shelters for consumptives like coops for pheasants, someone has said, is strongly condemned by Mr. Robert Brown, the honorary secretary of the Ulster Branch of the National Association for Prevention of Consumption. The difficulties which Mr. Brown finds are the conveying of the patients daily to and from the shelters in the trains, and the feeding of them when there. Whatever district of the city may be selected, the inhabitants of that district are quite sure
Correspondence.

To the Editor of The Medical Press and Circular.
Sir,—Until the occurrence of the Great Wyrely outbreak, the crime of cattle-maiming was unknown in England but common in Ireland, had always had some motive behind it, generally a desire for revenge on an unpopular farmer, and was an easy and comparatively safe way of obtaining a valuable animal for some offence against local public opinion, such as taking over the farm of an evicted tenant or giving certain information to the police. Here the crime, however atrocious, had some sort of raison d'etre. At Wyrely, however, the outbreaks have throughout been committed in an indiscriminate manner on the animals of various owners, and there appears to have been no motive whatever save the lust of cruelty and the desire to terrorise a whole district by threats conveyed in anonymous letters, as well as by the atrocities themselves. This, to my mind, points very clearly to the perpetrator labouring under some form of mental aberration, at any rate, mental instability. He may not be palpably insane; indeed, in all probability he is not; but he is almost surely the subject of hereditary neurosis—a semi-imbecile, a sufferer from moral insanity; the normal instance of a lunatic asylum who is now relapsing into lunacy again. Purposeless cruelty and destructive tendencies are well-recognised symptoms in imbeciles and in those morally insane, and these two mental conditions often merge imperceptibly one into the other. Imbecility has idiosyncrasy at one pole and moral insanity at the other.

It is such people who will commit acts of incendiarism, torture animals, or be guilty of homicide for the mere sake of the sensation or apprehension; and anonymous letters, to aggravate this terror, are a frequent weapon in their hands. These persons may show no symptom of mental deficiency; they may be capable of earning a living, and are usually cunning enough to take vast precautions in order to avoid their crimes being brought home to them. Careful examination may reveal in them, however, some of the stigmata of degeneration, such as asymmetrical or malformed ears, narrow and vauled palate, palsey, or semblance of some similar nature. If Edalji has been justly convicted, the question arises, Who are the authors of the outrages which have taken place during his incarceration in gaol? A possible explanation exists in the fact that the medical degenerates of whom I have been speaking are imitative to an immense degree, and we all know how usual it is for the perpetrator of a crime somewhat out of the common to be followed by imitators. Within the last few weeks there has been quite an epidemic of murder of young women by hobbledeys whom they have jilted. It may well have happened in this case at Wyrely that some person of weak intellect has been fascinated by the crimes and endeavours to imitate them. It affords, as I say, a possible explanation. A probable one is that Edalji is innocent, and that all the outrages have been committed by the same hand. That any gang exists for the purpose of committing these outrages is the anonymous letters suggest, and as the police seem to think, is to my mind out of the question. It was thought that Edalji declined bail in consequence of an understanding with his confederates that while he was in gaol other members of the gang should commit further outrages in order to prove his innocence. It is virtually impossible that sane men would band together and run such a risk for such a purpose, and equally so that enough moral lunatics could be found in one neighbourhood to form such a gang.

I quite agree with your editorial notice that any educated solicitor guilty of such senseless and purposeless crimes should on conviction be sent to a lunatic asylum rather than to a prison.

In conclusion, I would suggest that:
1. Minute search should be made into Edalji's family history for two or three generations back, with a view to tracing any insane relatives.
2. The police should search for and carefully watch the movements of any person in the neighbourhood who has to their knowledge ever been in an asylum, among whose relatives lunatics, drunkards, epileptics, criminals, and so forth. This should not be difficult in a sparsely-populated district like Wyrely, and much information as to local family histories of lunatics would be obtained from a perusal of the case-books of the county asylum, which the Medical Superintendent would doubtless be quite willing to place at the disposal of the police.

It is on the above lines that I think justice is most likely to be done.

I am, Sir, yours truly,
E. G. YOUNGER, M.D.
Mecklenburgh Square.

Medical Phonographer's Society.
To the Editor of The Medical Press and Circular.
Sir,—May we be permitted, as President and Officers of the Society of Medical Phonographers, to bring the continued existence of the Society and its usefulness, under the notice of any persons who have been, or students of medicine who make use of shorthand. Of late, the society has not come much under the notice of the profession, but its work continues. Its organ, the Phonographer, is Medical Record, affords the means of obtaining familiarity with medical shorthand, together with definite information on practical medical subjects. The society has also issued a series of small original works in literary shorthand with the most important medical terms and subjects, as well as an extensive vocabulary of convenient outlines, and guides to the use of shorthand both by the student and the prac
tioner. It has also held periodical examinations for students in order to encourage the acquisition and use of shorthand.

The invaluable aid which it can give in medical work, practical and theoretical, in case-taking and note-making, is realised by all who have used it, as it cannot be by others, and the importance of its acquisition before medical studies are commenced is so great that the society has endeavoured by every means to encourage this, but many practitioners who make constant use of shorthand have acquired it long after being engaged in practice. To all students and practitioners alike the society is open, and its members ready to give all possible help to those who are endeavouring to obtain the assistance of this time-saving art. The subscription to the society is very small, amounting only to 5s. per year for students and 7s. 6d. for practitioners.

The hon. secretary, Dr. Fletcher Beach, will be glad to give any further information and to receive applications for membership.

I am, Sir, yours truly,

DAVID FERRIER, President.
E. B. GRAY, Vice-Presidents.
W. R. GOWERS.
G. SIMS WOODHEAD.
NORMAN PORRITT, Treasurer.
FLETCHER BEACH, Secretary.

Winchester House, Kingston Hill, Surrey.
November 13th, 1903.

OBITUARY.

SIR CHARLES NICHOLSON, BART.

We regret to announce the death of Sir Charles Nicholson, Bart., at Totteridge, on November 8th. He was born on November 23rd, 1808, took the M.D. degree of Edinburgh in 1833, and in the following year emigrated to Australia. He started in practice in Sydney, and was elected a member of the first Legislative Council of New South Wales in 1844, and was three times chosen Speaker of that body between 1845 and 1856. He was the first Chancellor of the University of Sydney, an office which he held from 1854 to 1860, and returned to England some ten years later. His death closes a remarkably varied and successful career.

DR. G. H. AYRES.

The death is announced of Dr. George Henry Ayres, which occurred at his residence, 58 West Derby Road, Liverpool, on Thursday. He was a well-known practitioner, and had a most successful career.

MR. P. B. MASON.

The announcement of the death of Mr. Philip Brookes Mason, of Burton-upon-Trent, will be received with general regret. He commenced his medical education at Glasgow in 1858, and afterwards entered University College, London. After a brilliant career as a student, he became M.R.C.S. and L.S.A. of London. From 1870 he was surgeon to the Burton-on-Trent Infirmary, and it is recorded that he was the first surgeon in the neighbourhood to perform ovario-
tomy. He was also surgeon to the Burton-on-Trent Dispensary and to the Post Office. Mr. Mason was a great naturalist and had a magnificent collection of beetles.

LITERATURE.

Nov. 18, 1903.

UNDERWOOD'S COMPARATIVE ODONTOLOGY. (a)

Mr. Underwood prefaces his latest work with the remark that its immediate object is to render the study of comparative odontology easier and more attractive to the student. We are of opinion that he has succeeded in both these endeavours, although comparative odontology needs little to enhance its natural attractions. Comparative dental anatomy at once the most interesting and the most fascinating of all the purely scientific subjects of the dental student's curriculum, and to him, we take it, this book is in the main addressed. Experience shows, moreover, that it is a subject in which the average candidate for examination is almost invariably well grounded. This is, no doubt, due to the thoroughness of the teaching in the various schools, and to the excellent textbook which we possess in Mr. Tonn's work, but it also tends to give the student interest which is taken in this subject by the majority of students. We have perused Mr. Underwood's book with pleasure. The arrangement of the subject-matter is distinctly good, the language is lucid, the illustrations, which are by Mrs. Underwood, are well drawn and clearly reproduced; there are few, if any, errata, and the last two chapters, entitled respectively "The effect of environment upon animals" and "The chain of life," will repay careful perusal. Finally, we welcome as a most useful auxiliary to the better understanding of those portions of the text dealing with paleontology the table of stratified rocks on page 27. This gives at a glance the sequence and significance of those geological periods with which all students of comparative dental anatomy make early acquaintance, and the meaning of which, we fear, is to many of them far from clear. Mr. Underwood's manual will prove a valuable addition to the dental student's library, and it ought to find many readers among scientific students of every class when once its merits have become known to them.

MANKIND IN THE MAKING. (b)

Mr. H. G. Wells has gained wide renown by his scientifically directed romances and much popularity by his attractive novels; but judging by his recent plant sociological essay, "Anticipations," and his latest production, it is as a serious writer and deep thinker concerning matters which go to the making of men that he deserves to win lasting distinction. And Mr. Wells has certainly come to his own. The present volume is a valuable contribution to questions of vital importance and will be of permanent interest. It is an attempt to deal with social and political questions in a new way and from a new starting-point. A comprehensive view is taken, and the author with firm grasp, scientific in its precision and yet sympathetic in its direction, seeks to group human affairs in orderly array as parts of one universal evolving scheme. The necessity there are errors of commission and defects of omission, but taken as a whole the work is not only remarkable in its design, but admirable in its execution. It is a volume which should be read and studied by every thoughtful Englishman, and particularly commend it to the attention of members of the medical profession.

There is originality of thought, freshness of expression, fertility in illustration, and an audacity in attacking long-established customs, yet, withal, a scientific optimism and something of a seer-like intuitiveness which makes this work particularly

(b) "Mankind in the Making." By H. G. Wells. London: Chapman and Hall, Ltd. 1904. Price 2s. 6d.
refreshing. Every page is laden with suggestive thought and no paragraph is without interest.

The work attempted is not so much special and technical as a work of reconciliation, the suggestion of broad points of view to meet the aims and interests of divergent specialists. It is of the utmost importance that the medical man may see the many viewpoints and arrangements which are possible in connexion with the fertilisation of the ovum. Dr. Bandler talks of the ovum as a theme, and the ovum is the subject of the ovum. The subject is the ovum, and the ovum is the subject of the ovum.

In his chapters on the cultivation of the imagination, the expression of the desire for self-assertion and constructive energy, the individual is the subject of the individual. The book deals with the individual as a whole, and in this respect it is in the right spirit.

We are pleased to find that Dr. Bandler has published in book form a series of articles which appeared under his name in the New York Journal of Obstetrics and Gynecology. The book is a well-known work in that journal, and the present book represents one of many contributions. The book contains much that is very new, in fact, much that is as yet far from being generally received, and will well repay perusal. The author inclines strongly to the belief that the placenta possesses glandular functions, and that its secretion is of great importance. He brings forward several personal views concerning the formation of villi and the blood-forming action of the trophoblast, and, as he confesses himself, a full realisation of the criticism has left him to be proved correct or otherwise. His views on the causation of menstruation, labour, and eclampsia are decided striking. Ovarian secretion, he considers, exerts great trophic influence upon the uterus, and is responsible for the occurrence of menstrual phenomena. When, however, ovulation and the development of the ovum take place, the ovum and its enzymes nullify the menstrual stimulation of the ovarian secretion. However, at the end of nine months the ovarian secretion is sufficient in amount to overcome the neutralising action of these enzymes, and labour occurs. If shortly before, during, or after labour, there is an overwhelming superiority of ovarian secretion over the placental, the constitutional involvement known as eclampsia results. Truly no one can say that Dr. Bandler's book does not merit the beaten tracks of obstetrical beliefs.

**MEDICAL EXAMINATIONS FOR LIFE ASSURANCE.** (a)

This concise little handbook for medical men called upon to act as advisers to assurance offices has for long been deservedly popular. Although by no means exhaustive, and even in some respects not sufficiently explicit, it admirably meets the requirements of the general practitioner who in the course of ordinary practice may be required to examine applicants for life assurance. It is not intended for the assurance expert or statistical specialist, but well serves its purpose as a clear and fair guide to the inexperienced. The present, third edition, has been considerably enlarged, thoroughly revised, and, we think we may safely say, much improved. All phases of the subject are presented, but certain portions might well have been extended with advantage. The young medical practitioner who would do well in his own interests to study the section on the selection of an office and much assistance may be expected from the conveniently arranged table of assurance offices. The frontispiece consists of a coloured map, which conveniently indicates at a glance the usual rates adopted for foreign residence. Dr. de Haviland Hall's little manual has been well designed and admirably executed; we have no hesitation in recommending it to the consideration of practitioners whose duty may require them to undertake the examination of cases for life assurance purposes.

**Medical News.**

**Death from "Potash" Pellets.**

An inquiry was held at the Railway Hotel, Snaith, last week, into the death of a little boy, four years of age, named Francis Barradough. Decrees, who had been given potash pellets for a relaxed throat, unknown to his parents, took about twenty from the box and ate them. The doctor who administered an emetic to the child, said twelve pellets would prove a fatal dose for a young child. A verdict was returned of "Accidental death." It may be presumed the "potash" pellets were chlorate of potash. The case, is, accepting that version, probably unique.

**Coaching by Correspondence.**

At Buxton, Dr. William T. Hannah, a well-known medical man of Buxton, brought an action against Mr. E. Gooch, Principal of the Medical Diploma Correspondence Institute, London, to recover two guineas.

paid in advance for lectures by correspondence on certain medical subjects. The doctor saw an advertisement in a medical journal as the result of which he corresponded with the defendant, with reference to a course of instruction by correspondence in connection with a diploma as M.R.C.P., London. A course of twenty-five communications was to be given for eight guineas, and two guineas was sent for one quarter. No instruction had, however, been given, and the claim was for repayment. There being no appearance for the defence, judgment was given for the amount claimed with costs.

Central Midwives Board.

At a meeting of the Central Midwives Board, held on October 29th, Dr. F. H. Champneys in the chair, the following business was transacted:—(1) A letter was read informing the Board that a person had visited a nursing institution and had endeavoured to collect the fees for certification. The Board desire it to be known that the secretary alone is authorised to receive the fees. (2) A letter was read from the Colonial Nursing Association directing the attention of the Board to the case of the midwives now working abroad, sent out by the Association. As most of them were in distant parts of the world they would not be practically possible for them to forward their certificates to the secretary for verification. Under the special circumstances of these cases the Board resolved to adopt the procedure prescribed by the rules in the case of long-distance certificates. (3) The secretary was instructed to add the Rural Midwives Association, 47 Victoria Street, S.W., to the list of bodies to whom applicants for training should be referred. (4) The Board resolved to receive the certificates of the following bodies as approved qualifications under Section 2 of the Midwives Act, 1902: (a) Queen Charlotte’s Lying-in Hospital, (b) Manchester Southern and Maternity Hospital, (c) Liverpool Ladies Charity and Maternity Hospital, (d) British Lying-in Hospital, (e) Glasgow Maternity Hospital, (f) St. Mary’s Hospital, Manchester. (5) The consideration of other applications approved by the Board was for the present deferred. (6) Draft rules of procedure on the proposed removal of a midwife’s name from the Roll, or cancelling of her certificate, were considered, amended, and ordered to be forwarded to the Privy Council for approval. (7) After application for certificates, the names of 126 women were passed under Section 2 of the Act, and ordered for entry on the Roll. Of this total 74 claimed as holding the certificate of the Obstetrical Society of London, 3 that of the Rotunda Hospital, Dublin, and 49 were admitted as having been in bona-fide practice for one year prior to July 31st, 1902. (8) A design of certificate on parchment was approved and ordered to be printed. (9) A form of certificate of identity, as prepared by the secretary, was adopted and ordered to be printed and issued as the other official forms of the Board. (10) The tender of Messrs. Spottswood & Co., Ltd., 54, Gracechurch Street, E.C., for printing was accepted. The Register can be obtained from Messrs. Spottswood as above quoted price is. (11) The Secretary reported that as the Privy Council had raised no objection to the Board issuing their “Suggestions to County and Borough Councils” on their own responsibility, he had sent copies to all those Councils—about fifty in number, who had applied for them.

London School of Tropical Medicine.

The Crapps’ research prize, for the best piece of original work done during the current year by present or past students of the School, has been awarded to Dr. Aldo Castellani for his researches into the etiology of sleeping sickness. It will be remembered that Dr. Castellani (of the University of Milan) had isolated a peculiar substance from the blood of persons suffering from sleeping sickness, and was the first to point out the association of trypanosomes with this disease, having demonstrated their frequent presence in the cerebro-spinal fluid as well as in the blood. Dr. Travassos, who also competed for the prize, has been awarded honourable mention for his paper on beri-beri.

Dublin University Biological Association.

The opening meeting of this Association will be held on Thursday next in the Front Hall, Trinity College, at 8.15 p.m., when the President, Mr. R. C. B. Maunsell, F.R.C.S., will deliver an address on “Surgical Anatomy.” The Vice-President, Mr. W. S. Paterson, F.R.C.S., on the address will be Mr. A. W. Mayo Robson, F.R.C.S., Sir C. B. Ball, F.R.C.S., Mr. E. H. Taylor, F.R.C.S., and Mr. J. Lumsden, M.D.

Royal College of Physicians of Ireland.

At the stated meeting of the President and Fellows of the Royal College of Physicians of Ireland, held on the 13th inst., the following were admitted to the grade of Licentiates in Medicine of the College:—Mrs. Agnes Forbes Savill, M.D.; Thomas Gillman Moorhead, M.D.

St. Andrews Graduates’ Association.

At a general meeting of the association held on November 5th, it was unanimously agreed that the Association, having fulfilled the objects for which it was instituted, be dissolved, and that the balance standing to its credit be equally divided between the British Medical Benevolent Fund and the Royal Medical Benevolent Fund, Epsom.

Cancerini.

From the Vienna correspondent of the Lancet we quote the following interesting account of a professional imbroglio:—Some years ago Professor Albert Adamkiewicz, of Cracow, in Austrian Poland, read a paper at the International Congress of Physicians in Vienna on the use of curare against carcinoma. This remedy, to which he gave the name of cancrium, was a solution of choline, citric acid, and phenol. The most eminent physicians as surgeons, however, such as Bûrolh, Albert, and Kashey, agreed that this method of treatment had nothing to recommend it, and Professor Adamkiewicz has therefore sought some other way of inducing the professors to make use of cancrium. In the middle of October the chief surgeons of the public hospitals belonging to the State were surprised by receiving an order from the Home Secretary to make trials of the cancrium of Professor Adamkiewicz. This remarkable and unprecedented order has naturally aroused much indignation in medical circles. Professor Adamkiewicz also called the newspapers to his aid, publishing most encouraging results of the treatment of cancer by means of cancrium, but Dr. Husche, of Rostock, has stated that one of the patients whom Professor Adamkiewicz and Dr. Katscher claimed to have cured really died from cancer of the stomach a short time after treatment with cancrium.

Society of Apothecaries of London.

The Lord Mayor’s Day dinner of the Society of Apothecaries was held at the Society’s hall in Blackfriars, London, on November 10th, the Master of the Society, Mr. Clarence Cooper, being in the chair. The dinner was accompanied by a toast to Sir Albert B. Day and Mr. Sir J. H. Jeffcoat. Among the guests were Sir W. S. Church, President of the Royal College of Physicians of London, Mr. J. Tweedy, President of the Royal College of Surgeons of England, Mr. A. Gibbs, M.P., Sir Joseph Fayrer, Professor A. Macadyen, Sir Hugh Beevor, Sir William Wilson, Sir Trevor Lawrence, Dr. F. T. Roberts, Mr. S. R. Atkins, President of the Chemical Pharmaceutical Society, Mr. S. S. Crowell, Mr. Shirlow F. Murphy, Dr. Dawson Williams, Mr. W. Arbuthnot Lane, Mr. W. A. Frost, Mr. Andrew Clark, and Mr. G. H. Makins. Sir William S. Church, as a visitor, said that there was a close connection between the society of Apothecaries and St. Bartholomew’s Hospital, and for more than two centuries there had been at St. Bartholomew’s a resident apothecary, the last being Mr. Frederic Wheeler, to whom he (Sir William Church) had succeeded, and who had bequeathed in his will a sum for the benefit of the apothecary of St. Bartholomew’s Hospital. Dr. Church said that all must respect the useful work done by that Society in the interest of the medical profession. The Society of Apothecaries had fulfilled an important function in the education of physicians and surgeons, and it was his opinion the medical student was in danger of being over-educated and he would rejoice to see that Society take a larger share in the future in medical education and qualification. The subject was an economical one.
as well as educational, because the increasing cost of medical education had reached such a degree that a man had to consider whether it was worth while paying for the costly and elaborate training required for the University of London with no further recompense at the end than such as was to be gained in remote country districts. Mr. Cooper, in acknowledging the toast, expressed the hope that the Medical Officer of Health Society had lately been affording opportunities for the progress of medical science.

Dublin Death Rate.

The deaths registered during the week ending Saturday, November 7th, 1903, in the Dublin registration area represent an annual death-rate of 22.8 in every 1,000 of the population. Tuberculous disease caused 36 deaths; diseases of the respiratory system caused 36 deaths; diseases of the nervous system caused 20 deaths; and diseases of the heart and blood vessels caused 23 deaths; 45 infants died during the week, of whom 32 were under one year old. In 9 instances the cause of death was uncertain, there having been no medical attendant during the last illness. In the city the death-rate was in the Clarence Street North district, 35.8 per 1,000; in the Lisburn Street district, 26.0 per 1,000; in the South Earl Street district, 29.0 per 1,000; and in the Castle Street district, 39.9 per 1,000.

The Royal Waterloo Hospital for Children and Women.

This hospital, which was founded in the reign of George III., is now in course of reconstruction, reorganisation, and enlargement. The Board are in hopes of establishing cots, and, if possible, entire wards, to be supported by various public bodies. Owing to the fact that the new Union Jack Club will shortly be erected in the immediate vicinity, they hope to establish a military ward, with the assistance of the various London corps. The name and regimental crest of each cot shall be fixed at the head of each cot and devoted to the sick children and wives of the rank and file; 600 shillings, or 30 guineas annually, will support a cot, or the capital sum of 1,000 guineas. Already one individual has generously promised to endow a cot, on condition that five others will do the same.

Royal City of Dublin Hospital.

At a meeting of the Board of the above hospital, held on Friday last, Mr. T. Gillman Moorhead was elected a physician to the hospital, and Dr. R. A. Stoney, a surgeon, in the place of the late Sir George Duffe, and the late Mr. Henry Gray Croly respectively. Mr. Moorhead has held the post of assistant physician to Sir John D'Arcy's Own's Hospital for some years, and had a most distinguished University course, gaining amongst other distinctions the Medical Travelling Prize. Dr. Stoney has not previously held a hospital appointment, but he has also had a most distinguished University career. He has been for some time senior demonstrator in the anatomical department of the School of Physics, Trinity College, and during the interregnum between the departure of Professor Cunningham and the taking up of office by Dr. Dixon discharged with success, in conjunction with Mr. Moorhead, the duties of the management of the anatomical department. The staff of the City of Dublin Hospital may be congratulated on the appointment of these gentlemen.

Typhoid Fever in Southend.

Dr. Nash, the medical officer of Southend, has reported that out of twenty-three cases of typhoid fever reported in the borough during October, there was a definite history of the eating of shellfish in eleven cases. Of the remaining cases, one proved to be not typhoid, while two had partaken of watercress. Dr. Nash pertinently remarked: "Thus again in October, in about 80 per cent. of the cases notified, after discounting as far as possible all other known factors, the evidence points strongly to shell-fish from sewage-polluted sources."

New Medical Officer of Health

The Sunderland County Borough Council voted on three names for the position of Medical Officer of Health for the borough. The salary is £500 per annum for the borough and £420 per annum for the port. There were thirty-six applications received, and the Health Committee selected from this number Dr. A. E. Brindley, Medical Officer of Health, Newcastle; Dr. H. Renney, Deputy Medical Officer of Health, Sunderland; Dr. C. V. Dingle, Medical Officer of Health, Middlesbrough. Of these three the Health Committee recommended the appointment of Dr. Brindley. The voting resulted as follows:—Renney, 12; Brindley, 13; Dingle, 7. Dr. Renney was declared elected. Dr. H. Renney, formerly Deputy Medical Officer of Health for Sunderland (Port and Borough) has been appointed Medical Officer of Health for that town.

The Treatment of Consumption.

At a conference at Stafford on November 10th, between representatives of the County Council and local authorities, an offer by Colonel J. H. Wilkinson, of Ashfurchild, Hall, Sutton Coldfield, to provide a site at Berry Hill, Lichfield, valued at £2,400, for a sanatorium for consumptives, was considered, and a resolution declaring the desirability of such a sanatorium was carried.

A Good Riddance.

The medical profession in London are well rid of one pest for the next three and a half years. A well-known thief has just been convicted of several thefts from medical men. His plan was to watch the doctor off on his rounds, then go his house, and on being told he was out, to ask to leave a note. He had covered a wide area of the Metropolis in his operations, including some of the most fashionable quarters.

Death of Radica.

The following interesting piece of news comes from Paris.—Radica, the survivor of the Hindoo twins, who were separated by Dr. Doyen, died in hospital on Saturday from the results of the consumption which had attacked both her and her sister.

A Most Enjoyable and Successful Entertainment was given to the in-patients of the Cancer Hospital, Fulham Road, S.W., on Thursday evening last, by the Social Dramatic Company, under the management of Mr. Reginald H. Lindley. The farcical comedy, entitled "The Strange Adventures of Miss Bibb," by the late R. Buchanan and Charles Marlow, was acted. A hearty vote of thanks, proposed by the Secretary, Mr. F. W. Howell, was accorded with acclamation. During the interval Mrs. Grant very kindly played some pianoforte selections.

Rats in the Port of London.

Dr. Williams, the Medical Officer of Health for the Port of London reports the destruction of 6,000 rats between September 27th and October 24th, bringing up the total death-roll to 250,000.

Conjoint Examinations in Ireland.

The following candidates have passed the Final Examination by the Royal College of Physicians and the Royal College of Surgeons:—Honours.—M. J. Ryan. Pass.—E. B. Bird, J. Carney, A. H. R. Duncan, G. H. Enright, James Hayes, D. F. Hegarty, P. J. Irwin, L. C. E. Murphy, J. J. M'Connell, P. J. O'Farrell, C. F. P. Flunkett, J. J. Ryan, P. Sampson, Geo. G. M. L. Rabateau. These gentlemen will be admitted to the Licenses—if of full age—on Thursday (Surgeons) and Friday (Physicians).

The undermentioned candidates have passed the Public Health Examination:—

NOTICES TO CORRESPONDENTS.

Appointments.

Duncan, W., F.R.C.S., L.R.C.P. & L.R.C.S. Edin., House Surgeon to Nottingham Children's Hospital.

Greenwood, A., M.D., D. Phil., D. P. H., Medical Officer of Health of Blackburn, Medical Officer to the Blackburn Education Authority.

Hare, W., D.S.O., M.R.C.S., L.S.A. (Lon.), M.B. (Edin.), Lecturer on First Aid and Nursing, London School Board, and Clinical Assistant to the Evelina Hospital for Children.

Parker, E. D., L.R.C.P. Lond., M.B., F.R.C.S., House Physician to the Evelina Hospital for Sick Children.

Samuel, Henry T., L.R.C.P. Lond., M.R.C.S., Assistant Physician to the Cardiac Infirmary.

Turner, J. R., L.R.C.P. Lond., Assistant Surgeon to the Evelina Hospital for Sick Children.

Vacciniae.

Bath Hospital.—Two Resident House Physicians. Apartments for complete board, and washing being required. A half-year's salary at the rate of £25 each, and £24 per annum will be paid. Applications to the Treasurer, Bridewell Hospital, New Bridge Street, E.C. 4 (advt).

Brighton, Hove, and Sussex Thoracic and Ear Hospital, Church St., Queen's Road, Brighton.—Non-Resident Surgeon, £350 per annum. Applications to the Committee of Management.

Liverpool Stanley Hospital.—Certifying Surgeon, Salary £300 per annum, with board, residence, and washing. Applications to the Chairman of the Medical Board.

Northwich Lock Hospital.—House Surgeon. Salary £200 per annum, with board, lodging, and washing. Applications to the Secretary, Macclesfield.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £150 per annum. Applications (to the Honorary Secretary), Joseph Carr, 44 Mosley Street, Newcastle-on-Tyne.

Sheffield Children's Hospital.—Lady House Surgeon. Salary £175 per annum. Applications to Mr. Frederick Gill, Secretary, 14 Norfolk Row, Sheffield.

St. Mary's Hospital, Midlothian, Edinburgh, W.—Lecturer on Physiology, £400 per annum. Applications to H. A. Cayley, M.D., F.B.C.S., Dean.

The Royal Infirmary, Sheffield.—Maiton, Salary £200 per annum, with board and washing. Applications to the Secretary.

Wolverhampton Union.—Assistant Medical Officer. Salary £200 per annum, together with apartments, residence, and washing. Applications to Frank Harrison, Clerk to the Guardians.

Wrexham Infirmary.—Resident House Surgeon, Salary £250 per annum, with board, lodging, and washing. Applications to J. Bagnall Bury, Secretary, 9 Temple Row, Wrexham, North Wales.

BIRTH.

Masor.—On Nov. 10th, at Cumberland House, Somerset Road, South Kensington, the wife of Harry T. Masor, M.R.C.S., L.R.C.P., of a daughter (stillborn).

Marriage.

Chapel.—Garwood.—On Nov. 12th, at the Parish Church, Bowden, George Pester Chappell, M.D., of Tottenham, son of the late Canon Chappell, Camborne, Cornwall, to Mary Emily, only daughter of Harry T. Masor, M.D., of Bowden, Cheshire.

Baths.

Alexandra.—On Nov. 3rd, at Morden, Middlesex, Ellis Harriet, widow of the late Alexander Charles Archibald Alexander, B.A., Can., of Predominance, Major, of Cradock, to Major John D. Bowden, F.R.C.P.

Nicholas.—On Nov. 8th, at the Orangery, Totteridge, Sir Charles Nicholas, Bart., M.D., C.B., D.C.L., of Cradock and Edin, aged 49.
Original Communications.

SOME QUESTIONS IN SEASIDE CLIMATOLOGY. (a)
By ALFRED F. STREET, M.A., M.D., D.P.H., Westgate-on-Sea.

PART I.

My remarks will concern certain questions which have long interested me with regard to the air of Westgate-on-Sea, where I have the good fortune to live. That locality, Dr. Ord says, is "singularly pure and invigorating," and Dr. Burney Yeo tells us its air has "important tonic properties," while Dr. Ewart writes that it has a soil drier than almost any other in England, that it is the last to be visited by the storms which come to us from the Atlantic; that owing to the absorbent qualities of its soil its land wind is more than usually free from moisture; that it enjoys almost the full advantage of the warmth of the Gulf Stream; and that his only indictment against it is that it is "hyperventilated," for it is on record that the number of calm days in the year is only thirty-eight.

That close observer, the late Sir James Paget, said to me nearly twenty years ago that his experience was that many scrofulous patients would get well there when they would not elsewhere. He frankly admitted that he could not say what special property the air had, but as to its effects he entertained no doubt.

Can we, in the light of the fuller knowledge of to-day, point to facts which may to some extent explain the essential causes of differences of climate such as do not find full explanation by the barometer, the thermometer, and other ordinary meteorological instruments? For it has been very truly said that just as no two faces are alike so there are no two places having quite the same climate.

The factors of climate are said to be reducible to—
1. Distance from the equator.
2. Distance from the sea.
3. Height above the sea.
4. Direction of most prevalent winds.

But this is only a very partial statement of the truth; for instance, it takes no cognisance of so potent a factor as the Gulf Stream, to which we in these islands are indebted for the advantage that though London has the latitude of Labrador it has a far higher mean winter temperature.

Nor does the statement that "weather spells climate" carry the whole truth, for there are many other factors in climate, at any rate in local climate, which after all is what chiefly concerns our patients.

Besides such local influences as the Gulf Stream there are the configuration and inclination of the land, the character as to porosity or drainage of the soil, the presence or absence of vegetation, of cultivation, of plantations or of forests, the degree of protection afforded by trees, by mountain ranges, or merely by higher ground in the vicinity, the density of population, the neighbourhood of manufactories and their nature and so on. It would be more true to say that climate depends upon soil, air, temperature, moisture, solar radiation in its many forms, and possibly on electrical and other less known conditions.

Can we make any notable advance towards that clearer insight which enables us to replace empirical by rational knowledge?

In considering the claims of any locality with reference to the cure of any disease the first question which presents itself is: To what extent does that particular malady prevail among those born and bred in the locality? If we take scrofula as an example it must be conceded that the northeast corner of Kent, for instance, comes out exceedingly well. Those who practise there find very little home-grown tuberculosis, and imported cases commonly do well.

In the face of the prolonged experience of many careful observers extending over many years, it would surely be unreasonable to deny the claims of various localities to be credited with various aures, and the further question arises: To what factor or combination of factors does a particular locality owe its influence? We all know that in the case of a spa the popular answer is "To the waters," and in the case of most seaside places "To the air."

When a visitor comes to the seaside it matters not whether he feels better or worse. The cause so far as he is concerned is "The air." Perhaps he calls it "The strong air." He does not know what he means by the epithet "strong," but it has the advantage of being capable of conveying either praise or blame. Indeed, one constantly finds it considered capable of producing diametrically opposite effects in different people. One has diarrhoea. The cause is not unripe plums, but "the strong air." Another is constipated; he forgets all about his personal negligences, and again it is "the strong air," and so on.

We cannot credit the air alone with antituberculous virtues. We must give due weight to sunshine and dryness of soil and many other climatic factors. Relative humidity is a thorny subject.

(a) Presidential Address delivered before the British Biometrical and Climatological Society, on Friday, October 20th, 1903.

where the retreating tide exposed many acres of sewage-polluted mud I was asked to believe that the mud generated ozone.

The so-called ozone of pine forests has been shown to be camphoric acid, and not ozone at all.

In connection with the claims of ozone there are those of peroxide of hydrogen to be considered, but we know scarcely more than that chemists have been aware of its existence in atmospheric air since it was discovered by Schönbein in 1840. He found that it was formed together with ozone during all the slow oxidation processes in course of which the latter is formed and also during its electrical production. It has not been found by Clermont in most unexpected places—in vines, in lettuce, and even in tobacco-juice.

There are special chemical reasons for believing that it is present in the atmosphere, for Fenton has shown that tartaric acid in presence of iron gives, when exposed to air and sunshine, the characteristic odour of ozone. He finds that sunshine and air may in this reaction be replaced by peroxide of hydrogen, but not by ozone nor by nitrous acid, so that he very plausibly argues that peroxide of hydrogen is formed by the action of the sun on the air. But books on climatology disregard it, and no one seems to have discovered himself in connection with whether climatological or physiological, though Meissner, in 1865, claimed to have detected its constant presence in atmospheric air, and Struve found it in water and in snow. There is not much probability that it will succeed to the reputation which ozone does not deserve, though such influence as it has is not good, but if it exists, it is always ready to hand on its extra atom of oxygen.

It has been supposed that the chloride of sodium diffused by spray in seaside air has a tonic effect, but it seems hardly reasonable to think that a very minute quantity of a chemically inert body should have important effects on the body which is possessed of such an exquisitely fine instrument as the eye, and iodine and bromine have also been brought forward, but in what compounds and in what quantities we are not told, and considering the usual medicinal doses of their compounds the quantities possibly present in the air must be quite unimportant. A consideration of what is known of nations he has never married and no one shows them to be extraordinarily inert, for they form no known compound, and therefore have no polarity. One is inclined to wonder if there is not here an exception to what is said to be the only undisputed maxim in philosophy, namely, "Natura nihil agit frustra," but in the hands of Professors Léeing and Dewar the diatomic molecule has shown itself like krypton at any rate, the maxim still holds good, for krypton is probably responsible for one of the green rays of the aurora borealis.

The same observers tell us that in the spectrum of the gas which separates from atmospheric air solidified by liquid hydrogen, and which has so far proved to be incondensible, there are a vast number of rays, red which have been shown to be the infra-red ray of krypton, at any rate, the maxim still holds good, for krypton is probably responsible for one of the green rays of the aurora borealis.

The abdomen is distended by a large tumour, which rises to within two inches of the ensiform cartilage; the percussion note is normal in the flanks and epigastrium, but it is dull over the whole tumour which is hard and tense on palpation, but not uniformly so, and at its summit there is a hard rounded prominence; below this and to the left there is a shallow depression, and still further downwards and to the left there is another markedly hard rounded prominence. Fluctuation is not evident, but when an assistant pressed with the edge of the hand in the mid-line, a sharp pain and the tumour gave an impulse against the finger on the opposite side. There is half an inch of difference in the measurements from umbilicus to the anterior superior iliac spines, the right being greater. No movements have been felt by the patient; no fetal heart sounds have been de-

MULTILOCULAR OVARIAN CYST OF SIX MONTHS' GROWTH, WITH SOLID CONTENTS WEIGHING 22+ POUNDS.

By F. A. PURCELL, M.D., (a)
Surgeon to the Cancer Hospital.

The specimen was taken from E.F., a married woman without any children, aged 32, who was admitted to the Cancer Hospital, September 22, 1903.

History.—Complaining of a tumour in her abdomen, causing severe throbbing pain. The tumour was first noticed at the end of last May, when it reached just above the symphysis pubis. It has been growing steadily since. The patient had been married eighteen months; she had a menstrual cycle of twenty-eight days, and a period of five days; much blood was lost at times of menstruation. She was regular up to the end of September, 1902, and then fourteen weeks elapsed before the menses returned. Immediately after this there was a "flooding" lasting for six or seven weeks, the discharge being thin, slightly blood-stained, and extremely offensive, but accompanied by any other symptoms to cause her alarm; she did not then seek medical advice nor take to her bed. The flooding ceased suddenly. Since then she had often had a loss of blood in addition to that of menstruation, and since January 1st, 1903, she has seldom gone more than a week at a time without haemorrhage. She has never passed any-thing larger or more remarkable than large clots. She is rather troubled with her micturition; sometimes she passes none for a whole day, but, as a rule, she has a frequent desire to make water; there is nothing about the urine to call for note.

Her bowels were regular; according to her own story, and that of her husband, she has lost flesh to a marked degree, but is not yet particularly emaciated.

Examination.—The abdomen is distended by a large tumour, which rises to within two inches of the ensiform cartilage; the percussion note is normal in the flanks and epigastrium, but it is dull over the whole tumour which is hard and tense on palpation, but not uniformly so, and at its summit there is a hard rounded prominence; below this and to the left there is a shallow depression, and still further downwards and to the left there is another markedly hard rounded prominence. Fluctuation is not evident, but when an assistant pressed with the edge of the hand in the mid-line, a sharp pain and the tumour gave an impulse against the finger on the opposite side. There is half an inch of difference in the measurements from umbilicus to the anterior superior iliac spines, the right being greater. No movements have been felt by the patient; no fetal heart sounds have been de-
tected. Over an area of two inches in the line between the right anterior superior iliac spine and the umbilicus a venous hum is heard (the right ovarian vessels); the umbilicus is everted.

Vaginal examination reveals a soft edematous cervix, drawn upwards; and filling the pelvis there was a large tense mass, not to be differentiated from the uterus; the uterine sound was not passed.

The breasts, although there were dark areole round the nipples, were shrunk and small, and no milk could be expressed.

The patient was examined by the members of the staff of the hospital. Opinions differed and suggestions were made to postpone operation with the view of further developments; the majority, however, ruled for intervention.

Operation.—She was duly prepared for operation, and on September 30th, 1903, she was anaesthetised and brought to the theatre. A four-inch incision was made in the middle line below the umbilicus; on exposing the tumour the ovarian vein and tube showed the engorged vein crossing across the base of the ovary to the right. On inserting the examining hand, extensive omental adhesions were found, and solid masses were felt below and behind; the tumour, indeed, presented the appearance of a huge sarcoma. The trocar was plunged in at a place where the wall was thin and free of veins, but no fluid escaped; a second thrust was made at another spot with the same result, the contents being too viscous to come away. Every effort to reduce the size failing, the abdominal wound was extended upwards to within a couple of inches of the tip of the endoscopy, and the tumour was then turned out, the omental adhesions tied and separated, the pedicle tied with silk, the tumours released, and the peritoneal folds sutured over the stump. The uterus, small and rather elongated, lay towards the iliac fossa. During the toilet, and whilst the peritoneal edges were being sutured, some four pints of saline solution at a temperature of 105° to 108° F. were poured into the abdominal cavity. The incision was so long that the intestines could be seen floating about. The abdominal wall was closed by the three-layer method.

The patient bore the operation well, and did not suffer from shock. The tumour was of a multilocular cystic character, with very viscous contents, and weighed 22½ pounds.

The night following the patient passed an inordinate quantity of water, no doubt caused by the four pints of the saline fluid poured into the abdomen during the operation; she made an uninterrupted and uneventful convalescence.

I am gratefully indebted for these notes and to the care of the patient to my house surgeon, Mr. Archibald Leitch, and for the following pathological report on the specimen to Messrs. Plimmer and Morgan, pathologists to the Cancer Hospital.

The tumour, which weighed 22½ pounds, was a large cyst, with a solid mass of considerable size attached to one part of the wall. The cyst wall was smooth and showed no intra-cystic growths. Microscopically, the sections showed ordinary cystic growth lined with one layer of cells, and the main bulk of the more solid portion consisted entirely of degenerated material which would not stain, and in it there was very little that was cystic.

Cystic and Sclerotic ovaries removed on account of intense & persistent pain.

By Bedford Fenwick, M.D. (e)
Physician to the Hospital for Women, Bobo Squares.

The two sections which I show, by means of the epidiroscope, this evening have been made from the ovaries which I removed on October 28th from a patient in the Hospital for Women. She is a single woman, rt. 27, occupied at home, and was first sent to me by Dr. Munshé about a year ago. She had then been under treatment for nine years for a pelvic, and both felt ovarian regions, but especially on the left side. This pain was accentuated for three days before and during each period. She described it, at its worst, as if she were being stabbed with a red-hot needle, darting through into the back and down the left thigh and leg into the foot. The pain in the right side, and the rule also in the left, was described as of a dull, aching character. There was a frequency of nausea, and occasionally leucorrhœa. Otherwise, except that she had been losing flesh steadily for some months past, she made no other complaint. There was no apparent reason why she should simulate illness, and certainly the loss of weight, the increasing bodily weakness, and the frequently sleepless nights, whilst she was under treatment in the hospital, were not traceable to any other cause than the constant pain of which she complained. On examination, the cervix was found to be small and the os somewhat smaller than normal. The uterus was in front, small but normal in shape. Both ovaries could be felt, the left slightly lower than normal, and both felt hard. She had worn pessaries off and on without any beneficial result. She had taken many tonics and sedatives without any effect. Finally, as her health was evidently deteriorating, I took her into my wards, and she was carefully dieter, blisters and other applications were employed, and tonics administered for five weeks. Still she continued to lose flesh and strength, and the sister and nurses were persuaded that she actually suffered the constant and sometimes severe pain which she described. As a last resource, then, at her earnest request to have something done for her relief, I performed laparotomy. Both ovaries were slightly enlarged, the left had slight adhesions around it, the right was quite free. A colleague who was with me agreed that the ovaries were, to all outward appearance, healthy; and certainly to the naked eye there did not seem to be any obvious disease. Still, remembering her ten years’ suffering, her enfeebled general health, and the results which have followed in some half a dozen other similar cases, I removed both ovaries. During the operation she had no sleep at all; the following night and ever since she has slept well; better, she says, than she has done for many years. Since the second day after the operation, she has been

(e) Read at the meeting of the British Gynaecological Society on November 12th, 1903.
entirely free from any pain. She rapidly regained her appetite, lost the sallow, haggard appearance she had before, and is now quickly gaining flesh.

So much for the clinical features. Mr. Eastes has been good enough to make very careful sections of the ovaries for me, and I am indebted to him for those which I will now show by the epidiaskope. It will be observed that these ovaries, which seemed so healthy on the surface, are literally riddled with cysts, so that there is little ovarian tissue left. Moreover, the remaining stroma of the capsule and cystic degeneration, and in every one of these cases the patient was at once and permanently relieved of her pain; in every case the general health began to improve at once; and in no case in which the sleeplessness caused by the pain had led to a complete mental break-down, the patient was also cured of her maniacal anxiety.

With regard to the pathology of these cases, in each instance I have observed that the Fallopian tubes appeared to be quite healthy, but that the uterus was somewhat abnormally small, and in one case, in which I obtained some good sections, the ovarian artery appeared to me to be considerably smaller in its caliber than usual. If one accepts a fibroid thickening of the capsule as a feature of these cases, I suggest that it would explain the occurrence of cystic disease in consequence of the enforced retention of the Graafian follicles at each menstrual period, their development into cysts and the gradual destruction of the surrounding tissue by the pressure from behind. One of the other causes of a thickened peritoneal stroma and capsule may cause abnormal pressure on the ovarian nerves, and thus reflex irritation of the ovarian and hypogastricplexuses and of the sacral nerves. This particular patient, for example, could map out her sciatic nerve in tracing the course of the pain down the thigh and leg.

Finally, in the face of such cases as these, a practical question of much importance arises—whether, in fact, we are justified in permitting patients suffering from definite signs of ovarian nerve irritation to continue to suffer, year after year, without adopting radical treatment for their relief. I fully admit the gravity of the illness, but surely it is one which should be faced. I frankly confess that out of the hundreds of patients I must have seen with severe ovarian pains during the last twenty years, I have only had the moral courage to remove the ovaries in at most six cases, which I admit were extreme. But the results attained in those cases and the pathological condition shown in the present instance, make me doubt whether such strict conservatism is altogether justifiable.

A CASE OF INCARCERATED IRREDUCIBLE FEMORAL HERNIA IN A WOMAN. (a)

By ROBERT HUGH HODGSON, M.D.

A LADY, aged 48, the mother of four children, the youngest being now twenty-one, had suffered right femoral hernia for the last twelve years. She had worn a truss constantly. Six years ago the same rupture came to my notice, but it was left unattended, and a new truss applied. With the exception of occasional constipation and slight pains no inconvenience was experienced from the hernia until July 23rd of the present year, when the patient found a swelling in her right groin about six inches long and two broad, running parallel with Poupart’s ligament. She at first attributed it to the clay-pipe that the whole of the swelling had occurred within the last five days, I tried gentle taxis, but as no alteration was thereby effected, and there was no impulse on coughing, I ordered that the swelling be covered with ointment and a crushed linseed poultice applied over the ointment. A gentle purgative was given at short intervals. With the exception of relief from pain, no improvement was taken place by the next day, I advised taxis under anaesthesia, and explained to the patient that should I fail then to reduce the hernia it would be necessary to operate. On the 29th, chloroform was administered and taxis again tried, but without effecting a reduction. I therefore opened the sac and found the following condition: a knuckle of small intestine protruded from the crural canal, running straight down the thigh. On the inner side of this knuckle (that is to say, nearer the median line of the body) there was a pouch-like protrusion of the intestinal wall, about an inch and a half long, and on the outer side of the knuckle another protrusion, about two inches long, running outwards and upwards parallel with Poupart’s ligament and quite free in its sac. The bend in the gut forming the knuckle and the protrusion on the inner side were, however, firmly adherent to the sac. The neck of the sac was united to the surrounding structures for nearly the whole of its extent, the exception being the outer side of a small portion of the lower boundary. Here, then, arose my difficulty: What was the best course to pursue, to make an artificial anus, to open the abdomen and perform enterotomy, or to separate the two pouch-like portions from the sac and free the gut at the femoral ring? Having decided on the last course, I freed a small portion of the intestine from the wall with my finger, but found it necessary to dissect out the remaining intestine, leaving pieces of sac adherent to the gut. These pieces I pared off as closely as possible. Then, with the end of a Stanley director I was able to detach some of the intestine from the ring, and completed the separation with my finger. After division of the inguinal ligament I found it still impossible either to draw the intest-
tine down or to push it into the abdomen owing to the fact that it was adherent to the abdominal wall. Fortunately this attachment was not very firm, and gave way to digital pressure, and I was then able to return the gut into the abdomen. The ragged pieces of the sac having been cut away close to the ring, a purse-string suture was inserted round the edges of the opening, drawn tight, and tied. The course of Hesselbach's ligament was next stitched to the fascia covering the pectineus, and the wound closed.

The patient made a complete recovery, and the bowels act regularly and well. I have brought this case before you, believing it to be interesting for the following reasons: The patient's positive assurance that the hernia had been down only a few days; the extensive adhesions both in and outside the abdomen; the peculiar shape of the protruded bowel, which was that of an irregular cross; and the all-important question of the selection of operation.

THE RADICAL CURE OF A RECURRENT VENTRAL HERNIA. (a)

By INGLIS PARSONS, M.D.,
Physician to the Chelsea Hospital for Women.

This patient, a woman, aged 36, had for many years suffered from diseased appendages. In March, 1898, she was taken into one of the provincial hospitals and both appendages were removed, and soon after leaving the institution she noticed a swelling in the scar left by the operation. In September, 1898, she was readmitted, and the same surgeon operated on the hernia. In January, 1899, the swelling again appeared in the same place, and she then decided to come into the Chelsea Hospital for Women, and was admitted under my care in April, 1899.

On admission, the patient, who was a strong, stout woman, was found to have a ventral hernia about the size of a large orange in the middle line between the umbilicus and the pubes. The separated edges of the muscles and aponeurosis formed a well-defined ring about three or four inches in diameter.

Menstruation had not ceased since removal of the ovaries, but had become irregular, sometimes profuse, at other times scanty.

On May 4th, ether was administered, and with the assistance of Dr. Berkeley the abdomen was opened by a curved incision along the edge of the ring formed by the muscles and aponeurosis. This course was adopted because, as a rule, either intestines or omentum are found to be adherent in the middle line to the scar left by the old incision. This was cut with a cautery ligature, and the peritoneum, consisting chiefly of peritoneum and skin, was then removed. The fibrous tissue in the ring, which matted together the layers of the abdominal wall, was pared away until each layer could be distinctly made out and separated. The peritoneum was first united with a continuous fine silk ligature, and the cut ends were turned in the wound, so as to avoid leaving a raw surface in contact with intestines or omentum. The muscular and fibrous layers were next united with interrupted silk-worm-gut sutures. As these are the most important in preventing hernia, and are left buried, great care was used to ensure that fascia and muscle were united accurately together on each side. The skin and subcutaneous tissues were next united by interrupted silver wire sutures.

The temperature remained normal after the operation, and she made an excellent recovery. She was discharged from the patient November, 1900, eighteen months after the operation, and she keeps quite well, and is able to earn her living by acting as an insurance agent, which entails a good deal of bicycle riding through the country.

Remarks.—At the first two operations the patient tells me that the abdominal incision was united in a single layer. As she is a very intelligent woman, and received her information from the nurse, I have no reason to doubt it. My own success I attribute entirely to sewing up in three layers and using buried silk-worm-gut for the muscles and aponeurosis.

The difficulties in these cases are, first, the adherence of bowel or omentum to the old cicatrix; this is met by avoiding the middle line and making a curved incision to the side; the flap can then be turned back, and anything adherent separated with ease; and secondly, the matting together of all the layers round the edge of the ring. This is met by removing the fibrous tissue from the ring and by prolonging the incision a little above it, so as to get into the normal layers as they are found on first opening the abdomen.

THE AFTER-TREATMENT OF INTRA-NASAL OPERATIONS.

By Sir FELIX SEMON, C.V.O., M.D. (a)

The lecturer began by saying he should limit his remarks to intra-nasal operations, particularly those undertaken for the relief of nasal stenosis, and should entirely exclude those performed for disease of the accessory and naso-pharyngeal cavities. Although impossible to be performed strictly aseptically as in most other regions of the body, yet it would be the duty of every operator to take all possible precautions, such as sterilising instruments, dressings, &c. Local anaesthesia (i.e., cocaine) would be preferred in the great majority of operations, as it was essential for the patient to be sitting upright, so that the operator might see clearly at every moment exactly what he was doing. This outweighted all claims in favour of general anaesthesia. With regard to the use of adrenalin, he was under the impression that since he had used adrenalin in these cases he had heard, more frequently from patients of the occurrence and persistence of haemorrhage than in previous times. For the prevention of adhesions, the advantages and disadvantages of plugging were referred to, the opinion being expressed that plugging was apt to produce considerable irritation, to cause local anaemia of the injured parts, and thereby to prevent healthy healing. With the view of diminishing (though it did not actually prevent) inflammation, in the present instance consisting of three grains of cocaine and half a drachm of boric acid in six ounces of water was recommended three or four times daily. For prevention of secondary haemorrhage, firm plug-
ging should be avoided, as it did not with certainty prevent it, as such hemorrhages might, and did, often occur when the tampon was removed on the day after operation. If there were no reason to expect considerable hemorrhage, he used no plugging, but ordered the boric and cocaine spray previously indicated. If the wound should be at all extensive, a strip of cyanide gauze soaked in a solution of hydrogen peroxide was introduced with the view of preventing subsequent hemorrhage. If bleeding occurred the patient should be directed to apply cold water compresses over the nose. The advice that the patient should inspire deeply with closed mouth, and slightly expire with open mouth, would also be found very useful. In some cases, of course, powerful stysptics and energetic plugging by means of Bell's cautery might be found to be indispensable. Meddlesome interference, such as washing out, was deprecated as being usually superfluous, sometimes even prejudicial to healing. If there were risk of the formation of adhesions more active treatment would be required, the nasal cavity should be rendered patulous. By permitting the breathing of a patent, by means of cocaine or adrenalin, the cicatrized bands should be divided by cutting instruments (not with a probe), and a piece of gutta-percha paper introduced into the nose.

The Out-Patient Departments.

CARDIFF INFIRMARY.

Some Clinical Remarks on the Diagnosis of Anæmia and other Causes of Intra-Thoracic Pressure.

By W. MITCHELL STEVENS, M.D., M.R.C.P.Lond., Assistant Physician and Pathologist to the Cardiff Infirmary.

(Concluded from page 530.)

CASE 6.—A man, aged 42, complained of pain in the upper part of the right chest and about the right shoulder. There were no other symptoms of pressure, but an anæmia was discovered in the ascending part of the aortic arch.

CASE 7.—A man, aged 41, with a history of acute rheumatism two years previously, complained of shortness of breath for some months which was followed by alteration in the voice and by paroxysms of distressing breathing. An examination showed not only anæmia, but also both aortic and mitral valvular disease. A few days after being under observation he developed somewhat suddenly swelling and cyanosis of the head, neck, and upper part of the chest.

CASE 8.—A man, aged 35, had complained for eight months of some dyspnoea and cough. He was supposed to be suffering from bronchitis. Rather acutely he developed a noisy difficulty in breathing, but his voice was unaffectted. In this case physical examination showed nothing; the pulses and pupils were equal and there were absolutely no signs of anæmia, nor were there any laryngeal symptoms or pain. A large anæmia was found springing from the descending portion of the aortic arch.

CASE 9.—A woman, aged 41, came with what she called 'asthmatic attacks' and shortness of breath on exertion, with an irritating and ineffectual cough. There was no pain nor dyspnoea. The cough had a peculiar indescribable "tone," and was associated with paroxysm of the left vocal cord. Physical examination showed absolutely nothing, but the autopsy revealed a small anæmia in the third part of the arch of the aorta posteriorly.

Each of these cases illustrates some point in the clinical diagnosis of intra-thoracic pressure. In all cases of obscure symptoms or physical signs in connection with the chest there is one question which ought always to be considered viz., Are any symptoms or signs of intra-thoracic pressure present? These have already been referred to, but it is necessary to remember that they may be slight or very marked, and that they are apt to be obscured by other symptoms and signs pointing to disease of the lung itself. The main point is, therefore, to consider if there be any symptoms present which may be due to pressure and which would then indicate disease in the aortic arch. Having, then, arrived at a certain probable or possible diagnosis of intra-thoracic pressure, the next question is, What is the cause? In answering this it is first necessary to bear in mind that syphilis may be the cause of tracheal or bronchial obstruction. Frequently in unusual cases of thoracic disease the possibility of the presence of this affection is not to be lost sight of, for it may produce both inspiratory dyspnoea and laryngeal symptoms.

Excluding mediastinal abscess, which may be due to tuberculous disease of the bronchial glands, and the so-called mediastinoperticarditis, which may cause pressure upon the superior vena cava, inspiratory swelling out of the veins in the neck and the so-called "paradoxus" we have left as the three following affections: (1) Anæmia, (2) mediastinal tumour, (3) enlargement of the bronchial glands. The latter condition (bronchial phthisis) is not uncommon in children and may produce difficulties. The breathing of a patient so affected is called "asthma," and also a "croppy" cough, with, perhaps, other symptoms both general and local. In such cases some slight physical signs may be found over the upper part of the manubrium or in the interscapular space.

The main difficulty, however, in the differential diagnosis of the cause of intra-thoracic pressure lies between anæmies and mediastinal growth, and in such cases the following points may be considered in arriving at a conclusion when the nature of the affection is doubtful. (a) Age. If the patient be under twenty-five it is probably a mediastinal growth. Anæmia is most common in middle life. (b) Sex. An anæmia is rare in women. (c) Occupation. A laborious occupation predisposes to anæmia. (d) History. A history of syphilis may suggest anæmia, while one of malignant disease or of lymphadenoma suggests a mediastinal growth. (e) Symptoms. Where pain in especially in the back, is common in anæmia. Dyspnoea as a primary symptom suggests a growth commencing from the esophagus. It is also seen in anæmia, but, on the whole, is rather more frequent in indicating mediastinal affection. Laryngeal symptoms are met with in both, though they tend to be rather more urgent and marked in anæmia. Hæmoptysis may be present in both affections, but is more common in growths, especially where the lungs are involved. Pyrexia, though often absent in both diseases, is more often seen in growths. Wasting and cachexia vary very much and are often absent in tumours for a considerable time, while they may be marked in some cases of anæmia. If very distinct, they would rather suggest growths. (f) Physical signs. Edema and dilatation of veins from pressure are commoner in growths. Inequality of the pulses is more frequent in anæmia. Tracheal tug- ging points to the latter affection, while enlarged glands in the neck or axilla are indicative of growths. The absence of all physical signs may be seen in both, but is more suggestive of anæmia. The limitation of the physical signs to the region of the aorta and the presence of localised bulging, pulsation, thrill, or diastolic shock point to anæmia. Extensive dulness in various parts or over the whole of one side of the chest and the presence of a pleural effusion is indicative of growth. It is always to be remembered that pleural effusion is often secondary to a mediastinal growth, and that the only physical signs present may be those of effusion, and the combination of this sign with symptoms of an unusual character, especially those pointing to anæmia. In the latter cases the effusion contains blood, and when it is drawn off the symptoms are but little relieved. Careful examination may then,
SPECIAL ARTICLES.

Nov. 25, 1901.

Perhaps, determine the presence of signs which corroborate one's suspicions.

In conclusion, it may be said that the diagnosis of intra-thoracic pressure is not, as a rule, difficult if its possible presence be borne in mind and a careful examination be made. The reason that it is so frequently overlooked is because it may come under observation before obvious physical signs are present and because the weight is not given to the symptoms.

BRITISH SANATORIA FOR CONSUMPTION.--XXI.

BY OUR SPECIAL MEDICAL COMMISSIONER.

BRIGHTON'S MUNICIPAL SANATORIUM.

Sanatoria for the isolation, education, and treatment of sufferers from pulmonary tuberculosis are rapidly springing into being in all parts of the civilised world, and in this country remarkable progress is being made in the establishment of institutions for the hygienic management of phthisical cases. The results of sanatorium action certainly seem to indicate that in the so-called open-air treatment we have arrived at the most satisfactory method hitherto known of combating pulmonary tuberculosis. And yet it must be admitted that for many reasons the institutional treatment of phthisis should be considered as still in the experimental stage.

Many more or less satisfactory sanatoria are available for the well-to-do, but for the vast number of sufferers among the so-called working classes adequate accommodation is exceedingly meagre, and at present for the indigent and pauper consumptives there are very few suitable establishments.

This is not the place to discuss the various measures advocated for a successful warfare with tuberculosis, and now receiving the careful consideration of sanitary authorities in this country; but we wish to draw attention to what must be considered a most interesting experiment in the provision of what may be termed an educational municipal sanatorium.

It seems likely that in the near future the Metropolitan Asylums Board may undertake the treatment of Leproles, phthisical cases; and already Councils, Borough Councils, Boards of Guardians, and other public bodies in various parts of the country have provided, or are taking steps to secure, hygienic treatment for tuberculous cases arising within particular areas.

The position taken by the Borough of Brighton, acting under the advice of its distinguished Medical Officer of Health, Dr. Arthur Newsholme, is of great interest.

As is well known, a system of voluntary notification has been at work in Brighton since 1899, with considerable measure of success; and in the provision of an educational municipal sanatorium London-by-the-Sea may well claim pioneer rank.

In July of 1902 phthisical cases were first admitted to one of the pavilions of the Borough Fever Hospital. Further accommodation has been rendered available, so that at the present time there is one ward for male and another for female cases.

We have carefully inspected the portion of the sanatorium devoted to the phthisical cases, and consider it well adapted to their needs. The situation is somewhat exposed and open to winds, but a large and well protected day shelter is available for the men and smaller ones are reserved for the women.

Great care is taken to carefully train the patients in hygienic routines. The dietary is abundant and well selected. A trained nurse is always in attendance. Every patient is kept under strict medical supervision. Careful notes are taken of every case. Treatment is conducted in strict accordance with the best hygienic methods.

It is necessary, however, to point out that while everything is done to provide means for improving the condition of each individual, the main object of the sanatorium is to secure advantage to the public. As Dr. Newsholme points out, "Apart from the possibility of curing such patients it is in the public interest to admit consumptive patients not living under favourable conditions to the Borough Sanatorium for a month or two, according to circumstances. It will diminish disease and improve the public health in three ways:—1. The patient himself will be improved, and enabled to start afresh with a good prospect of recovery; (a) while he is in the sanatorium his house can be cleansed and purified, his wife and family will have a holiday in the sense of being free from repeated attacks by the infective material causing consumption; (3) The patient, when sent home, will have been taught and warned how to prevent the disease spreading and giving a holiday to his family and to those with whom he works."

Dr. Newsholme has recently reported to the International Congress of Hygiene and Demography at Brussels as to the results obtained at the sanatorium, and as far as we have been able to judge they must be considered eminently satisfactory.

The main feature of this effort is its important educational aspect. The "Precautions for Consumptive Persons" issued by Dr. Newsholme are so sound, simply expressed, and comprehensive that we make no apology for quoting them.

The consumption is, to a limited extent, an infectious disease. It is spread chiefly by inhaling the expectoration (spit) of patients which has been allowed to become dry and float about the room as dust.

"Do not spit except into receptacles, the contents of which are to be destroyed before they become dry. If this simple precaution is taken, there is practically no danger of infection. The breath of consumptive persons is free from infection, except when coughing."

The following detailed rules will be found useful, both to the consumptive and his friends:

1. Expectoration indoors should be received into small paper bags and burnt immediately.

2. Expectoration out of doors should be received into a suitable bottle, to be afterwards washed out with boiling water; or into a small paper handkerchief, which is afterwards burnt.

3. If ordinary handkerchiefs are ever used for expectoration they should be put into boiling water before they have time to become dry; or into a solution of a disinfectant, as directed by the doctor.

4. Wet cleansing of rooms, particularly of bedrooms occupied by sick persons, should be substituted for "dusting" and sweeping.

5. Sunlight and fresh air are the greatest enemies of infection. Every patient should sleep with his bedroom window open top and bottom, a screen being provided, if necessary, to prevent dust entering if possible occupy a separate bedroom. The patient need not fear going out of doors in any weather if warmly clad.

6. The patient himself is the greatest gainer by the above precautions, as his recovery is retarded and frequently prevented by renewed infection derived from his own expectoration.

6. Persons in good health have little reason to fear the infection of consumption. Over-fatigue, intemperance, bad air, dusty occupations and dirty rooms favour consumption.

Although it may be thought that the description of such an institution as the Brighton Borough Sanatorium for Consumption hardly comes within the scope of this series of articles, we are nevertheless of opinion that it merits much attention, since it indicates the progressive trend of thought in this direction which is forcing sanitary authorities into practical efforts, not only to attempt the cure of the patient, but to secure means for the adequate protection of the public.

Royal College of Surgeons in Ireland.

FELLOWSHIP EXAMINATION.—The following candidates have passed the primary part of the Fellowship Examination:—Mr. F. Foran, Dublin; Miss C. E. O'Meara, Dublin; Mr. H. I. Perrv. Cork; and Mr. H. Stevenson, Belfast.
Transactions of Societies.

BRITISH GYNECOLOGICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 12TH, 1903.

DR. HEYWOOD SMITH, President, in the Chair.

DR. F. A. PURCELL exhibited a large multilocular ovarian cyst; notes of the case will be found on page 584.

DR. BEDFORD FENWICK, by means of the epidiasecope, showed sections of ovaries removed from a young woman for pain persistent for ten years; an account of the case will be found on page 585.

Dr. Inglis Parsons said that he entirely agreed with the views expressed by Dr. Bedford Fenwick. Some years ago much obliquity was cast upon a well-known and esteemed surgeon in Liverpool for removing ovaries, as it was alleged, unnecessarily; now unfortunately the pendulum had swung too much in the other way, and the surgeon sometimes held his hand when it would be far better to remove the ovary. One had, of course, to be careful that the patient was not so hysterical or hysterical, that her symptoms could not be attributed to the condition of her nervous system, but when that had been ascertained, and other treatment had had a fair trial, one was certainly, on the evidence of any enlargement of the organ, justified in removing the ovary.

Dr. G. R. Hodgson said that he was much interested in the case in connection with one he had brought before the Society last year, in which the patient, in spite of treatment by various medical men and in hospitals, had been constantly suffering pain for seventeen years after he had first seen her, but from the day he removed the ovaries all pain ceased, and her recovery was complete. He had been somewhat reluctant to perform the operation, as in another case of the kind, some ten years ago, the pain did not entirely disappear, but the result in the one operated on last year had been most satisfactory.

The President thought they were indebted to Dr. Bedford Fenwick for bringing the case, and the condition of things it exemplified, to their notice. He was sure that there were many cases of ovarian suffering in which the ovaries did not attain a size much larger than normal, as, for instance, in the two cases he had himself described at their last meeting, in which the ovarian stroma had been extremely dense. No doubt abdominal pain did sometimes persist after the operation, perhaps owing to the inclusion of a nerve in ligaturing the pedicle, but such pain, he thought, generally disappeared in time.

Dr. Bedford Fenwick said that he had hesitated to bring forward the case because, though he had met with numerous cases of the kind, he had not had the moral courage to operate upon more than five or six. He thought Dr. Parsons was right in saying that the tendency now was in the opposite extreme to that of thirty years ago, and that the operation was now too seldom performed for the condition described. The patient in the case he had reported was only twenty-seven years old; he had kept her under observation in the hospital for five weeks before doing anything; even at the operation, both to Dr. Stevens and himself, the ovaries seemed to the naked eye to be fairly normal, and it required some resolution to remove them simply on account of her sufferings; now, however, she was greatly dissatisfied because they had not been removed sooner.

The President showed, with the aid of the epidiascope, a section of the remarkable fibroid tumour in calcaneous degeneration, which he had brought before the notice of the last meeting of the Society.

Dr. G. R. Hodgson read notes of a case of INCARCERATED AND IRREDUCIBLE HERNIA IN A WOMAN, which will be found on page 585.

In reply to Dr. Hodgson, who had arrived at the conclusion that the hernia was irreducible; if so, was it safe to give even a gentle purgative? He had always understood such treatment to be very doubtful, indeed, very dangerous. Dr. Hodgson, in reply, said he had relied upon the history that the hernia had come on a few days previously, and could not anticipate that he would find it all glued together. He had therefore felt justified in attempting to soften the motions in the hope of emptying and reducing the bowels; he had not considered it irreducible until the operation.

Dr. Inglis Parsons read notes of a successful operation for the cure of a large ventral hernia, which will be found on page 584.

Dr. Parsons, in reply to a question of the President, said that the hernia had occurred twice. The patient had been operated upon for it in the hospital in which the abdominal section had been done to remove her appendages; the hernia recurred in the same spot within three months, and it was for the recurrence he had operated. It would have been very difficult to separate the layers of the abdominal wall, which were, as usual, firmly matted together; one had not cut away the walls, but had cut away the base, and then the patient was then able to find and unite the layers, as after an ordinary section of the abdominal wall for the first time.

LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, NOVEMBER 6TH, 1903.

The President, Dr. P. McBride, in the Chair.

SIR FELIX SEMON, C.V.O., M.D., opened a discussion on the AFTER-TREATMENT OF INTRA-NAVAL OPERATIONS, an abstract of which will be found on page 584. Dr. Scanes Spicer considered it necessary to give a general anaesthetic in these cases in order to do all that was necessary at once, instead of proceeding by piecemeal operations under cocaine anaesthesia. He referred to alar collapse and rigidity as a cause of prolonged after-treatment, which he was in the habit of dealing with by forcibly stretching with a screw dilator.

Dr. StClair Thomson said that the best way of avoiding the difficulties of after-treatment was to take precautions before operating, with regard to the preparation of the patient, the surgeon, and the operator. It was of the highest importance to avoid powders and plugs, and to bear in mind that fresh blood was itself a germicide. The attempt to make antiseptic powders or lotions in the nose have any germicidal effect was futile, for the Schneiderian membrane would tolerate no active bactericide.

Mr. Cresswell Barber was convinced that the lesson that was done to the nose after operation the better. He did nothing more than place a light plug of antiseptic wool in the vestibule, which was frequently changed. If there were any fear of adhesions, he passed a probe through the cavity once a week or instructed the patient to pass for himself a thin bone spatula, 9-16th in. in. width, through the nasal cavity, two or three times a week. He thought that in only two circumstances was it necessary to leave a foreign body in the nasal cavity after operation, viz., in case of haemorrhage, which was rare, and to retain in place a reflected septum which had been divided and pushed into a more normal position.

Dr. Bronner advised syringing the nose after operation with a 4 per cent. solution of bicarbonate of soda. This relieved pain, and prevented the formation of crusts. Should there be streaming of crusts and applied trichloracetic acid. He thought it dangerous to give a general anaesthetic when the patient was in a sitting position. He advocated the use of an antiseptic mouth wash, as a septic mouth very readily gave rise to suppuration after nasal operations.

Dr. H. Tilley was of opinion that general anaesthesia was advisable for the satisfactory performance of intra-nasal operations. When he was asked whether he agreed to adhesions, he was of opinion that they were generally the result of wounding the opposed surface. In removing a septal
spur it was easy to unconsciously abrade the mucous membrane of the opposite turbinal, and thus an adhesion would almost certainly result if a suitable plug were not inserted. Normal mucous membrane could never unite with a granulating surface. He thought the use of adrenaline predisposed to secondary haemorrhage.

Dr. Watson Williams said that for the prevention of adhesions he had had a speculum made with long ivory blades, which were adjustable, so that either blade could be made from an inch to an inch and a half longer than the other. This enabled him, when inserting the speculum on either side, to expose one side of the nasal cavity while it protected the other. He thought that in using the cautery, the opposite side, though not actually touched by the cautery point, was apt to be scorched by reflected heat. He was of opinion that the tendency to haemorrhage was increased by the use of adrenaline.

Dr. Dundas Grant said the anxiety attending nasal operations depended upon the possibilities of haemorrhage, local or general sepsis, the formation of adhesions, insufficient result from removal of too little tissue, or persistent crust formation, and dry pharynx from removal of too much. He avoided plugging, if possible. In galvano-cauterisation he thought he had been fortunate in avoiding the formation of adhesions. His plan was to introduce the cautery point under the mucous membrane, and withdraw it at a red heat. This submucous puncture could be repeated at several spots. The punctured spots were then painted with dilute quenching trichloracetic acid (which appeared to produce an antiseptic seal); the whole turbinale was then brushed with a 10 per cent solution of antiseptic, which kept it in a state of contraction for several hours, and, lastly, a little aristol or euraphen insufflated was calculated to form an antiseptic barrier between the operated surfaces.

Dr. Doneelan thought that synchisium could be certainly avoided only by ensuring adequate separation at the time of operation either by the removal of sufficient tissues, the use of suitable splints, or by both. The successful after-treatment of intra-nasal operations depended not only upon the manipulative skill of the operator, but on the judgment and mechanical ingenuity with which he devised modes of procedure suited to individual peculiarities.

Dr. Furniss Potter had had considerable experience with adrenaline, and had not had any trouble with haemorrhage after its use. He admitted that he had been in the habit of plugging with gauge, which he usually left in the nose for from six to twenty-four hours after operation. If an hour, or half an hour, previous to removal, the gauge were moistened with a spirit of camphor and of hydrogen, and then carefully withdrawn, bleeding would be avoided.

The following members also joined in the discussion: Dr. W. Hill, Mr. E. B. Waggett, Mr. Hunter Tod, and Dr. L. H. Pegler.

**France.**

*From our Own Correspondent.*

Paris, November 22nd, 1905.

**Blood-letting.**

In passing in review the history and modern indications of blood-letting Professor Garry said that the oldest medical writings mention it, and long before Hippocrates Greece and Africa claimed the honour of their discovery. Hippocrates recommended bleeding provided it was moderate, but Erasistratus proscribed absolutely the operation, as, imbued with the ideas of the Pythagoricians, he placed the seal of the soul in the blood. In more modern times, however, Galen was the recognised partisan of blood-letting. For the doctor of Pergamus the humours could be vitiated in various ways, and Nature required frequently to be aided in the evacuation of the offending humours, but he was an adversary of the abuse of removing the sanguine liquid.

In the Middle Ages, blood-letting was carried to extremes. According to Riclaf a patient could lose without danger the half of his blood, while Botal recommended that two or three quarts of blood should be drawn at each seance. Guy Patin bled thirteen times in a fortnight for pleurisy a boy of seven years old. Later, Harvey made a strenuous opposition to blood-letting, taxing his contemporaries with exaggeration and calling them "sanguinary pedants."

With Quenay, Bocquignon, Franck, and Brousais, and above all Bouillaud, the practice of blood-letting recovered its former vigour.

If the first quarter, or rather the first half, of the last century might be justly accused of "hematomanie" it seemed that the second half fell into the contrary excess, that of "hematophobie," so that many practitioners of the present generation never bled any person nor perhaps saw any operation of the kind.

First extolled as a universal remedy, afterwards regarded as a terrible pest, blood-letting seems for the last few years to be coming back to favour.

Commenced in France with Vinay (1880), continued by Huchard, Thierry (1887), Dujardin, Jacquot, Raymon, &c., the movement spread in Germany (Kroeging, Alba, 1896; while three reports were presented on the subject at the Congrès de Médecine (1900) by Hayem, Boginski, and Robin.

According to these authors it was concluded that whereas formerly bleeding was practised against the entire morbid evolution, to-day it was regarded as an urgency (moyen d'urgence) against the complications of a disease and not against the disease itself.

Thus conceived and practised, blood-letting deserved the esteem of practitioners; and the sage moderation, together with the method observed in the limitation of its employment, guaranteed a modest but durable fortune in the future.

By blood-letting the tension is lowered progressively, and when the vein is closed the pressure rises slowly, and at the end of twenty-four hours it remains fixed at a point slightly inferior to that before the operation. The depletive mechanical action is one of the most manifest and the most incontestable effects of bleeding. In opening the vein of a patient suffering from dyspnoea and cyanosis from insufficiency and dilatation of the right ventricle, an immediate and progressive relief is produced, the respiration becomes easier and deeper, the heart becomes more regular, the beating diminishes in frequency, cyanosis disappears gradually and the patient comes back to life. Not only does bleeding act in the above mechanical manner, but it plays also a purifying rôle. In the normal state the toxins fabricated in the organism are destroyed and eliminated by certain organs, essential conditions to the maintenance of health. When one of these organs fails, a series of troubles is immediately produced, which may become extremely grave after a certain time.

In removing from the organism a certain quantity of blood, toxins are drawn away at the same time, and Bouchard has demonstrated that an ounce of blood taken from a person suffering from uremia contained ten grains of extractive matter or 1/16th of the total quantity of these matters contained in the urine of a whole day.

As regards the affections benefited by bleeding, the number is not very large, but, on the other hand, the indication is precise; those where the tension is exaggerated or which are characterised by the intensity of the congestive phenomena and poisoning of the blood. But it should be always borne in mind that
blood-letting should be regarded as an emergency
operation directed against a threatened complication,
the treatment of a symptom and not of a disease.

Among the maladies where blood-letting is clearly
indicated may be mentioned cardiac thrombosis as a
complication of mitral insufficiency, dilatation of the
heart, acute oedema of the lung, uræmia, puerperal
eclampsia, hyperæmia of the nervous centres, meningitis,
congestion of the brain with threatened haæmorrhage,
pneumonia in young and vigorous patients, renal
sclerosis, and so on.

The dangers of blood-letting, says Professor Garr,
will render good service, as nothing could replace it in
the moment of imminent danger. If the greater or less
frequency of its employ be subjected to controversy,
the operation itself should be admitted, and if the
practitioner refrained from it, let at least his conduct
be not instigated by either fear or contempt.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, November 21st, 1903.

At the Medical Society Hr. Abel read a paper
entitled

THE VAGINAL OR THE ABDOMINAL ROUTE IN
GYNECOLOGICAL OPERATIONS?

He referred in laudatory terms to Dührssen's interesting
efforts in the introduction of the vaginal route in
gynaecological surgery. That laparotomy was not an
ideal operation was shown by the fact that the mortality of
it varied between 4% and 10 per cent. The chief
dangers of abdominal section were infection from the
air, shock from contact and dragging on intestine, and
post-operative ileus. The evil results that might follow
afterwards were then enumerated.

For various reasons the vaginal route has been looked
upon as unsurgical, one being that the field of operation
was not properly visible, another the uncertainty
about arrest of haæmorrhages. The speaker had himself
been impressed with these objections, and had for a
time in consequence abandoned the route. When he
returned to it, however, with greater energy he had seen
that all objections were due to defective technique.
When this was once overcome all these objections would
vanish. Experience had shown that when the vagina
was operated on in the usual imperfect way, only the
peritoneum took no harm from infection; the dragging
on the uterus, even when it was brought to the vulva,
was not greater than when it was pulled up to the
abdominal wall.

Generally, the whole operation could be carried out
under the guidance of the eye. The lighting up of the
field of operation and exactness of arrest of haæmorrhage
could only be obtained by the use of threads and not
forceps.

Large cystomata could be removed per vaginam, but
the route was not suitable for the extirpation of malignant
and solid ovarian tumours.

He had performed 121 vaginal coeliotomies with only
two deaths.

It was easier to persuade patients to submit to
vaginal operations than laparotomies, they could there-
fore be operated on earlier, and this was of special
importance in the case of myomata. These were not
in a proper sense malignant; but independent of mali-
gnant degenerating adenomyomata and myosarcomata,
they had an enormous influence on the organism, and,
especially in recent years, if the heart was prone to early serious changes. The
vaginal route permitted extirpation to be carried out
with comparative safety.

At the Society for Internal Medicine Hr. Tobias
brought forward a case of
EARLY DIAGNOSIS OF AORTIC ANEURYSM BY RÖNTGEN
ILLUMINATION.

A farmer, aged 42, had been treated for obstinate
intercostal neuralgia for a long time. He was healthy
previously, had never had syphilis, and was moderate
in the use of alcohol. He was married and had three
healthy children. In the spring of 1902 he felt a
peculiar cold spot between the left shoulder-blade and
the spine, which became the seat of a prickling pain later
and a numbing sensation. Various rubbings, electricity, morphia, had
been used, but without effect. At the commencement of
1903 he was sent to Carlsbad on account of enlargement of
the liver. There he lost 16.5 kilogrammes in weight;
the pain got worse and spread to the front. The man
could no longer lie on the left side, the whole of the
sixth intercostal nerve was affected. Electricity was
again tried, but with no result. He now came under
the speaker's treatment. The heart and lungs were
then normal, only the second aortic sound was a little
musical; no abdominal dulness about the thorax,
no arterial sclerosis that could be felt, no albumin in the urine, and no disturbances of sensation.

It was now suspected that the pain was from pressure of
a tumour, possibly an aneurysm of the descending aorta,
but objectively this could not be made out. Röntgen
illumination, however, confirmed the diagnosis—aneu-
rysm of the descending aorta.

A discussion took place on the

INTERESTING CANCER CASES

shown by Hr. Westenhöffer at the previous meeting, in
connection with which Hr. Gottschalk showed a very
rare preparation of carcinoma of the stomach which
had developed on a myoma, and was limited to it in
its growth. It was removed by vaginal extirpation from
a patient, aged 77, without narcosis and with no expression of pain on the part of the patient, who
recovered easily from the operation. She was dis-
charged on the twentieth day after the operation, and
soon afterwards she died of cerebral hemorrhage.

Hr. Adler spoke of the case of gastro-entero-
stomy for carcinoma of the stomach in which case
the Murphy's button remained behind. The patient
at first felt very well, could bear any kind of food, and
had increased 15 kilogrammes in weight. That this
could not long continue was foreseen, as the disease was
malignant. That the falling away again was not due
to the Murphy's button was evident by the fact that
the button was afterwards found lying free in the
stomach, and not in any way interfering with its func-
tion.

Hr. Westenhöffer observed on the remark of Hr.
Kraus regarding the invasion of coli bacilli in the case of
pachymeningitis carcinomatosa, that it was not to be
looked upon as etiological, but was an accidental
symptom. Large metastases were found in the whole
bonny system. Albrecht, of Munich, had drawn attention
to the question whether the onset of fever might not be
made use of from a differential diagnostic point of
view. With extensive metastases fever was met
with without any mixed infection.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 21st, 1903.

SYphilis or CANCER?

At the Gesellschaft der Aerzte, Turc presented a
female patient with all the phenomena of recent
syphilis, although the case was shrouded in much ob-
scurity.
The syphilitic theory was sustained by an induration on the anterior margin of the labium of the portio, swelling of the glands in different parts of the body, and exanthemata with scabs, the result of gumma. The ciliary portion of the left eye appeared to have disappeared entirely from the effects of a gumma. The patient was quite sound up to Christmas, 1902, when she gave birth to the seventh child; all the children were perfectly healthy. From the history of the case it would appear that the infection was not suspected till the month of May, from which time it has assumed all the appearance of malignancy running a rapid course.

Jungmann presented another case, at 44, a joiner’s labourer, who acquired syphilis six weeks ago in the form of a scerosis on the penis.

Five weeks later large papular syphilides appeared all over the body. As a cause of this unusual appearance it was noted that the drunken habits of the patient had much to do as a potent factor.

Incomplete Potosis.

Elschnig exhibited photographs of nine cases of shortening of the levator palpebrae superior to remove incomplete ptosis. He further showed another case of complete ptosis which he had repaired by Hess’ modification. This method was accomplished by passing a thread through the frontal muscles and raising the upper lid. The modification was performed with a piece of magnesium wire with this thread, which supported more of the fibrous tissue.

Königstein remarked that he thought this modification of Elschnig’s would prove to be a good one, but reminded the meeting of a method by Motais that had been very little used in surgery. His method was to free the rectus from its attachments and unite directly with the tarsus by stitches.

Chrysa of Argentum Colloidal.

Löbl reported the success of injecting into the bowel Credé’s colloid of silver in cases of sepsis, erysipelas and other purperal conditions. His method of operating is to dissolve 0.15 to 0.3 grammes of the colloid substance in 750 grammes, or two to three grains in 23 ounces of water. This ought to be repeated within eight days.

Schesinger reported a few excellent results from rectal injections, and highly commended Löbl’s prescription. The intravenous method was difficult if not dangerous in individuals with large quantities of fat, which greatly narrowed the superficial veins, thus making it a difficult task to enter them at any particular place.

Gastric Cancer.

Ullmann brought forward two female patients on whom he had operated very successfully for cancer of the stomach.

The first, at 62, began to complain about the autumn of 1902. She was operated on about the middle of June this year, when the whole of the stomach was removed and the jejunum drawn up and attached to the cardiac end of the stomach. Since that time the patient has expressed herself as perfectly well, and has lost 33 kilograms to her weight.

In the second case the whole of the small curvature of the organ was removed, giving the whole the appearance of a continuous tube or bowel. She is also well.

Tapping the Pericardium.

Ilothersen exhibited a young coachman, at 20, on whom he had successfully operated for hemorrhage into the pericardium. This is no new operation, as hundreds have already been performed, with the very high death-rate of 60 per cent.

He also showed another young man, who had been stabbed in the thorax with a knife, producing hemoptoemnothorax and wounding the cystic duct. Owing to the thinness of the walls of the latter, stitches were inadmissible and tampons had to be used, with perfect success.

Appendicitis.

Spieler next showed an anatomical preparation which he had removed from the pelvis of a young girl, at 12. The appendix was perforated by a bent rusty needle about a point. How the crooked needle was reached the appendix is hard to explain. The patient is now well.

Removal of Intra-Cranial Foreign Bodies.

Domeny reported an experiment he performed on animals with intra-cranial foreign bodies, such as small shot. In one case the shot was only one millimetre in diameter, but by the help of the König ray it was easily removed in less than three minutes, the animals afterwards remained reactionless.

Holzknecht told how he had operated in the same way with the radioscope in dividing one of the columns in a case of hemiathetosis; also in neuralgia, due to central disturbance; puncture of cerebral abscesses, as well as injecting medicaments into the cerebral centres.

Bazin-Hutchinson Summer Eruption.

Ehrman presented a man, at 45, with Bazin-Hutchinson summer eruption, which had been treated with the blue-ultra-violet rays, leaving behind deforming scar. The rays produced red vesicles which broke down.

The patient has two sisters who suffer from a similar eruption.

The Operating Theatres.

ROYAL FREE HOSPITAL.

Operation for Cataract in a Case of Senile Dementia.—Mr. Work Dodd operated on a man, at 77, who had been admitting suffering from cataract in the left eye; the patient had been mentally deficient for some years. At the hospital he was found to be very violent and noisy, requiring sometimes several attendants to maintain him in bed. About a month before his right eye had been operated upon at a special eye hospital by a colleague of Mr. Dodd’s, but after this operation the patient had torn off his bandages and rubbed the eye, which naturally became inflamed, and all hope of regaining his sight in that eye was lost. The case was transferred to the Royal Free, a general hospital, in the hope that, owing to the larger number of attendants and staff, more control could be exercised over the man. There was a fairly mature ordinary senile cataract in the left eye, and the patient was a man who, for his age, was, as far as general health was concerned, in a fairly good condition. There was no albumin nor sugar. The patient being so violent it was decided to do the operation under a general anaesthetic, and chloroform was therefore administered. The operation performed was a modification of what is known as the three millimetre operation, that is to say, the knife was inserted at a point three millimetres from the upper border of the cornea and brought out at a corresponding place on the opposite of that structure. An iridectomy was performed, and after the anterior capsule of the lens had been torn through the cataract was squeezed out by graduated gentle pressure with a tortoise-shell scoop; the pillars of the iris were restored to their proper position and the wound thoroughly cleared of all
debris. The lids were closed and a dry dressing applied, which was fastened on with collodion. The man was then carried back to the ward, still under the influence of the anaesthetic, and fifteen minims of inj. morph. (B.P.) administered. Mr. Dodd said his chief reason for operating on this eye was that he hoped the mental condition of the patient might improve, if he were restored to more intimate acquaintance with passing events through his sight being given back to him. Mr. Dodd was encouraged in this hope by other like cases on which he had operated, especially one of a man from whom he had extracted a cataract, and who, at the time, was in a lunatic asylum and blind of both eyes. On recovering his sight after the operation the mental condition of this patient became normal and he lived for several years with his family in possession of all his mental faculties. Mr. Dodd pointed out that many old people have a tendency to senile dementia, and that it is quite possible that the loss of sight might be the last straw which overbalances the already enfeebled brain. This cause being removed the subject then has more hope and interest in life, and has thus a better chance of regaining control over his actions.

The patient after the morphia injection was put into a strait-jacket; a sheet made up into a sort of rope was then looped round his axillae and fastened, to the head of the bed; the long sleeves of the jacket were attached to either side of the bed itself, so that it was quite impossible for the man to raise his hands to his eye; by these means he was more or less fixed immovably as to his shoulders and head; he was at the same time well padded with pillows. He was kept under the influence of morphia by daily injections for about four or five days, but even under the drug he was noisy and endeavoured at intervals to struggle. His back and protuberances were during all the time thoroughly looked after by the sister of the ward, and therefore there was no trouble in the direction of bed-sores or excoriations. The eye did uninterrupted well and was dressed on the fourth day after the operation and daily afterwards, the strait-waistcoat being left for seventeen days. Twenty days after operation the patient was discharged, being able with a glass to read large print; in fact, the result of the cataract operation was unusually good and rapid. The mental condition undoubtedly improved very much towards the latter part of his stay; he frequently held sensible conversations, though he still had occasional attacks of mental aberration. Considering the short time that he was under observation, the change for the better in his mental state was marked.

GREAT NORTHERN CENTRAL HOSPITAL.

OPERATION FOR MALIGNANT PUSTULE.—Mr. Acomb, house-surgeon to the hospital, operated, at Mr. Peyton Beale's suggestion, on a man, 21, 15, who had been admitted to the hospital with the following history:—
The patient, a coffee-stall keeper, was quite well about five weeks before; he then first noticed a small, reddish, itching pimple situate about midway between the angle of the jaw and the left clavicle. He thought it to be a small boil, and apparently his only discomfort was the constant itching. This sensation was so severe that he was constantly touching the place and finally "he broke the skin." In the evening he felt seedy—slight headache and chilliness, no pain in limbs. He took no further precaution beyond poulticing the "boil" with linseed until two days afterwards, when he consulted a medical man. On the next day he came to the hospital and was admitted. On examination it was found that about the angle of the lower jaw and midway between angle of the jaw and left clavicle there was a large brawny swelling which could be covered by a 3s. piece, hard and indurated around, with considerable infiltration and erythema. Situated in the middle of the broken down centre of the swelling was a black slough about the size of a shilling; surrounding this slough was a ring of "weeping" vesicles (fluid in vesicles clear with a yellow tint). There was no glandular enlargement. The tumour seemed fixed, but this was probably due to the tension on the surrounding parts caused by infiltration and oedema. It was an undoubted malignant pustule. Pulse 70 and good, temperature 99.6°. Mr. Beale, having been informed as to the man's condition, suggested that Mr. Acomb should operate at once. This he did as follows:—

Pustule excised down to and including some fibres of the left sterno-mastoid, through an elliptical incision some three inches long. A margin of 1 inch of healthy skin was excised with the tumour. Parts extremely vascular. Wound swabbed with pure carbolic, a drain inserted and wound closed with silkworm-gut sutures. On the day following, the patient was quite cheerful, pulse 64, temperature 99.4°. Seven days afterwards he was quite himself again, temperature and pulse normal, wound healthy, only a very small amount of induration being present. He was discharged cured on the following day.

A section of tissue was cut and showed numerous anthrax bacilli. The slide was exhibited at a meeting of the North London Medical Society.

It was pointed out as of interest to note that on the morning from which his symptoms dated the patient slept for an hour or so on some straw in a stable, but beyond this there was no evidence to show how he became infected with anthrax.

Mr. Beale remarked that malignant pustule was a condition very rarely seen in London, except in the neighbourhood of the docks. He had only seen one other case during the last thirteen years, that was to say, only one which was definite. Mr. Acomb, who had been a house surgeon at Leeds, had seen six or seven cases. It had been stated lately that these cases did well without operation, which meant that if the patient was still alive at the expiration of eight or ten days after the formation of the pustule, the probability was that he would recover without operative interference, the pustule scabbing over and drying up. He thought, however, that it must be a far safer proceeding to attempt to excise freely the pustule itself directly it is seen, observation, and before the constitutional symptoms, which usually came on with great severity about the fourth day, had developed to any extent. On the other hand, if grave constitutional symptoms had already manifested themselves, he could not think that excision of the pustule could in any way prolong life, so that it would appear that there were two classes of cases, those in which a general infection occurred rapidly, and those in which the infection remained localised and did not involve, at any rate rapidly, the system.

Society of Members of the Royal College of Surgeons of England.

The annual general meeting and dinner of this society was held at the Frascati Restaurant on November 10th. Mr. Joseph Smyth, M.R.C.S., was re-elected President; Dr. Danford Thomas, Dr. Thomas Morton, and Dr. Herbert Snow, Vice-Presidents; Dr. Brindley James, Honorary Treasurer; and Dr. W. G. Dickson, Honorary Secretary. The finances of the Society were reported to be in a satisfactory condition, and a substantial balance was in hand. The membership of the Society had much increased of late years, and through its agency the report of the College Council was now circulated annually to over 3,000 members.
THE ANTI-VIVISECTIONIST ON TRIAL—
BAYLISS VERSUS COLERIDGE.

The anti-vivisectionist and his methods, as set forward in the person of their arch-protagonist, Mr. Stephen Coleridge, have been tried in the balance and found wanting. Not many months ago, at a crowded meeting of the National Anti-vivisectionist Society in St. James's Hall, London, that gentleman announced that he had evidence of eye-witnesses to certain illegal acts committed at University College. The outcome of that public statement was an action brought by Dr. W. M. Bayliss, Assistant Professor of Physiology at the above-named institution, to recover damages for slander and libel on the part of the Hon. Stephen Coleridge. The specific charge was that the defendant had imputed that the plaintiff had been guilty of cruelty to a dog, and had vivisected it withoutproperly anaesthetising it as required by the Vivisection Act. The defendant pleaded justification and fair comment. His justification was the evidence of two tainted witnesses, two Swedish girls who had joined the classes at University College, and who were simply novices and unskilled observers from a scientific point of view, besides being notorious anti-vivisectionist partisans. "Fair comment" appears to be, in Mr. Coleridge's mind, on the strength of such evidence, to impute not only abominable cruelty, but also the commission of an illegal act by the evasion of the conditions imposed by the Vivisection Act. Mr. Coleridge admitted in court that he trusted solely to the statements made by the Swedish girls, and that he took no steps to ascertain from Dr. Bayliss the truth otherwise of their evidence. That fact alone stamps with an indelible brand the nature and methods of Mr. Coleridge's campaign. For his purpose, any evidence, any reckless assertion, any false argument, any bitter public imputation of evil motive, in short, any weapon whatever, no matter how unfair or how falsely it be used, is good enough to support his own particular views. His two lady wit-nesses, untrained in medical matters, see a dog struggling under an anesthetic and straightway swear that its struggles were "purposive"—the dog "arched its back and jerked its legs." The move-ments were, as a matter of fact, similar to those invariably made by any human being who takes an anesthetic, but of which he knows nothing after regaining consciousness. It is inconceivable that any person who had been in the habit of seeing chloroform administered, or who had the slightest knowledge of the subject, either in theory or in practice, could have fallen into so ludicrous and childish an error as to suspect a chloroformed dog of making "purposive" struggles. In court the plaintiff had not the least difficulty in proving that the animal was properly anaesthetised, and the movements of an ordinary reflex and uncon-scious nature. Mr. Coleridge, however, preferred the sentimental and untrained conclusions of his Swedish witnesses, whose impartiality may be gauged by the fact that they sat down and wrote an account of what they had seen at University College in a book under the catch-penny title of "Shambles of Science." That a learned lawyer should make grave public charges on such hopelessly tainted evidence would be incredible were not one already acquainted by long experience with the hopelessly faulty intellectual methods employed by Mr. Coleridge with regard to the question of experimental investigation. Truth is logic, and to be illogical is to be untruthful. We have again and again pointed out the illogical nature of Mr. Coleridge's arguments and conclusions. Now, for the first time, he has been called upon in a Court of Justice to satisfy the logical sense of the law as to the methods whereby he has sifted the terms and premises of his publicly-stated conclusions. He has failed to prove that his methods are logical, or, to put it in another way, that what he said was true. The special jury engaged in the trial marked their sense of his reckless conduct in publishing so false and serious a slander by assessing the damages against him in the substantial sum of £2,000. It is too much to hope that even so severe a lesson will bring Mr. Coleridge to the full possession of the realities of his position as a self-constituted critic of medical science and its methods of research. The attitude of the anti-vivisectionists generally may be to some extent inferred from an article published in the Daily News shortly after the trial. The writer might have been Mr. Coleridge himself, so stuffed is the whole effusion with logical fallacies. First of all, experimentation is called "torture," a begging of the question that stamps the writer at once as a partisan. He assumes, for purposes of argument, that man has a right to ex-periment for purposes of science as, say, for food. He makes an exception, however, in the case of the dog, because "it might almost be said to have surrendered itself into our safe-keeping." What about lambs, and calves, and horses and pigeons: how does man repay them for their trustfulness? We have no hesitation in saying that more brutality
to horses could be seen in a single walk along a
crowded London street than could be found in all
the physiological laboratories of the United King-
dom in a month. Besides, the animals in the
laboratories do not feel any pain, whereas the
horses are flogged and broken down with terrible
labour and burdens until they die. But the
Daily News prefers to tickle the sentiment of its
readers by talking about the "poor, big, brown
doggie," that is brought into the lecture-room
to be "mangled." It would be just as reasonable
to write diatribes upon the beauteous lads and
lasses who are daily taken into the operating
theatres of our hospitals to be "mangled" by the
surgeons. It is to be hoped that within the next
generation the general level of intelligence will have
advanced beyond that of the journal from which
the foregoing passages have been quoted. Then
the proposition that experiments on living animals
are necessary for teaching purposes will not
be met with such irresponsible clap-trap as
that used by the above-quoted journal in the
statement that "we are all responsible for
this hideous defiance of the laws of humanity."
Meanwhile, the verdict in the case of Bayliss v.
Coleridge may be welcomed as a vindication of
truth, reason, and sober humanity against the
aspirations of weak and misguided sentimentalism.

THE VALUE OF EPNOMYIC NOMENCLA-
TURE.

The custom of associating proper names with
diseases, physical signs, or clinical tests is one
which has long been prevalent in medical science,
and it appears to show no sign of falling into
disuse. From the student's point of view many
objections have been taken to the practice, which
seem at first sight to be plausible, on the ground
that it burdens the memory needlessly with a
useless mass of names. It is argued that it is the
disease itself which should be studied rather than
any particular individual, be he never so illustrious,
with whom it is connected. This is, of course, true
in the main, but it was never intended that medical
biography should enter seriously into the student's
already over-full curriculum. Dr. George L.
Richards, in his Presidential Address delivered
before the Section of Laryngology and Otology at the
last meeting of the American Medical Associa-
tion, strongly deprecates this eponymic tendency,
especially when used to distinguish certain opera-
tions, and pleads for a more anatomical descrip-
tion. A little reflection, however, will show that
this tacking on of proper names, far from being a
hindrance to the student, has a definite mnemonic
value, for by the adjectival use of the surname a
new and concise term is formed by which a great
deal of unnecessary circumlocution is avoided.
How much easier, for instance, is it to speak of a
patient as possessing "Romberg's sign" than to
waste words in saying that is "unable to stand
steadily with his feet together and his eyes shut"?
Though we cannot yet say that there are no more
diseases to discover, yet the number of new and
distinct clinical entities which are added to our list
eyear by year are, from the very nature of things,
made up of such a complexity of symptoms that
here again we are glad to say that a patient is
affected with "Banti's disease," rather than that
he is suffering from "a chronic intoxication with
anaemia accompanied by chronic endophlebitis of
the spleen, jaundice, and hepatic cirrhosis." Some
mental effort is, doubtless, necessary in order to
associate a given proper name with a long string
of symptoms and pathological changes, but the
whole training of the medical man has enabled
him to go through this process of "mental asso-
ciation," with comparative ease. Other sciences,
also, besides medicine, yield a variety of eponyms,
al of which possess a certain value to their respect-
ive students. There is another use for eponymic
omenclature which members of an ancient and
learned profession will not be slow to appreciate.
We refer to the honouring of a great master of
medicine or surgery in handing his name down to
posterity by associating it with some disease,
physical sign, symptom, or operation described or
devised by him. It is very unlikely that "Bright's
disease" will ever be known by any other name,
such a hold has it taken upon the medical and lay
public; yet there are those who would discard it
altogether, preferring to speak of nephritis with a
prefix designating its particular variety—when
this can be accurately determined during life.
Other names, like "Addison's disease," are so
admirably distinctive, that it would be hard to
find for them a substitute. Where the evil lies,
of course, is in rushing to the extreme and dragging
in the name of Jones or Smith—joining them, if
necessary—to every slight variation or modifica-
tion in already existing maladies or operations
which are named after this fashion. To tack on
any other name to that of Bright or Graves would
be little short of sacrilege, while in many instances
the practice only excites ridicule. Nevertheless,
we cannot help thinking that the total banishment
of eponyms would be a retrograde step and one
which would be, in the long run, distinctly
disadvantageous alike to the student and practitioner.

MODERN VIEWS OF DIPHTHERIA.

In the history of diphtheria as a disease there has
not been any startling change since the dis-
ccovery of an anti-serum and the establishment of
its value in practice. Nevertheless, year by
year our attitude with respect to certain problems
both of diagnosis and treatment, is changing, and
we have to accommodate our views to the observa-
tions and generalisations of modern observers.
In regard to the diagnosis of the disease, there
have been during the last few years many different
doctrines in vogue for limited periods. There was
the time when the diagnosis was made on purely
clinical grounds—no other, indeed, being possible.
Then, on the discovery of the diphtheria bacillus,
there was the inevitable tendency to rely almost
entirely on bacteriological examination for a
decision as to the specific nature of the disease.
With a firm faith in the infallibility of the pro-
nouncements of the bacteriologist, it is to be
feared that the physician grew somewhat careless
as to the clinical features of the case. Instead of making a provisional diagnosis pending bacteriological information, he too often made none, but waited till he received it ready-made from the laboratory. Nowadays, however, a certain proper scepticism of laboratory-made diagnoses is appearing, and, of necessity, at the same time a greater reliance on clinical conditions. Various facts have conduced to this position. The physicians have discovered that they were receiving positive reports in cases of coryza and scarlatina, as well as in health; while, on their side, the bacteriologists have found that the features on which they were in the habit of relying for purposes of distinction were insufficient, and that there are many other organisms which resemble the diphtheria bacillus in everything except pathogenicity. While it is perfectly right that main reliance should be placed on clinical features for purposes of diagnosis, yet the physician must still look for considerable help to laboratory methods. Although tests of pathogenicity are, on account of the delay involved, as well as of the heavy expense, limited in their usefulness, yet there are certain procedures by which a speedy and very useful opinion can be formed. The most important of these is the examination of a direct smear of a swab from the throat. With the help of Neisser’s distinctive stain, diphtheria bacilli can nearly always be recognised if present, and there is less confusion from other organisms than when cultures have been made. It is satisfactory, however, whatever be the difficulties of diagnosis, that the treatment of the disease is well established. Not only is the value of antitoxin so far above question as to render its omission a crime, but its harmlessness in all conditions is so certain that a doubtful diagnosis is of much less grave import than it would otherwise be. In all cases of doubt it is not only a wise rule, but an imperative, to administer antitoxin. As to the methods of administration and the dosage, there is some change in the body of current opinion. The tendency is to increase the dose of antitoxin in severe cases far above what was formerly the custom, and further to hasten its action by injecting it intravenously rather than subcutaneously. It is curious that in these countries the operation of intubation is still in disfavour compared with tracheotomy, since its results in hospital treatment elsewhere are so encouraging. Whatever its relative disadvantages in private practice, there is little doubt that in hospitals they are outweighed. In the pathology of the disease, also, we have some new facts. The most important of these is the proof that in severe diphtheria there is an actual bacteriæmia. Following from this we find that lavage of the blood by large saline injections is gaining ground as a mode of treatment. In reference to the bacteriæmia, too, it has been pointed out that in nearly half the deaths from diphtheria there is found to be thrombosis in the heart. There can be little doubt that many of the sudden deaths we were in the habit of vaguely explaining as due to toxic action on the heart muscle are, in fact, due to thrombosis.

Notes on Current Topics.

The Edalji Petition.

The petition to the Home Secretary has been widely signed by members of the medical profession. Amongst the signatures are those of Dr. G. H. Savage, Professor Clouston, of Edinburgh, Dr. F. J. Waldo, Dr. F. J. Smith, Dr. Ward Cousins, Dr. H. Jellett, and Mr. E. H. Tweedy. In order to prevent misunderstanding it may be stated that this petition is simply for an inquiry into the state of mind of the prisoner Edalji. If he committed the crime of which he was convicted, namely, the purposeless maiming of a number of cattle, then he must be fitted rather for a lunatic asylum than for a convict prison. That is a purely medical issue, and as such is approached by a petition to the Home Secretary for a formal inquiry into the state of mind of Edalji. We shall be glad to receive any further signatures within the next few days, and also to forward forms for any medical men who may wish to add their names.

Auto-Tattooing of the Buccal Mucous Membrane in Plumbism.

The presence of the well-known “blue line” on the gums is one of the first things the physician seeks when he is investigating a case of the symptoms of which suggest chronic lead-poisoning. At a recent meeting of the Société Médicale des Hôpitaux, MM. Caussade and Montés exhibited two patients who not only showed this feature, but also presented a much rarer manifestation in the shape of tattooed-looking plaques on the mucous membrane of the cheeks. These peculiar lesions were well described by Gubler, in 1868, as slate-coloured patches resembling the spots seen upon hunting-dogs. Both patients were males, workers in colours, and had suffered from other symptoms of plumbism, such as colic. This “tatouage saturnin” appeared in the form of large, slaty-grey plaques, having a somewhat star-shaped or whorled arrangement, composed of an aggregation of minute points, and were situated on the inner side of the buccal mucous membrane. Where the teeth were deficient no pigmentation was visible, and it was observed that the patches corresponded accurately to the position of the teeth, the sharp notches of which were traced, as it were, in a metallic pattern upon the cheek. The condition was, therefore, plainly one of auto-tattooing or inoculation of the sulphide of lead clinging about the gingival borders directly into the adjacent mucous membrane. The authors consider that these plaques are an evidence of a grave intoxication of the system with lead, so that they would possess a distinct prognostic value. They are also said to occur with much greater frequency than is generally believed.

Diet and Physical Deterioration.

The factors that induce physical degeneration are so many and various that not the least part of the work of the Physical Deterioration Commission will be that of classifying and arranging.
them into something like a comprehensive and systematic order. Directly after birth there are influences at work which may make or mar the future physical prosperity of the infant. Later, the process of education, the habits of daily life, the hygienic, mental, and moral surroundings, the struggle for existence, and the stress of competition all leave their mark for good or for evil upon every individual. But through and above all the question of suitable and sufficient diet becomes one of paramount importance. The life of the infant may be endangered or even sacrificed by improper feeding and unwholesome food. The digestive powers of the young and vigorous may be so sorely tried by reason of the rush and hurry of modern life that in after years they become continual martyrs to dyspepsia. Excess in eating, especially of certain kinds of food, is a fruitful cause of suffering of another kind. From the figures quoted by Major Craigie in his recent presidential address to the Royal Statistical Society, there seems to be no doubt that we, as a nation, habitually consume far too much animal food. This applies, of course, more particularly to the upper and middle classes, who are accustomed to partake of meat three and sometimes four times a day. As compared with 1859, it is seen that the quantity of meat consumed in this country is nearly four times as much per head of the population. The penalty paid for this excess will probably be found in gout and all the evils dependent upon it, chief among which are arteriosclerosis and granular kidney. The popular idea that flesh-foods increase the animal spirits has some foundation in fact, for dyspepsia caused through overloading of the stomach commonly leads to neurasthenic manifestations. On the other hand, a deficiency of meat is a fruitful cause of anaemia and associated disorders, which are, naturally, more predominant among the poorer classes. It is also pointed out that tea-drinking and cigarette smoking are largely in excess of what they were seventy years ago. These latter act more directly upon the nervous system, and, therefore, tend to produce less stable and resistant mental organisations, which are unable to bear increased strain. As the burning-power of a fire is measured by the quality and quantity of the coal it consumes, so it will be seen that there is more than a casual connection between the diet of the individual and his physical condition. We hope that the matter will receive at the hands of the Commission all the consideration which it deserves.

A Minister of Public Health.

Persons with a cause at heart, which they wish to see pushed forward at a greater pace than the conservative instincts of the community allow, are apt to think that an extra Cabinet Minister, charged to carry out their ideas, would cleave his way through the difficulties that obsess their path. Merchants d’âme for a Minister of Commerce; hygienists for a Minister of Public Health. At almost every gathering of medical officers of health and sanitary officers a resolution is passed calling for such an official. It is certain that a great deal more public attention to matters bearing on health will have to be aroused before such a proposal is likely to assume concrete shape, and the functions of the President of the Local Government Board be divided up between two members of the Government. Cabinets are becoming more and more unwieldy every year, and the addition of another Minister or two would only add to the evil—already great enough—of divided responsibility. The enthusiasts who want a Public Health Minister and a general public health service for the whole country are oblivious of the fact that legislation is tending to take quite the opposite course to the one they desire—namely, towards devolution as opposed to centralisation. It may comfort them to know that that go-ahead little colony, New Zealand, has lately created a Ministry of Public Health, but then New Zealand has not centuries of tradition behind her, and she likes experiments. One would wish that the dream might be realised for this country, but it is no good disregarding patent facts, which all go to show that efforts to raise the health of the nation must be primarily directed at the local authorities, and not at the central Government.

"Rural Hygiene."

A third edition of Dr. Poore’s “Rural Hygiene” serves as a reminder that there is plenty of life still in the common-sense theories and practical methods of its author. To write popularly on such unromantic subjects as the supply of water and the disposal of excreta argues a rare gift, and the book is worth reading if only to enjoy the masterly use that Dr. Poore makes of irony and satire. Soon after the first edition had appeared in 1893 it was said in one of the society journals that every other girl whom one met at a country house was deep either in Sarah Grand’s “Heavenly Twins” (then in its first blush of popularity) or in Poore’s “Rural Hygiene.” There can be little doubt as to which proved the most profitable, for though Dr. Poore’s ideal may be Utopian, there is much that may well give food for mature reflection, and the tendency of some of the recent advances in the science of public health has certainly been to confirm his contentions. These are conservative in the best sense. Everything has its use and nothing should be wasted; excreta should be employed to enrich the earth, not to pollute the air; corpses should not be sunk into clay to putrefy, but covered with earth to nutrify. Fresh air and clean water are eloquently pleaded for, and scorn is heaped on the favourite “schemes” of sanitary authorities. To the orthodox Dr. Poore’s ideas have always been a source of amused contempt, but could they all be carried into practice life would be much cheaper, healthier, and happier.

Diarrhoea and Polluted Water.

It is so seldom that an epidemic of diarrhoea can be demonstrated to have been due to the fouling of a particular source of water supply
that considerable interest attaches to the report of Dr. Thresh on the outbreak of diarrhoea that recently affected Chelmford and the neighbouring district. On July 25th a large number of persons were suddenly seized with diarrhoea, and before August 23rd no less than 1,400 people had suffered similarly, fourteen of them fatally. All ages and classes were affected, but the mortality fell chiefly on young children. As attention was directed to the outbreak it was found that the patients were confined to one part of the borough of Chelmsford and to a neighbouring village. The water supplying these areas was derived from mains which conducted it from a small uncovered reservoir, into which water was pumped from a deep well. This reservoir was not bricked up to the ground level, and a heavy fall of rain on July 23rd seems to have washed into it soil from a patch of garden in which it was situated. The bottom of the reservoir was shinnny with mud and teeming with worms, and two days after the water from it was cut off the cases ceased. Epidemic diarrhoea may be caused by bacterial infection, decomposition products, or the mechanical irritation of solid particles in the intestine. A good many outbreaks due to these causes have been recorded by Dr. Thresh in his book on "Water and Water Supplies." None of these, however, have been on so large a scale as the Chelmsford epidemic, and in few have the results of investigation and prompt action been so markedly demonstrated.

Thrombosis in Chronic Dysentery.
The occurrence of thrombosis in a limb as the result of a specific infectious disease, or in the course of some grave cachectic condition, is well recognised. It is concomitant with certain changes in the composition of the blood itself, and in anemic and oligemic states it would almost seem to be a protective act on the part of the organism. As a complication of chronic dysentery, however, thrombosis is very rare, and only a few cases have been recorded in the literature of that disease. Special interest, therefore, attaches to a case published by Dr. Githens, occurring in the Philadelphia Hospital under the care of Dr. Riesman. The patient was a man, aged forty years, who had suffered from a chronic form of dysentery for fifteen years, with twelve to fifteen liquid stools daily. He was anemic and considerably emaciated. One day, when lying in bed, he experienced a sudden stabbing pain in the inner side of the left thigh, and the limb speedily became swollen and tender. The saphenous vein was hard, but there was no oedema. Two days later the limb was still acutely painful, and the capillaries were intensely injected. Some petechial spots and oedema appeared. The blood showed only a slight reduction in the number of red cells. After three weeks, walking became possible. The pathology of phlebitis in dysentery is somewhat doubtful, but it appears probable that it is due to a condition of anaemia combined with some infection from the gastro-intestinal tract. The eruption of petechiae in the case quoted is a very unusual accompaniment of femoral thrombosis, and Dr. Githens has found only three other cases reported. The treatment of this troublesome complication, which, from its liability to cause embolism, is a dangerous one, consists of absolutely immobilising the affected limb and relieving pain by the local application of belladonna ointment without rubbing, assisted, if necessary, by hypodermic injections of morphia. Massage should not be commenced until at least six weeks after the onset of the attack.

The Arrest of Inebriety.
The inebriate has long been regarded as a sinner rather than a patient needing protection and direction. It is only with recent years that an enlightenment of conception has led to any improvement in practice. Even yet our means for efficient control are most meagre. Many of the institutions seeking to afford measures making for restoration are still dominated by the persistence of mediaeval methods, and it must be regretfully admitted that in not a few instances those who are responsible for the conduct of these so-called retreats are almost entirely ignorant of scientific methods and fettered and weighted by old-time traditions and effete customs. It is necessary to remember this when studying the excellent report of Dr. R. Welsh Branthewe, the inspector under the Inebriates Act. In this new Blue Book will be found much matter for careful consideration. In spite of the limitations and deficiencies in our legislation for dealing with the inebriate class, and notwithstanding the low standard of efficiency prevalent in some institutions, most encouraging results have been attained. Dr. Branthewe considers that about 38 per cent. of cases turn out well. He also contends that women are not less reformable than men. As evidence of the rapid increase of inebriety among women there is the startling note that while the number of male patients admitted to retreats has remained practically stationary the number of women entering was almost double that of the former year. Manifestly with the establishment of clear views regarding the etiology and pathology of inebriety, an extension of legislative measures will have to be secured. The Act of 1890, which requires that the consent of a habitual inebriate, who does not break the law, shall be obtained before he or she enters a retreat, is inadequate and will probably need to be strengthened before any great reduction of secret drinking can be hoped for.

Fever and Small-pox.
It is well to remind the public that small-pox is still with us, and that outbreaks are occurring at intervals over the whole of the United Kingdom. In the case of so highly infectious a malady, the presence of a multitude of potential centres of fresh mischief can hardly be regarded with complacency, especially in view of the fact that a large percentage of the population remains unprotected by vaccination. The mass of infection of all kinds in our midst is simply stupendous, and it says much for the courage of modern
sanitary science that its efforts are never for one moment relaxed in the fight against communicable maladies. The metropolis alone furnishes a small army of patients suffering from specific febrile invasions. The returns issued by the Metropolitan Asylums Board on November 20th, for instance, showed that there remained under treatment in the various hospitals belonging to the Board 2,868 patients. These were made up of 1,810 scarlet fever cases, 803 diphtheria cases, and 255 enteric cases. There were remaining under treatment 50 small-pox patients, 49 being at the Long Reach Hospital and one at the South Wharf Shelters. While there is a single small-pox patient in a London hospital, the provincial medical officers of health will have a corresponding load of anxiety.

Epistaxis in Acute Rheumatism.

The occurrence of nose-bleeding in children is generally regarded by parents as a thing of little consequence, to be treated by simple expedients, such as posture. Its significance is not always appreciated even by medical practitioners, for as a symptom it is too often apt to be looked upon as salutary, or something of the nature of a safety-valve. Like children's tears, the blood in the frail vessels of the nasal mucous membrane is very close to the surface, ready to make its appearance upon some slight local or systemic provocation. In a paper read before the Ohio State Medical Association in June, Dr. Friedlander, of the Jewish Hospital, Cincinnati, calls attention to the fact that idiopathic nose-bleeding may be one of the earliest manifestations of acute rheumatism in childhood. When no local cause can be found to account for this symptom its occurrence is to be regarded with some suspicion. More recently, Dr. H. G. Langwill, (a) of the Leith Hospital, Edinburgh, records three cases in which epistaxis was seen in direct connection with the onset of acute rheumatism, one case having had it at the beginning of three separate attacks. The disease as it affects children is notoriously protean in its manifestations, while many of the symptoms are altogether latent. It not infrequently happens that grave cardiac mischief supervenes before the true nature of the illness has been recognised. In the adult, the malady is generally more straightforward, but it has been observed that epistaxis may occur with the onset of acute rheumatism, even when the age of childhood has passed. The connection of this symptom with granular kidney is more widely known. Since the early signs of the disease in the child are vague, any sign, such as epistaxis, which has been proved to have even an indirect connection with it will be welcomed as being likely to possess some diagnostic value.

Artificial Fertilisation of Mammals.

From the earliest times the artificial fertilisation of phanerogamous plants has been in vogue, and from time to time the artificial fecundation of mammals practised, sometimes successfully and some-

times not. In modern times Brown-Séquard and Marion Sims conducted experiments on mammals. The question attracted the attention of Dr. Ivanoff, who has for some considerable time past been experimenting (Vratch) on guinea-pigs, dogs and rabbits, and more recently on sheep, cows, and horses, with semen preserved in a saline solution, entirely free from the prostatic secretion and all other products of the accessory glands. The practical results of his researches have already been adopted to some extent in stock-raising in Russia, and so successful has he been that every one of his experiments on horses in 1901 turned out successfully. Remarkable results have been obtained in this way in cross-breeding and the production of hybrids. In the simplicity of the methods of procedure he resembles Lazaro Spallanzani, whose researches on reproduction are almost as much forgotten as his controversy with Buffon. Experimenting on the same lines Ivanoff has advanced our knowledge considerably, especially on the subject of hybrids, and has demonstrated the accuracy of the views enunciated at Padua by Spallanzani.

The Homicidal Hat-pin.

Feminine fancy has ordained that the skewer-like hat-pin is an essential element of cephalic attire, and must be retained. It is an instrument with potential energy for endless damage. Numerous accidents, some of which have proved fatal, have resulted from a persistence in the practice of hat-fixing by this convenient but dangerous article. A return to attachment by elastic may not arouse aesthetic enthusiasm, but certainly it is time the wit of womankind was turned to the inventing of some means by which the offending hat-pin was robbed of its homicidal tendencies, or the refractory hat might be retained by safety-pins or other guileless means. Unless a woman will look to this matter mere men will have to intervene, if only in his own interests and as a means of self-protection. Possibly the plan of licensing might be followed with advantage. Just as a man may not carry a revolver without a license, so a woman may not carry that hardly less deadly weapon, a hat-pin, without a yearly license purchased from the State.

The Radical Cure of Epilepsy.

In spite of the many therapeutic remedies that frequently cure, and almost always modify, epilepsy, cases occur in which the disease is not amenable to treatment with drugs, and call for the interference of the surgeon. In one such case recently reported by Jonnesco, the disease was cured, that is, the epileptic attacks ceased and the patient, a young woman, went about for some months as usual. The operation performed by Jonnesco, which was followed by such good results, calls for description. His preliminary incision was only 7 cm. in length, and was parallel to the posterior border of the sterno-cleido muscle. It was completed without cutting the external jugular vein. When the sterno-cleido muscle was

(a) Scottish Medical and Surgical Journal, November, 1900.
exposed he tunnelled under it with his index finger until he felt the trunk of the sympathetic nerve. He excised with a blunt-pointed curved pair of scissors the three cervical ganglia and the first thoracic. In each case he isolated the ganglion between two catch-forces before excision. The operation was almost bloodless and was quickly followed by relief. We acknowledge that the dexterity of M. Jonnesco is equal to the task of operating with such a limited incision successfully; but we think that, as a rule, the incision for the removal of the four ganglia should be much longer.

Cured Without Drugs.
All medical men know that the treatment of chronic constipation with drugs is unsatisfactory. It is very often entirely unsuccessful, and even at its best it but substitutes one evil for another. It may cure the symptom, mere coprostasis, but it has no effect on the anatomical or physiological condition which is at its root. In many cases the cause is local, as, for instance, when constipation follows on piles, fissures or strictures of the anus or rectum, and local treatment is then required. In other cases the constipation may be traced to improper diet, irregular habits, insufficient exercise, or lack of tone in the abdominal and intestinal muscles. Careful inquiry should always be made as to the ultimate cause, and measures of relief adopted in relation thereto. It will be found that in most cases successful results can be obtained without resort to a habit of continuous drugging. Dr. Gant, of New York, who for many years has not made use of medicines in treatment of chronic constipation, enumerates in an interesting paper (a) some of the methods he has found of use. These vary in nature and severity according to the nature of the case, from the simple drinking of cold water to the divulsion of Houston's valves, or even of the sphincter muscle. As a substitute, when abdominal massage is unattainable, he recommends that the patient himself, while lying down, should roll a heavy cloth-covered ball over the course of the colon. Though one may not agree with all Dr. Gant's suggestions, it cannot be too strongly impressed that medicinal treatment of chronic constipation is only a makeshift or a last resort.

Cancer of the Lung.
One of the least common of diseases is cancer of the lung, and, we may add, one of the most difficult of recognition. It is seldom treated of in manuals of medicine, and even the voluminous works of these modern days do little more than mention it. Withal, it is worthy of study in that when present it simulates pleuro-pneumonic infection, for which it is too often mistaken. From some cases published by Musser we infer that the pathogenic sign of the disease is the presence of a nodule in the lung, which may or may not be found by exploration. The sputum revealed nothing; a short time before death the lymphatics

became involved and cachexia appeared. The amount of the expectoration is very variable in different patients, in some, scarcity in amount is present throughout the disease, and in others it is abundant. In one case the fluid welled up from the pharynx and oesophagus in such quantities that it was calculated that three pints daily were expelled. Of course there is comparatively little trouble in recognising secondary carcinoma of the lung when it occurs; nevertheless, the physician might, in some cases in which the infection of the lung occurs early in the disease, mistake the disease as pleuro-pneumonia occurring as a complication of the disease.

Anti-Cancerous Serum.
At a recent meeting of the French Surgical Society, M. Doyen brought under notice a serum which he described as anti-cancerous serum. This serum was tried on eighty cases of cancer, in forty-eight of which it gave no results, the treatment having been commenced either too late or not continued long enough to produce, according to M. Doyen, good effects. In the remaining thirty-two cases the results were satisfactory. Unfortunately, no information of the source or mode of preparation of the serum has been given. We hope, however, that M. Doyen will make known the nature and mode of preparation of his remedy.

The Society of Apothecaries engages both sympathy and attention, not less on account of its ancient traditions than of the activity it has displayed of recent years. The value of the diploma granted by the Society has multiplied a hundred fold from the scientific point of view, and has for some time past become a token of solid training and achievement. In past times the Society has had to hold its own against powerful rival bodies, but its record of late years has happily been one of continuous progress. Under these circumstances we are glad to hear that the associated physicians and surgeons of the Society of Apothecaries have called a conjoint meeting of the Apothecaries' Halls of London and of Ireland, to be held at the Blackfriars Hall, on December 1st next, at 4.30 p.m.

Personal.
A portrait has been presented to Dr. D. H. Starling, of Aberdeen, by the Perthshire branch of the British Medical Association on the occasion of his jubilee.

Mr. Thomas W. Cutler, F.R.I.B.A., has been elected Treasurer to the Sanitary Institute, to succeed the late Professor W. H. Corfield, M.A., M.D.Oxon., F.R.C.P.

The Bradshaw lecture before the Royal College of Surgeons of England will be delivered on Wednesday, December 9th, at 5 p.m., by Mr. Henry Morris, who has chosen for his subject "Cancer and its Origin."

Sir Hermann Weber will deliver a lecture on Thursday, December 3rd, at 5 p.m., at the Royal College of Physicians of London, "On the Means for the Prolongation of Life."

(a) Medical Record, October 24th.
SPECIAL CORRESPONDENCE.

THE MEDICAL PRESS. 599

NOV. 25, 1903.

DR. F. PARKES WEBER and DR. T. N. KELNACK have been appointed full Physicians on the staff of the Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood.

MR. T. H. OPENSHAW, F.R.C.S., C.M.G., surgeon to the London Hospital, has been appointed by the Metropolitan Asylums Board honorary consulting surgeon to the training ship Esnouh at Grays.

DEPUTY-INSPECTOR-GENERAL of Hospitals and Fleets Edward Elphinstone Mahon, C.B., has been promoted to the Inspectorship of the Hospitals and Fleets in His Majesty's Fleet (dated October 10th, 1903)

DR. ALLAN MACFADYEN will deliver a lecture at the Lister Institute of Preventive Medicine, Chelsea Gardens, London, S.W., on Thursday, December 3rd, at 9 p.m., on "Intracellular Bacterial Toxins and their Practical Application."

The Public Orator, Dr. Sandys, delivered a more than usually interesting Latin oration on the recent occasion of presenting for the complete degree of Master of Arts honoris causus Mr. Howard Marsh, the newly elected Professor of Surgery.

SIR HENRY BURDETT will open a discussion on "London Hospitals and Medical Schools and Their Sites" at a meeting of the Hospitals Association on Thursday, December 3rd, at 4.30, in the board-room of Charing-cross Hospital. Mr. Thomas Bryant will take the chair.

SIR ANDERSON Crichtett and Mr. Malcolm Morris have retired from the respective posts of Ophthalmic Surgeon and Dermatologist at St. Mary's Hospital, London, after twenty years' service in those capacities. An account of the presentation of testimonials will be found in another column.

Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENTS.]

SCOTLAND.

SMALL-POX IN GLASGOW.—There were forty patients last week in Belvidere Hospital suffering from small-pox. Dr. Chalmers, the medical officer of health, emphasises the necessity of medical practitioners exercising the utmost care in diagnosing cases, many of the present cases being of such a mild type as to be readily overlooked unless the greatest care is taken. The antivaccinators have just held their annual conference in the Christian Institute, Glasgow. It is said there was a large attendance of representatives from all parts of the country. One gentleman urged that it was necessary to resist vaccination by every means in their power, and that it should be made a test question at all elections. The president of the Conference read a paper on vaccination and cancer. The general conclusion reached was that vaccination, especially when performed with care and skill, is capable of producing cancer. With such views promulgated, it is not to be wondered at that there is always a residuum of the population who refuse to submit to re-vaccination, and hence in all likelihood the outbreak of small-pox at the present time. The problem is how to get at this recalcitrant mass.

GLASGOW SOUTHERN MEDICAL SOCIETY.—The usual fortnightly meeting of this society was held on the evening of Thursday, the 12th inst., in the committee room of the Royal Infirmary, the President, Mr. Thomas Richmond, in the chair. Dr. T. K. Monro, one of the physicians to the hospital, gave a most interesting and extremely instructive demonstration on "Some Diseases of the Spinal Cord." Patients were present, who exhibited well-marked symptoms of locomotor ataxia, hereditary ataxy (Friedreich's disease), Duchenne's paralysis, and other forms of spinal cord affections. Dr. Monro described in detail each case, explaining the columns of the cord involved in the different cases, and by means of the latest lantern of beautiful pictures—anatomical and pathological—were shown on the screen, which enabled those present to have a very clear and accurate conception of the different forms of spinal paralysis. The demonstration lasted nearly two hours, and undoubtedly proved a mulum in parvo. A very hearty vote of thanks was awarded to Dr. Monro for his admirable demonstration, and a similar vote of thanks to the managers of the Royal Infirmary and Dr. Thomson, the superintendent, for their kindness to the members of the society.

GLASGOW ROYAL INFIRMARY.—It is very gratifying to learn that the fund for the reconstruction of the infirmary, which for some time remained about £250,000, is now nearly £200,000. The estimated total was £240,000. This sum, however, will in all probability be exceeded considerably, and there is every prospect of the full sum required being realised at an early date.

BELFAST.

ULSTER MEDICAL SOCIETY.—The annual dinner of this society was held in the Medical Institute, Belfast, on Thursday evening, the 10th inst. Twenty Fellows and Members were present. After dinner the president, Dr. John Campbell, proposed the toasts of "The King" and "The Lord Lieutenant, and Prosperity to Ireland," the latter being proposed by Dr. J. R. Davison. The third toast, "The Irish Medical Association," was a new one on the list, and was introduced to give the members an opportunity of showing their sympathy with the present movement on behalf of the Poor-law Medical Service. The toast was proposed by Professor Lindsay, who, in the course of his speech, said that such an audience he was not necessary to expound the disabilities under which our patients in the Poor-law Service labored. He would not attempt to remedy the wrongs the waiting policy had been tried without success, and the time had now come for a policy of action. The programme of the Irish Medical Association was a very moderate one, and personally he thought they should aim at being made a branch of the Civil Service. The care of the public health was a matter of quite as great importance as the care of the public exchequer. Dr. Lindsay further dwelt on the increased cost of medical education and of living as reasons for reconsidering the remuneration of medical men in the public Services. He coupled the toast with the name of Dr. Kidd, the President of the Irish Medical Society, who had done so much for the voice and pen, for his brethren. Dr. Kidd, in replying, said that the association now numbered 33 branches and 900 members, an important factor in the fight, for without the sinews of war little could be accomplished. A conference could be of use; it would also be necessary to clear the public mind of some misapprehensions regarding the movement. £300 a year was often mentioned as the sum they aimed at, but this was an irreducible minimum, and barely a safeguard against modification in different circumstances. It was also necessary to contradict a statement often made, which he could only characterise as a malicious falsehood, namely, that this movement was a political affair, run by Protestants, Orange men, and Free-masons. As a matter of fact, of the nine members of Council, six were Roman Catholics, and their one wish was to keep entirely clear of religion and politics. As regards the proposal to make the Poor-law Medical Service a branch of the Civil Service, it was not sufficiently known that at the present time three-fourths of the medical officer's salary actually came from Government, so that it would not be a long step to pay the other quarter as well, and make the service a Govern-
The toast of "The Queen's College and the Belfast Medical School" was proposed by Dr. McLoughlin, of Derry, President of the Ulster Branch of the British Medical Association, and by Dr. W. C. Mackenzie, Dr. M'Harry, Dr. Leslie, Dr. McKisack, and Dr. MacIawaine, Dr. McLeish playing the accompaniments. Dr. Morrow, by special request, recited "The Country Doctor."

GOLF.—The medical golfers of Belfast, who form an important section of the profession, have heard with much satisfaction that Professor Lindsay has offered a silver challenge cup, to be competed for annually by medical men. A small committee has been appointed to draw up rules and conditions for the competition.

NEWRY UNION.—The proverbial caution of the Ulster native was well shown at a meeting of the Committee of this Union on the 16th inst., when the invitation of the Ballinsloe Union to meet in conference in Dublin to discuss their medical officers' salaries, &c., came up for consideration. The Clerk said that they had no trouble with the medical officers in the Newry Union. Mr. O'Callaghan: "But we do not know when we might have it, and it is too late to sharpen the sword when the drum beats for battle." Mr. McQuaid: "It is time enough to bid the 'Old Fellow' good-morrow when we meet him." Finally it was resolved to appoint two representatives.

Correspondence.

"TREPANATION IN CORNWALL."

To the Editor of The Medical Press and Circular, Sir,—It is stated in Dr. Robert Reduth's work, "Trepansion in Cornwall" (British Medical Journal; 1874), cited in the Revue d'Anthrop., 1886, pp. 648-657, that even to-day trepanation of skulls is an honour among the miners of Cornwall, England. May I ask of your kindness to inform me whether this belief has any connection with ancient trepanation of prehistoric skulls, found in round burrows of paleolithic man, in various parts of Great Britain? Could you put me in communication with a surgeon of Cornwall who is interested in the subject of prehistoric races of Ireland and Scotland, or Kymri and Celts of France?

I am, Sir, yours truly,

Albert S. Ashmead, M.D.

New York, November 5th, 1903.

(Perhaps some of our readers may be able to give Dr. Ashmead the desired information, which suggests a field of considerable interest. In America, Dr. Ashmead has, we believe, made many valuable observations upon the remains of Aztecs and other ancient or prehistoric races from the medical point of view. He has, for instance, by the application of the Röntgen rays, negatived the theory that a pre-Columbian syphilis and not leprous was the cause of certain bone changes found in Peruvian mummies.—Ed.)

Obituary.

SIR ROBERT MARTIN CRAVEN, J.P., F.R.C.S.E.

With much regret we announce the death of Sir Robert Craven, at the age of 79, which occurred at his residence in Hull on Sunday, November 15th. He springs from a family that for three generations has been famous as medical practitioners in Yorkshire, and has been also associated with the Hull Royal Infirmary. Sir Robert was born in Hull in 1824, and was the eldest son of the late Robert Craven, F.R.C.S., of Hull. His professional studies were commenced at the Hull Royal Infirmary and at the Hull Medical School, and he then entered St. Bartholomew's Hospital, London. He studied also in Paris, and in 1846 he became a M.R.C.S.E., and in the following year L.S.A. Two years later he went into partnership with his father in Hull, and in 1872 he was elected Honorary Surgeon to the Royal Infirmary there. He became F.R.C.S.Edin. in 1879, and was elected F.R.C.S.E. in 1886. On more than one occasion he was President of the East Riding and the North Lincolnshire Branch of the British Medical Association, and of the Hull Medical and Ethical Society. As a Lecturer on Anatomy and Physiology at the Hull Medical School, where he held office for nearly twenty years, he was greatly appreciated. After being forty years Honorary Surgeon to the Infirmary he was elected Consulting Surgeon, and retained this position until the time of his death. A ward was doctored to his name in the infirmary, in recognition of the services of himself and his family to that Institution.

MISS LUCY ELIZABETH CRADOCK, L.R.C.P.I., L.M.

The death is announced of Miss Lucy Elizabeth Cradock, L.R.C.P.I., L.M., at Liverpool, on November 24th, in the 71st year of her age. Miss Cradock was born in Northumberland—her father, a clergyman, was first in the Indian Civil Service, but later took the degree of M.D.Edin.—Miss Cradock was educated at Queen’s College, London, by her parents, who were then being apprenticed to Dr. Plowright, of King’s Lynn. After the usual course of study at the London School of Medicine for Women, she obtained the diploma of L.R.C.P.I. in 1883. She held the post of house physician to the New Hospital for Women, London, and in 1885 was appointed by the late Mr. Fawcett, then Postmaster-General, medical officer to the female staff of the Liverpool Post Office. Miss Cradock was one of the pioneers in the female medical movement. Her loss will be felt by a wide circle of friends and patients.

MR. CHARLES HENRY RUSSELL, M.R.C.S., L.R.C.P.

We regret to announce the death of Mr. Charles H. Russell, M.R.C.S., L.R.C.P., Medical Officer of Health for the Urban and Port Sanitary Authorities of Yarmouth. Dr. Russell was appointed to the post on November 24th, 1899. He also engaged in the activity of medical superintendent of the Great Yarmouth Isolation Hospital. The deceased gentleman had been most assiduous and energetic in dealing with all sanitary matters, and had been the means of effecting a number of improvements. He was engaged in his professional work up to the recent period as October 31st. His death is reported as due to a species of blood-poisoning, caused through a scratch from a hot-water bottle. He was a native of Southampt and, leaves a widow and three children, and was universally respected by his fellow townsfolk in Great Yarmouth.

Medico-Legal Intelligence.

A REMARKABLE LUNACY CASE—Hutchinson & Walsh, M.B., and Meehan, M.B.

The case of Hutchinson & Walsh and Another, which was heard in Dublin before the Lord Chief Baron on the 9th-12th inst., presents certain features which ought not to be allowed to pass unnoticed.

The plaintiff, a young man of 30, sought to recover damages from his brother, Walsh and a Dr. Walsh, and a Dr. Meenan, for conspiracy to detain him unlawfully.

The facts as sworn to were as follows. The plaintiff is stated to have been a quiet, sohtry and somewhat sulene young man, and addicted to secret studies. He occasionally had been heard singing and making a noise at night. On February 28th, 1901, after he had taken a couple of glasses of spirits, he became violent and abusive, and it is said suicidal, so that it was considered necessary to bind him. Next day he was
taken by the parish priest to the House of St. John of God, an asylum maintained by a religious community at Stillorgan, near Dublin. Previous to leaving home, Dr. Walsh asked Dr. Meehan to give some sort of certificate, saying that he could not give a certificate himself. The patient's relative, Dr. Meehan said, was not acquainted with the statutory form of certificate, but on this occasion he did not see the patient, and merely wrote a letter stating that the man was suffering from temporary derangement. Both doctors said that they thought the institution was in a private home, not a public asylum. On Dr. Meehan's letter, plaintiff was admitted into the House of St. John of God on March 1st, '91, and one of the community wrote out a certificate in statutory form in Dr. Meehan's name (a copy of which was sent to the Government Inspectors), this form stating that Dr. Meehan had personally examined the patient. Another certificate was procured on March 2nd, from Dr. G. R. Armstrong, and on these two certificates the plaintiff was detained until April 1st, '91, when, being ill with influenza, he became a voluntary boarder, remaining as such until discharged on April 17th, '91. The resident medical officer of the House of St. John of God, Dr. O'Connor, stated that the plaintiff was sane on March 15th and probably earlier. The Government Inspector, who saw him about the same time, had stated that he must be discharged. Dr. O'Connor also wrote that he could not rely on certificates from medical practitioners of opinion by doctors had been carried out at the House of St. John of God "a few times" to his knowledge. He declared all responsibility for this, and for the discharge of the patient when recovered, on the ground that he was not medical superintendent, but only resident physician, and stated that it was no one's duty to discharge the man when sane.

The Lord Chief Baron in his charge said that there was no proof that the unfortunate plaintiff was illegally imprisoned, but that the act of wrongfully imprisoning him was that of those who represented the institution of St. John of God, and not the act of any other person in point of law. There was no evidence of conspiracy to go before the jury, who were merely to decide whether on February 28th, '91, the plaintiff was of unsound mind and dangerous to himself and others; if so, was Dr. Walsh's treatment of him on that day reasonably necessary?

The jury disagreed. We are debarred from comment at present, as further legal proceedings are to be taken.

**Literature.**

**THE DISEASES OF THE MOUTH AND TEETH. (a)**

Although the entire lack of illustrations renders the explanations and instructions in this book difficult to follow, it is, on the whole, so far as it goes—and this is not very far—clearly written and arranged. A considerable number of "queer slips" are, however, prominent to casual observation; as, for example, on pages 1 and 2, where the age of puberty is given as the twenty-fifth year. The book displays a knowledge of the subject such as any dentist who had devoted a little special study to it might easily acquire. Great part of the subject is, however, quite outside the scope of dental surgery. Neither the complete diagnosis nor the treatment of diseases of the antrum fall within the province of a dental surgeon. If in any case he suspect or diagnose disease of the antrum, which he ought to be able to do, his duty ends in directing the patient to the fact, and referring the case to a surgeon. In treatment, the dentist's share lies in extracting diseased teeth, and, in cooperation with the surgeon, in perforating the antrum. A treatment of that subject, when these measures are called for. It is not likely that Mr. Lavan's experience has extended beyond these limits. If it did it could be only by immoral encroachment on surgical practice, which Mr. Lavan is, perhaps, incapable of. His book throughout suggests, perhaps necessarily, that it is rather a compilation than the outcome of original knowledge derived from practice. The dentist's share in treatment of symptoms of the antrum hardly calls for a separate treatise, especially as it is discussed in works on dental surgery; but the subject, which alone falls within the author's province, is, to be of any use to the dentist or surgeon. The substance of the rest of the book is to be found most fully and clearly expounded in works on general and special anatomy. No doubt we think that Mr. Lavan's work is needed, or likely to be in demand by any class of reader.

**SYPHONAGE AND HYDRAULIC PRESSURE IN THE LARGE INTESTINE. (a)**

In this brochure the author has offered to the scientific world the benefits of the light of the special revelation which he believes has been given to him regarding the functions of the large intestine in the domain of human physiology. The difficulties, hitherto, not satisfactorily explained, connected with the presence and position of the cecum and colon, the troublesome (and in many cases, lucrative) appendix—have usually been slurred over by surgeons and even physiologists. The missing key has, happily, been at last discovered by Dr. Leftwich. Its wondrous utility is the syphonage and the hydraulic pressure which influence the contents of the large intestine as a whole. The tonic contraction of the longitudinal bands of muscular fibres maintain the walls in the physical status in which those special forces are most satisfactorily utilizable. He points out, with justice, that in modern times but little attention has been given to "generalisation and co-ordination of observation bearing upon the science and practice of medicine." And we are informed that "it is the author's hope that he has made a modest advance in this direction. There may be a difference of opinion regarding the applicability of the term "modest"; but the subject is one which deserves consideration, and should be studied by all in these appendicular days.

**JELLET'T'S MIDWIFERY. (b)**

"It is not an exaggeration to say that the most essential knowledge in midwifery is the knowledge of anatomy." This is the sentence with which the new edition commences, and it forms the key-note to the entire work. The author counsels against over-seaful ante-partum and post-partum douching, and even advises against smear ing the fingers with a lubricant before making a vaginal examination. We quite agree with him. There is at the present time far too much interference with normal labour among certain sections of the profession. Meddlersome interference must always be avoided as it is certainly fraught with danger; we are accordingly pleased to note that the practice carried out at the Rotunda Hospital accords with our own views on this all-important subject. The chapter on the management of normal labour forms a model. Support of the perineum during the birth of the head is not recommended. Another mode of preventing perineal laceration is stated, and consists in pushing the head forward by applying the heel of the right hand between the anus and tip of the coccyx, while the fingers of the left hand endeavour to draw the head forwards. Jellett insists on the necessity of first thoroughly preparing the vagina and the birth canal. The use of douching and the application of cold water is carefully discussed, and the necessity stressed for giving the patient quiet and rest. The new edition is, in fact, a model work, and has our highest recommendation.

---

(a) "On Syphonage and Hydraulic Pressure in the Large Intestine, with their bearing upon the Treatment of Constipation and Constipation, &c." By Ralph Winnington Leftwich, M.D., Late Assistant to the East London Children's Hospital, London: J. and A. Churchill. Price 2s. net.

---

(a) "The Diseases of the Mouth and Teeth." By Lloyd T. Lavan, L.D.S., F.R.C.S., late Assistant House Surgeon, National Dental Hospital, Member of the Anerican Society, etc. Part 1.; The Diseases of the Antrum (Maxillary Sinus). London: Adams Brothers, 1914.
wringing the sanitary towel out in antiseptic lotion before applying it, in order to prevent vaginal sepsis from decomposing lochial discharges. Ergot only be given to women—completely emptied, and shall then be administered at least drachm doses, smaller quantities being quite inert. In speaking of eclampsia, the author favourably regards Frommer's modification of Boari's doctrine as a means to facilitate delivery. Taken as a whole this volume gives a very clear and concise account of present day midwifery practice. It contains much that will, doubtless, be new teaching to some, while other things will find it a confirmation of their own routine methods. An appendix containing the statistics at the Rotunda Hospital for the last thirteen years has been added to this edition. The author is certainly to be congratulated on the splendid results obtained, as shown by these carefully compiled statistics. As a text-book for students we know of no other that is at once so thoroughly practical and at the same time concise. Practitioners will find much help and guidance within its pages for which larger treatises will often be consulted in vain.

Through the courtesy of the Registrar-General of Ireland we received a copy of the thirty-nine detailed Annual Report of marriages, births, and deaths registered in Ireland during the year 1902. The reproduction of a compilation of statistics, and much more than a compilation of statistics, as such it gives all the statistics that lay bare the social condition of the people, and compares those of 1902 with those of each year of the decade. By an extremely accurate system of tables and connected diagrams, and black and white charts, the matter is so arranged that the reader has no difficulty in obtaining the desired information. Taking up the statistics of deaths we learn that the number and proportion to the population the death-rate in the provinces and certain counties. The classification of the causes adopted is that of the new official nomenclature of diseases and so presents certain changes. Taking the highest and lowest mortality from disease from twenty-two of the principal causes of death in Ireland, we find the numbers to range from 334 deaths from epilepsy to 11,857 from tuberculosis. It is interesting to note that malignant diseases, including cancer, sarcoma, and cancer, caused 2,861 deaths in 1902, being 32 under the number for 1901, but 344 over the average for the ten years 1892-1901. Before any idea of the wealth of information the report contains, and can be and in his memory of his son. Mr. Carr Wigg of Hove, has left 230 each to King's College, London, the Sussex County Hospital at Brighton, and the Royal Alexandra Hospital at Brighton.

Dr. Steevens' Hospital, Dublin.

At a meeting of the Governors of Dr. Steevens' Hospital held on November 10th, a letter was read from Dr. Henry Tweedy resigning his post of visiting physician to the hospital. Dr. Tweedy's resignation was received with regret, and it was unanimously resolved to appoint him consulting physician to the hospital. A letter was also read from Dr. Hastings Tweedy resigning his post as gynaecologist on account of his recent appointment as Master of the Rotunda Hospital—an event to which we have already alluded in these columns. We learn that it has been decided to fill both vacancies. The Board of the hospital to be held on December 22nd, and as there are some other vacancies to be filled at the same time, notably the vacant post of house surgeon, a considerable amount of interest is taken in the proceedings. We learn that for the senior posts many candidates are in the field. Dr. T. F. C. Kirkpatrick, assistant physician to the hospital, is a candidate for the post of visiting physician, and as he has acted as such in place of Dr. Henry Tweedy for a considerable time past we are convinced that he will be able to present very strong claims in support of his application.

Bakehouse Sanitation.

The important question of bakehouse sanitation has been recently advanced by certain fresh official regulations, as shown by the following letter from the Home Secretary:

Whitehall, November, 1903. Sir,—With reference to previous correspondence on the subject of the proposed of the Incorporated Society of Medical Officers of Health that the standard of air space in bakehouses for each person employed should be raised to 500 cubic feet, I am directed by the Secretary of State to say for the information of your association, that after careful consideration he has come to the conclusion that a case is made out for an Order modifying the present standard so far as regards underground bakehouses and bakehouses in which work is carried on at night by artificial light other than electric light. The Order is required to be published in draft before it is finally

Medical News.

Requests to Hospitals.

Under the will of the late Mr. Richard Thomas, of Ealing, and formerly of Macclesfield and Burnley, the following bequests have been made, subject to a life interest of £1,000 each to the Victoria Hospital for Burnley and District, and the Macclesfield Infirmary, to endow beds in perpetuity bearing the name of the testator's son, William Brindley Thomas; also £1,000 to the Hয়ing Cottage Hospital Endowment Fund, also in memory of his son. Mr. Carr Wigg of Hove, has left 230 each to King's College, London, the Sussex County Hospital at Brighton, and the Royal Alexandra Hospital at Brighton.

Dr. Steevens' Hospital, Dublin.

A LARGEST bazaar will be held on Tuesday next, December 1st, and the three following days, in aid of the furnishing fund for the new buildings of the hospital. The bazaar presents a special feature of interest in that it will be held in the hospital itself, which has not been yet opened for the reception of patients. As is well known, the new hospital represents the junction of the two former hospitals—St. Mark's and Molesworth Street. These hospitals discharged their duties well for many years, but they have become too small for the increased numbers of patients who come for treatment, besides being required to offer more facilities for surgical operations. It is also hoped to effect a considerable saving in expenses by the substitution of a single establishment for the two at present in existence. The new hospital is being built under the direction of a most energetic committee, and is certain to be most successful.

Presentation to Sir Anderson Crichton and Mr. Malcolm Morris.

Sir WILLIAM BROADENT, in the board-room of St. Mary's Hospital, Paddington, last week, made a presentation to Sir Anderson Crichton and Mr. Malcolm Morris, who retire from the work of that institution after a service of twenty years. The gift to Sir Anderson Crichton was a pair of silver candleabra and an album, while that to Mr. Morris took the form, by his own choice, of the Annual Register, in 145 volumes, with a diamond ring for Mrs. Morris and a ring to the horse for his daughter. Sir William Broadent made a graceful speech to his two colleagues, and mentioned that Sir Anderson Crichton had held every distinction in the profession. The gift to Sir Anderson Crichton was his enthusiasm and his energy, and he was the first to establish the Finsen light treatment in this country. One of the greatest distinctions possible for an Englishman had been conferred upon him when he was asked to go to America to deliver the Lane lectures, in which such distinguished men as Sir Michael Foster and Professor Allbutt had preceded him. In reply, both the retiring surgeons spoke of the respect with which they regarded their connection with the hospital, and Mr. Morris observed that in working for the poor he had reaped a rich reward in their gratitude and heartfelt thanks.

Hospitals as Professor.

The Medical News having appointed a well-known Zürich homoeopath to the Chair of Pharmacognosy and Pharmacodynamics in the University of Leyden, I hasten to give the wishes of the medical faculty, a considerable amount of interest has been excited in Dutch scientific circles as to the results of the quarrel. The issue of this action will be awaited with considerable interest.

The Royal Free Hospital for Children and Women, Waterloo Bridge Road, London, S.E.

The annual Court of Governors of this hospital will take place at the Mansion House, at 3 p.m. on Monday, January 18th, 1904. The President, the Right Hon. the Lord Mayor will occupy the Chair. The Lady Mayoress Miss Ritchie, also is a member of the Court of Governors of this hospital, of which H.R.H. the Duchess of Albany is Chairman. The Board wish to thank Mrs. Charles Churchill, of Weybridge Park, for the sum of £104 18s. od. handed in as the proceeds of the drawing-room meeting held at her house last week.

Sanitary Institute.

A provincial sessional meeting of the Sanitary Institute will be held at the Town Hall, Leicester, on Saturday, December 5th, at 11 a.m. A discussion will take place on the Collection, Disposal, and Utilisation of Town Refuse in Leicester, to be opened by Mr. Frank W. Allen. On December 6th, at 8 p.m., a discussion will take place at the Parkes Museum, St. John's Lane, London, W., on the flooding of basements in London by sewage, which will be opened by Mr. Maurice Fitzmaurice, C.M.G., and Dr. H. R. Kenwood, the Chair will be taken by Sir Benjamin Baker, F.R.G.S. Tickets for visitors may be obtained on application to the secretary, Mr. E. White Wallis, at the Parkes Museum.

The Liberal in the Baylis's Colridge Case.

The cause of the action lay in the reading of a written statement at a meeting of the Anti-Vivisection Society at Dr. Baylis's Colridge Colledge on May 1st, 1903, and also by causing it to be published in the Daily News of the following day. The statement declared by the defendant to be that of an eye-witness, was as follows:

"I have attended many lectures at the Physiological Laboratory of University College. I have constantly heard there the long-drawn howling and whining like that of dogs in terror and agony. When the door of the lecture-room was opened the sound of this grew louder; when the door was again shut the cries ceased for a short time. On February and this year I saw an experiment by Dr. W. M. Baylis on a dog at this laboratory. A big brown dog of the terrier type was brought into the lecture-room, and stretched on the table. Its legs were fixed. It was tied to the board, head held firmly in a head holder, and it was muzzled so tightly that it was now deprived of every power to give audible expression to pain. In the skin of the women there were several scarcely healed scars and wounds; on one of them that seemed rather fresh there were left a pair of clamping forces. It was evidently not the first time that the dog had been used to serve science. The internal organs of the abdomen had surely had their turns of operations in previous experiments. The experiment was opened widely for the stimulation by electricity of a certain gland. The dog struggled forcibly during the whole experiment, and seemed to suffer extremely during the stimulation. No anaesthetic had been administered in my presence and the lecturer said that about another anaesthetise the animal having previously been made. When an anaesthetic has been given good care is generally taken to tell the audience about it, and, as a rule, the anaesthesia must be kept up. Professor Cunningham stated of the anaesthetic used. Nothing of the kind was done here, and the violent and purposeful struggles of the animal indicated complete consciousness. The dog was carried out still fixed to the board after half an hour." "Is this not," defendant asked, when he had heard the above statement, "enough to make the blood run cold? If this is not torture, let Mr. Bayliss and his friends—Lord Lister and Sir Victor Horsley—tell us in Heaven's name what torture is."

Hospital Shopping Day.

It is officially announced that the Hospital Shopping Day movement has resulted in an addition to the King's Hospital fund of a sum of £350. It is not the total outcome of the movement, but only the total of the contributions received from a number of the firms which joined, and that in some cases the payments actually made are only on account.

Presentation and Dinner to Professor Cunningham.

On Saturday night the past and present pupils of the Medical School of Trinity College gave a dinner at the Shelbourne Hotel to Professor Cunningham, who for a number of years filled the Chair of Anatomy in the Medical School of the University, and presented him with a massive silver loving cup of Celtic design, manufactured by Messrs. West and Son, of Dame Street. The presentation was made at premises of Trinity College. The King's health was proposed and before he replied. When Professor Cunningham had helped himself from it it was carried by Dr. Halahan and Mr. Mc'Knight round each of the tables; all present followed the example of the guest of the evening, after which it was replaced on its plinth opposite where Professor Cuningham sat. Professor A. F. Dixon presided, and the dinner was largely attended by many of Professor Cuningham's past pupils; only a few of the guests were representatives of Dublin University, the Royal Veterinary College, the Royal Dublin Society and the Royal Zoological Society of Ireland. The toasts proposed were those of the King, "Professor Cunningham," and "Dublin and Edinburgh Universities. Professor Cunningham, in replying to the toasts of his health said that the twenty years which he had spent in Trinity College were, without doubt, the happiest and most profitable years of his life, and it would ever be to him a memory filled with pride that he had had the privilege of associating during that time with the great and distinguished men of the College, and that he had been permitted to take a small share in the development of the Medical School during what had been a really progressive stage in his career. He congratulated the College on having secured the services of Professor Cuningham as an alumnus. The proceedings of that evening throughout the whole of his life would be one of the brightest spots in his memory, and he again thanked them from the bottom of his heart for the honour they had done him, and for their magnificent presentation.

The dinner lasted to a late hour, and was most successful in every way.

On Saturday, the 21st instant, the united employees of Messrs. O'Donnell Limited, and Southwood, Smith and Co., Ltd., held their annual dinner at the King's Hall, Holborn Restaurant, which proved a great success from every point of view. The front page of the menu card was filled with the title-pieces of the many important journals among which that of The Medical Press and Circular figured prominently. The dinner was wound up by some excellent speeches and a variety of first-rate musical and vocal entertainment.
NOTICES TO CORRESPONDENTS.

APOINMENTS.

BLACKBURN, ROBERT J., L.R.C.P.Edin., Royal Army Medical Corps, Clinical Assistant in the London School of Gynaecology (the Hospital for Women), Soho Square, W.2.

COTTRELL, F. A., L.R.C.P.Edin., L.R.C.P., Glasc., Assis-

Appointments.

Notice to Correspondents, Short Letters, 

FRANCES TROTTER, THOMAS E., F.R.C.S.Edin., Resident Medical Officer to the St. Mary's Hospital for Sick Children, Paddington W.,

LAWRENCE, DAVID, M.D.Edin., Resident Medical Officer to the University College, Cardiff.

LEWIS, E. R., M.B., M.S.Edin., Physician to the Royal Hospital for Diseases of the Chest, City Road, K.C.

McDAVID, Dr., Medical Officer of Health for the City of Limerick. By his Excellency the Lord Lieutenant of the County of Limerick District Male Prison, in room of Dr. T. Geoghegan, who resigned after more than thirty years' service, constitutes one of the greatest sanitary advances of the generation.

SECOND PUBL. — There is no rule to compel a medical man to notify a case as small-pox, so long as he entertains any doubt in his own mind as to the possibility of the disease being chicken-pox. When the diagnosis is clearly that of the more serious malady, not a moment should be lost in notifying. It is always well to regard a diagnosis of chicken-pox with the greatest circumspception and suspicion.

F. J. JONES (Cardiff).—The advertisement you send us is much what no respectable newspaper would disgrace its columns by insertion. Unfortunately, the only law against advertisements of that class is a moral one. The only remedy we can suggest is not to buy the newspaper.

BELFAST.—We regret to say that in our last week's issue the para- graphic of the latter part of page 12 was given by Thomas Hon- ton's name as "Hastock." There is no need to point out the error to Belfast; but as teenagers in the work bearing the name on the Pathological Laboratory, Queen's College, is well known and appreciated.

VALUE OF SAMPLES.

To the Editor of "The Medical Press and Circular."

Sir,—We were greatly amused by the pleasantry which appeared in your columns last week under the above heading, but are still in doubt as to what became of the pop. Did he exercise the wisdom of his kind and call it "Black Betsy" and thus hasten the sharp-witted, courteous, and strong of bone and muscle as a well-dressed doggie should be? Did he fill his pockets with impoverished white flour for dowsing out with the agencis of a disregardful disorder lay his head on the "little pillows of wheat" and so pine away? We guess that there is more of the common-sense and discretion of the dog that we are, Sir, yours truly.

THE SHEDDEN WHEAT Co.

We feel that in fairness the above should be remarked. The short history in question, unfortunately did not say what was the ultimate fate of the wheat. —Ed.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 27th.

HOSPITAL SOCIETY OF LONDON—Lecture.—Address of the President on "The Address of the Medical Act on Irish Training Institutions and Nurses."—Sir J. Denny.—An extract from the "Socinian," with notes on a case. Exhibits by card.—Dr. T. Bown.—(1) Pustules complicating paroxysmal asthma; (2) An interesting case of hepatic hernia.—(3) Cancer of the cervix removed by abdominal hysterectomy. Dr. G. H. L. Druce.—Two cases of hysterectomy for morbid myoma.—(4) Myomectomy. Specimen.—Dr. Smyly.—(1) Fibrocytoma. (2) Giant pelvic tumour. Dr. A. Martin.—(1) A tuberculous case of tabic tuba—stagnante by torsion of the pedicle. An interesting tubo-ovarian abscess sac. Dr. Grieve.—Ruptured tubal pregnancy with inflammation of the Fallopian tubes and adnexa.

ROYAL ACADEMY OF MEDICINE (Dublin).—Section of Obstetrics President.—Address of the Department.—The Address of the Medical Act on Irish Training Institutions and Nurses. Paper—Sir J. Denny.—An extract from the "Socinian," with notes on a case. Exhibits by card.—Dr. T. Original Communications.

THE CLINICAL AND SURGICAL ASPECTS OF CANCER WITH A VIEW TO EARLY OPERATION. (a)

By Sir LAMBERT H. ORMSBY, M.D.,
President of the Royal College of Surgeons in Ireland, and President of the Surgical Section of the Royal Academy of Medicine, Ireland.

At no time in the progress of surgery has the question of malignant disease been so fully and widely studied as now, as regards its causation, progress and cure. Being a member of the Committee of the Cancer Research Fund, whose headquarters and central laboratory at present are at Examination Hall, Victoria Embankment, London, I have had exceptional opportunities of learning what has been done, and what is proposed to be done in the near future, by the Committee, from the General Superintendent, Dr. E. F. Bashford, and his able assistant, Dr. J. A. Murray, the active experts who have been appointed to grapple with the important problem of the causation of cancer. And when I say cancer, I mean all forms of malignant disease.

Of recent years, owing to the great advance made in our knowledge relating to pathology, histology and bacteriology, a clinical worker is rather prone to depend too much on the microscope and other means of scientific precision rather than on the knowledge conveyed by the hand and the naked eye of the local appearance of the diseased area alleged to be affected. The pioneers of our profession in days gone by, in the absence of all the present scientific instruments of research, so useful and yet at times so misleading in the diagnosis of the various growths and enlargements in different parts of the body, believed themselves able, by constant observation and long experience, to accurately distinguish at a glance between malignant and benign growths by such means and conditions as:

1. The physical inspection and palpation of the part.
2. The rapidity of growth, or the reverse.
3. The amount of pain present.
4. The mobility or adherent nature of growth.
5. The implication of glands in the immediate neighbourhood of the growth.
6. The appearance of the patient, whether gaining or losing weight, and whether suffering from that particular form of cachexia so common when malignant disease has been present in the system for any length of time.

I fear nowadays we train our students to rely too much on the scientific assistance they receive in the histological laboratory, and to neglect the long and close observation in wards and out-patient depart-

ments of hospitals so necessary in clinical investigation, in fact, throwing away the substance for the shadow. I wish to say, however, that it must be clearly understood that I do not decay in any way the close study of pathology, histology, or bacteriology. But what I consider to be the proper sequence of study is first to inquire into all the clinical and naked-eye appearances of a growth as regards its progress, history, supposed causation and environment, and when these facts have been accumulated, crude though they may be, then to seek the further assistance of the microscope and other means of scientific investigation. Over and over again I have found distinguished microscopists differ as regards the nature and structure of a growth submitted to them for examination. Again, I have at times found that growths have been declared malignant or benign as the case may be, and the subsequent history and clinical progress proved beyond all manner of doubt that the opinion given was erroneous.

A great effort is now being made to penetrate the darkness in which cancer has hitherto shrouded itself. The different research committees in Europe and America are bravely endeavouring to arrive at the true solution of its causation, and if their crusade against the dread enemy prove successful, what benefit must accrue to mankind! There is scarcely a home, rich or poor, that has not directly or indirectly suffered from its ravages, but if the great problem of its causation were solved I feel certain cancer could be prevented, “if preventible, why not prevented?” in the words of His Majesty the King.

The consideration of the question as to how these new growths arise has exercised the minds of the most distinguished experts the world over, and theory after theory has been built up in the vain hope of solving the problem, and cause after cause has been assigned as the true instigator of the disease in this exhaustive study.

We must first consider that in ideal life the cells comprising the essential and living elements in each organ of the body form an harmonious ever busy community, active for the welfare of the body as a whole. In accordance with the dictates of biological laws assigning to each and every member a special field of usefulness, there exists a mutual understanding of give and take among the members of the cellular commonwealth. Cell is independent on cell, organ on cell and cell on organ, in one way or another. In their several spheres some cells are more active, others more passive, but the difference in activity involves no subjugation of the passive members to the assertiveness of the more active.

Various agencies may upset the states of equilibrium described, and the result is disease. The agencies causing disease may come from without or arise within the organism itself. In regard to most diseases we have no difficulty in ascertaining whether the agency responsible has entered from without or has arisen within. There is, however, one exception, for the nature of cancer still remains a great enigma. In cancer the harmonious equilibrium of cell life is sadly upset, and there are no certain indications whether the
new growth is situated takes place by infiltration of cancer cells between the healthy surrounding cells; it must be distinctly understood that the latter do not become cancerous—they are merely passive sufferers under the cancerous activity of other cells, and may be removed from the body by surgical or other means. The blood, and therefore food, supply; it has even been stated that the cancerous cells attack the surrounding cells directly, and, cannibal-like, devour them, or by excretion of noxious influences cause the surrounding cells to rot, or disappear before their advance.

It is obvious that the invasion of surrounding tissues by infiltration will have serious consequences whenever a vital organ, an important nerve or vein is involved. The malignant new growths which first develops is said to be the primary cancer, and the site at which it arises is called the primary site. The primary growth may enlarge locally in the way described, or by continuous extension of the process of infiltration come to involve tissues at some distance from the point of origin, especially when the extension proceeds along the lymph channels. Thus transported daughter colonies of cancerous cells may develop as secondary new growths in sites some distance from the primary site. Extension or, more correctly, dissemination of a malignant new growth may also occur in a somewhat different way, and at any stage in the development of the primary growth. Malignant new growths may spread like any other tissue, and are, as a rule, plentifully supplied with blood-vessels, some of which have developed along with the cancer. If a few of the cancerous cells of the primary growth find their way into one of these blood-vessels, the cells are carried by the blood stream, or if they have found their way into lymph spaces by the lymph stream to a distance, they find a resting place in new sites and in remote centers. The cancerous cells which have thus been transported also develop into daughter colonies, as secondary malignant new growths in secondary sites, and without any direct connection with the primary growth.

Much attention has been devoted to the question of the manner in which cancer extends in order that the distinction between this process and what is known as infection in other diseases may be readily comprehended. In the infection of living cells by a parasitic virus of any kind known to us, the infection begins by transference from cell to cell of the infective agent.

Cells transported or transplanted from the primary site of the disease can only be responsible for further infections if they at the time are also vehicles containing the virus in a form which will permit the virus to pass into the normal tissue and find exit from its vehicle and primary host into a new cell.

Thus, in all the infections and parasitic diseases known to us the process of extension is something very different from what occurs in the case of cancer, where the cells involved are all the direct genealogical descendants of those first afflicted. If a primary cancer of the liver give rise to secondary cancer in the lung, in the bones, in the kidney, to put it grossly, they are simply bits of atypical and not a typical liver growing in the liver itself, and lineal descendants in the lungs, bones and kidneys, with dire consequences alike to them all. We do not know whether the process originated in normal liver cells becoming abnormal, or in the presence at the outset of cells which had always been abnormal, and never really a part of the liver itself.

Cancer may have its primary site in any tissue or organ. The primary site is of importance in determining the form which the cancer will assume, for a cancer is always a more or less perfect imitation of the tissues in which it first finds its starting-ground. Indeed, cancers are classified according to the tissues which they most nearly imitate. For us it is sufficient to state that the two great groups of cancer are those in which the higher epithelial forms of cell development are present, and even fresh new growths in organs remote from the original seat of the disease.

The invasion of the tissues among which a malignant
The former are known as carcinomas, and the latter as sarcomas.

What has been said, it is clearly the bounden duty of the surgeon, the moment a suspicious growth or tumour is discovered, to advise its immediate removal. There is no use in waiting for further evidence of malignancy. The sooner the tumour is extirpated the sooner the danger is removed from the patient. Clinically, one finds slow-growing and quick-growing cancers. No two malignant growths run exactly the same course. But we know that slow-growing gives the best chance of non-recurrence after removal than rapid-growing cancers. There is no doubt that a large part of the success of operative surgery in malignant disease depends on early diagnosis and early extensive removal.

On this subject Mr. Butlin says:—

"Hence the supreme necessity for a continued and active study of the diagnosis of malignant disease in every part of the body, and not only of actually existing malignant disease, but of the conditions which precede the occurrence of malignant disease, predisposing conditions and pre-cancerous stages."

Early diagnosis is not always followed by early operation, for sometimes it is almost impossible to persuade the patients or their friends to allow an immediate operation to be performed because they feel no pain or inconvenience in the part, and have no idea of the danger of postponed operation as being the means of destroying the very best chances they have for its removal and non-recurrence when removed. In other cases a tumour may be overlooked for a considerable time and is only discovered by accident when it has assumed considerable dimensions and attended with secondary growths and glandular contamination.

In the report of the Cancer Research Fund the figures for some 3,000 cases of malignant new growths are given, and are tabulated in such a way as to compare the clinical diagnosis with the result of the pathological examination made after operation or post-mortem. These figures, while on the one hand they bring into prominence the difficulty and in many cases the impossibility of diagnosing the presence of cancer, also show that surgeons recognise the importance of early diagnosis. In this report the cases of malignant disease are divided into two groups, accessible and inaccessible, and attention is drawn to the large number of "accessible" cases which the surgeon in the absence of the patient has diagnosed as malignant new growth, which subsequent pathological examination has not confirmed. There can be no doubt that the surgeon has been justified, however, in operating in these cases, not only because he was unable to say that the condition was non-malignant, but also because by treating them as if they had been malignant, he was acting in the best interests of his patient. In view of the impossibility of being sure of the true nature of the tumour-like formations, it is probable that as time goes on the number of cases in which an operation is performed as if for malignant new growth will increase rather than diminish. This sounds very much as if we were recommending a needless use of the knife, but where the only hope lies in a timely operation it is surely better to be too early than too late, especially as when the tissues of those doubtful cases are submitted to the skilled histologist he also is not prepared to express a definite opinion, either for or against the tissue being that of malignant new growth.

It is the surgeon's duty to operate at the earliest moment, and, therefore, he need not regret having operated pre-maturely, not to have operated too late, or a malignant growth. The surgeon's duty to his patient requires him to take this risk, and it is the duty of those who have the opportunity to educate the public and the profession to recognise the advantages of early operation, even if the result prove that such operation was at the time somewhat premature. In the later stages of malignant disease, when it is so far advanced that its complete removal is quite out of the question, I consider the surgeon is not justified in recommending removal in notoriously hopeles cases by operation, though I regret to say they are frequently performed for reasons not different from those underlying the conduct of young and enterprising surgeons, who allow their operative zeal to outstrip the surgical needs of the case. I have seen patients subsequently who have submitted to incomplete operations of this kind far and away worse after the attempt than before. It was a question to me whether I was more surprised at the fortitude of the patient or the courage of the surgeon who undertook the responsibility of carrying out an operation which not only risked a valuable life, but gave the patient the false hope of recovery which he quickly perceived was only a delusion.

Again, the performing of such hopeless operations on the off-chance of giving temporary relief might be its failure be the means of preventing other early operations being performed in favourable cases, where there is a good and reasonable chance of being of service to the patient, instead of abandoning him to a painful and lingering death, the sad termination of many inoperable cases of cancer.

SOME QUESTIONS
IN
SEASIDE CLIMATOLOGY. (a)

By ALFRED F. STREET, M.A., M.D., D.P.H.,
Wengtie-on-Sea.

PART II.

(Concluded from page 581.)

PROFESSOR BUCHAN tells us that the fundamental element is of climatology, the temperature of the air. Only 50 per cent. of the total solar radiation due, so to speak, on a given area at the sea level ever reaches that area. Even when the sun is at the zenith the amount which arrives is very much less than 100 per cent., and by no means all of this is heat, especially as our atmospheric envelope is more transparent to the rays of shorter than to those of longer wave length. Now the temperature of this air is one of the few things we need not argue about, for it has been observed daily steadily and systematically for some three and twenty years by the indefatigable observers of the Royal Meteorological Society. The maxima, the minima, the average, and many other data are on record. Without quoting rows of figures, the facts are that the average daily range is moderate (namely, 11°), as that of every seaside place must be, owing to the moderating influence of the sea, and that the average temperature is that of London, partly, no doubt, owing to the fact that the sunshine average is more than 20 per cent. more at the former than at the latter.

Owing to the influence of the Gulf Stream, aided by the preponderating prevalence of south-west wind, the winter isothermals lines of Great Britain lie nearly north and south, instead of east and west. The isothermic line of January slants across England from Dover to North Wales and passes thence along the Wlsh coast of Scotland. The frequency of barometric variations near the sea may tend towards the attainment of that perfection of organic life which is said to depend on the alternations of excitement and repose.

There remains to be mentioned hydrogen, which is undoubtedly present in our atmosphere; but for every gas there is an altitude at which it is as the many molecules diffuse from as inward in unit time, and recent physical deductions lead to the conclusion that such hydrogen as the

(a) Presidential Address delivered before the British Palaeontological and Climatological Society, on Friday, October 25th, 1909.
earth exhales, so to speak, into its atmosphere from the pores of certain minerals leaves the extreme corners of our atmosphere on its way through interplanetary space to join the atmosphere of the sun, the gravitational attraction of the earth's mass being overcome by that of the sun, but even if it stayed with us it is not clear what physiological effect it would have except as a diluent of oxygen.

Is there a greater percentage of oxygen in sea air and land air? I know of no evidence that there is, though Dr. Angus Smith found 92 per cent. more than the average in the air of the Western Highlands, and although volume for volume there is, of course, more oxygen in sea air than in mountain air, but if there be any such preponderance, however small, it has been completely overshadowed by the effect of the less oxygen in sea air during summer and winter than in spring and autumn.

Just as it is not possible to predicate the therapeutic effects of a given water from a consideration of a laboratory analysis of it, so it is not at present possible to explain the difference in physiological effect between the apparently similar air of different places.

At one of the earliest meetings of this Society Dr. Snow very rightly told us that it was not so much to the composition of a water that we must look as to the results upon the patient that experience had shown could be obtained. We must not neglect the teachings of experience only because we cannot explain them, and this applies to air quite as much as to water, and we have in remembering that the best chemical analysis would be clouded by an unrecognised element, and it is only recently that the very existence of several normal constituents of the atmosphere has been established. Helium is an apparently inert element, but is it certain that its presence and that of argon in the air and of one of the other rare gases has no influence on the therapeutic effects of that water? Can it be certain that it is there merely in solution? If not, it may in combination be capable of results as astonishing as those of some compounds of the typically inert nitrogen.

Is it lawful to surmise that some as yet unknown element gives its peculiar effect to the air of some localities, or shall we find our explanation in the new and mysterious property introduced to us by Becquerel as radio-activity?

It is true that hitherto the chief sources of radium and polonium, the best known of the radio-active bodies, are minerals such as pitchblende and chalcolite, and not the ocean, but Whewell compared one of our atmosphere's gases by its way of passing through a vessel filled with filtered rain-water and in snow and hail, especially during a thunderstorm, and it is not destroyed by heating the containing vessel to dull redness. Professor J. J. Thomson has extracted at least two radio-active gases of great density from many different deep well waters, and announced that their intense rays are emitted in kind from that of radium in that they render radio-activity a negatively electrified surface, and not an unelectrified one. Strutt finds radio-activity to be widely diffused, and that there is some in most metals. Sir Oliver Lodge surmises that radio-active emanations (the so-called X-rays), which are believed to consist of actual atoms of matter, may proceed from many substances, without our being as yet aware of their existence. Messrs. Rutherford and Allen have found that a negatively charged body exposed in the air becomes radio-active, and they conclude that, therefore, there is some radio-active substance in the atmosphere.

Sea water has not, it seems, hitherto been studied to examine its properties, but it is reasonable to suppose that in this respect it is more like to resemble well water than surface water. Before the discovery of radio-activity Dr. Julius Hesse wrote thus:—

"There can hardly be any doubt that there are still other modifications in the composition of the atmosphere which have some influence on the human organism, but which have not yet received any attention."

May we expect any help from a consideration of variations in the electrical or magnetic conditions of different localities which Dr. Solly considers to be important? The mysterious power of magnetism tempts us to ascribe to them any characteristics which are apparently not otherwise explicable, just as the ancients invoked the aid of magic, and it may be that we shall find in them the answer to this problem, for undoubtedly some people are especially sensitive to abnormal atmospheric electrical conditions, and it has been experimentally shown that strawberries ripen sooner and in greater numbers when grown under the influence of an electrical field.

A beneficial effect has been observed in the case of plants grown under one of the poles of a Wimshurst machine, and this cannot be ascribed to ozone, which is formed chiefly at the positive pole, whereas the plants in question did best near the negative pole. Messrs. Elster and Geitel have arrived at the conclusion that free ions exist in the atmosphere, and if so they may well be of physiological importance. Now we are told that the average amount of electrical force is least when the wind comes from a point midway between N. and N.W.—from between the true and the magnetic N. poles—and yet this is the wind which seems to me to deserve more than any other the epithets brisk, bracing, stimulating. But Professor Tait writes that "our ignorance of the source of atmospheric electricity is singularly complete."

Let it be granted, then, and granted I think it must be, that the atmosphere of some localities has special properties, and let it be admitted that we cannot at present express these properties in terms of any known element or force; then there arise two questions:—First, under what circumstances are these properties therapeutically valuable? Secondly, can we in any way preserve, intensify, or diffuse some of a radium-like property?

In attempting to answer the first of these questions a sentence of de Chaumont seems apposite, namely, that "to the healthy meteorological conditions are of little moment apart from personal comfort." On the other hand, what patients would derive benefit from such a climate, and for what particular activity is different? When we try to work out the answer to these questions we find ourselves in the position of the medical man who is called upon to prescribe a diet, not for a disease, but for a patient.
It is comparatively easy to prescribe for an abstract disease—that is what the text-books do—but how difficult for a concrete patient, and one, too, who probably has strong and inconvenient leanings and antipathies, or idiosyncrasies, such, for example, as an unusual sensibility to diminished atmospheric pressure similar to the case of cats, who, according to Dr. Burney Yeo, can be kept in certain localities of high elevation. The determination of principles for the selection of climates is one of the most vitally important services which this Society can render to our profession, for it is impossible to trust most of the hard and fast rules which are offered for our guidance.

Dr. Leonard Williams has, recently said, in the case of some diseases certain climatic combinations are to be avoided. There are constitutions in which a stimulating atmosphere produces a feeling of general discomfort, and people who have idiosyncrasies with respect to climate just as others have with respect to drugs.

Now, just as those who make the fewest mistakes in the prescribing of diet are those who consider the likes and dislikes, and who know the ordinary mode of life, of a patient, so shall we most successfully give advice in respect of climates if we carefully consider not only the name of the patient's disease, but his climatological likes and dislikes. The man of open windows is likely to thrive best in stimulating air, and the man who is sensitive to draughts may be better suited by a more sedative climate, for in some persons the automatic control of the vaso-motor system is clearly either undeveloped or too slow. Nor can we afford to lose sight of the great importance of aspect. How often it happens, especially in the spring, that the climate of one's own a room or garden, takes the form of a climate on the north side of a wall, and another on the south side.

There is no need to insist on the need of avoiding dry, cold winds in cases where damaged kidneys are able to do only part of their duty, or for pulmonary cases enfeebled by prolonged suppuration, nor does anyone in England need to be reminded that the journey from London on the South Coast in summer weather, or indeed upon winter weather in winter time. Most children are the better for a stimulating climate, and of the people best suited by a sedative climate a large proportion are aged.

My second question is soon answered: Man, it has been truly said, "cannot change the weather by any device yet suggested," not even by American methods of rain production, yet does he affect climate by removing trees (for vegetation increases the humidity of the air, though not the actual rainfall) and by drying the soil by works of drainage, or by supplying it with water as by means of the Assouan dam, and by the careful selection of previously barren spots.

We can preserve the life-giving properties of our air by cultivating the highest ideals in sanitary matters. It is of little use to live at the seaside with shut windows and in air used up by overcrowding and fouled by dust and by pestilential sewers and filthy dust-bins, and it is universally agreed that should be done, that dry sun-salve and a clean underground air are essential to high sanitary excellence. Parasitic microbes grow most readily in warm, moist places, and it has been calculated that in the course of a single day a man inhales 10,000 litres of air, so that determinations of the number of living microorganisms present in the atmosphere at the ground level at once assume great importance. Now it has been shown on the one hand that an adult in Manchester inhales in the course of ten hours 37 millions of microbes, and that in London there are present from 80,000 to 210,000 solid particles in each cubic centimetre of air, and on the other hand that in the air of the Western Highlands the corresponding number is only sixteen.

In these respects a great responsibility rests upon our profession, the responsibility of helping to educate and influence not only our patients as such, but all who hold office in the public bodies by which we are more or less misgoverned.

Finally, I would ask you to assent to this proposition. The places in our islands where we enjoy most often a pure and stimulating atmosphere are those the air of which comes most often from over the sea. The more directly it comes from the sea and the longer it has been away from land the more pure it is. Its stimulating properties depend partly upon its relative humidity, partly upon its temperature, and partly upon factors not yet thoroughly understood.

"I speak as unto wise men, judge ye what I say."

CASE OF

TYPHOID PERFORATION: LAPAROTOMY—RECOVERY

By M. C. STAUNTON, M.D., B.S., &c., Surgeon to the Children's Hospital, Temple Street, Dublin.

Or the many complications liable to arise in the course of an attack of enteric fever none is more dreaded than that of perforation, so that no surprise need be expressed at the keen interest taken by the profession in the attempts which have been made within the last few years to deal surgically with such a catastrophe. So far, in this country at all events, success has not attended on these efforts as often as one would hope for.

But when we remember the condition of the patient at the time when perforation most often occurs we cannot expect such a large measure of success as when a similar emergency arises acutely in a previously healthy subject—e.g., from bullet wounds, stabs, &c. I know we may look forward to greater success when physicians come to realise the very important fact that typhoid perforations are not "necessarily" fatal. I remember the time, not so very many years ago, when surgical intereference in such a complication was not even discussed. That time, I trust, is happily past.

The following notes of a case of perforation may now be of interest.

On September 28th, 1903, I saw a little girl, aged 6, whose clinical history was to the effect that for some months she had been in indifferent health, attributed by the parents to a severe attack of whooping-cough in the previous spring. However, she had been going to school up to September 24th, on which date she complained of headache, had no appetite, vomited, and was generally sick. She continued in this condition up to the 28th, when I first saw her. She looked worn and pallid, with furred tongue, constipation, temperature 103°, pulse 120. I ordered her to bed and to be kept on whey and chicken-tea and three grains of calomel in three doses. Next day I examined her in bed, found the temperature 104°2, pulse 120, abdomen dis-
tended, but not enough to prevent palpation of the spleen, which was distinctly enlarged. There were two or three spots on the abdomen. I diagnosed typhoid fever. Next day I was told she had had a very restless night, with some abdominal pain and vomiting, temperature 103°5, pulse 130. I saw her in the forenoon of October 1st, when I found her with great abdominal pain, distension and tenderness, vomiting, thighs drawn up and looking very haggard. I could only see peritonitis in the picture, and recommended her removal to hospital so as to be ready for operation in case I might so decide. In the absence of the father, the mother would not consent to anything, even to a consultation. I saw no objection now to giving 6 minims doses of liq. morphiae every three or four hours, according to the severity of the pain. I also stopped all alimentation by the mouth, except sips of water from time to time. The same evening the patient seemed so much easier that the father decided to wait till the next day. She had no sense of pain during the night, but another dose of the morphine relieved it.

On the morning of October 2nd the narcotic was still acting, much to the parents' delight, but the temperature had fallen to 100°, and the pulse gone up to 140. After many interviews they consented to follow my advice, send the child to hospital, and allow an operation. In hospital that afternoon her temperature was 97°, pulse thready, and general appearance most unwonting. I had 1-30 gr. strychnine injected before operating, and repeated with digitalin afterwards.

On opening the abdomen the intestines were covered with lymph-flakes, abundant and tough, and separable only with difficulty. On discovering the caecum, I worked backwards along the small intestine, and about eighteen to twenty-four inches from the valve I found a small hole in the convex border through which bubbled gas and pale brown intestinal contents. Similar extravasation lay in the vicinity. I did a continuous Lembert suture. Near this perforation was a small yellow patch, like the head of a boil, appearing through the peritoneum and undoubtedly another ulcer on the point of giving way. This was similarly sutured, and between the two a third ulcer looked so dangerous that I doubled it in also. I was obliged to finish up with a hasty examination of the rest of the intestine, flush out with hot saline solution, and leave in a gauze drain. The actual operation occupied less than twenty minutes, thanks, in a large measure, to the very able assistance of our assistant surgeon, Dr. D. Farnan.

One hour after operation the temperature was 99°2, pulse running, and she seemed too weak to complain of anything, but there was no vomiting of consequence.

The after history presented nothing of interest, except that the patient held on to the slender thread with the tenacity of childhood, had a temperature of 101° two days later, about which point it oscillated for a week, and gradually declining, her convalescence was comparatively rapid.

The only point I draw particular attention to is that from the time I diagnosed peritonitis, and that the most likely cause of it was perforation, the child was allowed only sips of water and the few minims doses of morphia.
from any severe illness, and that he had lived a very healthy and active life. The swelling in the neck had been about two months slowly increasing in size. On examination, a tumour was found below the angle of the jaw; it was about the size of a small orange, and it pulsed freely in all directions. The patient complained of pain in the neck and head, but the tumour was not tender. For an old man, his general condition was fairly favourable.

On March 4th, the common carotid artery was ligatured below the omo-hyoid, and all pulsation was at once arrested. Tendon ligature was applied. A few days after the operation he became very talkative and excited, but after two weeks' careful treatment his mental condition steadily improved, and the wound rapidly healed. When he left the hospital on April 4th, the sac was soft and shrunken.

Remarks.—There was no history of syphilis; but his friends stated that in former years he had lived a very intemperate life. The patient was in his seventy-fifth year, and at the time of the operation the vessel was dilated and the external coats felt firm and rigid.

Ligature of the carotid artery is often followed by cerebral disturbance and this occurs with very variable severity. The symptoms may set in at once or many days may elapse before they appear. Early cerebral excitement is probably due to the reduction of the blood supply to the brain; but later on it is the prelude of dangerous structural changes. In pre-aseptic days cerebral softening and septic complications resulted in a very high mortality, but with the aid of modern precautions we can now protect our patients against many dangers.

Royal College of Surgeons in Ireland.

DENTAL EXAMINATION.—The following candidates have passed the final examination for the Licence in Dental Surgery:—Mr. W. Holton, Manchester; Mr. H. J. Anderson, Galway; Mr. H. D. Black, Dublin; Mr. E. C. Pelissier, Clonmel; Mr. W. V. Perchon, Cork; and Mr. J. Smith, Dublin.

SPECIAL ARTICLES.

BRITISH SANATORIA FOR CONSUMPTION.—XXII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE RUDGWICK SANATORIUM.

On the borders of Sussex and Surrey, and easily accessible from London, lies the little village of Rudwick, almost unknown to the ordinary tourist. Here, at a distance of seventeen miles from the sea, and at an altitude of 400 ft., well sheltered from the northern winds by the Surrey range of hills, is situated Dr. Annie McCall's Sanatorium for the Treatment of Consumption. A ten minutes' walk from the station, up a gentle slope, lands one at the sanatorium, the front view of which suggests nothing more than a small, homely country house, with its low porch and creeper-covered walls. This building is used entirely for administrative purposes, and contains rooms for the resident medical officer, the matron, and the various members of the domestic staff.

The patients' block is a large house erected in the sloping grounds behind, and consists of thirty rooms, those on the ground-floor having French windows, while those above have ample window space, which allows of an abundant supply of fresh air to patients who have to be kept in bed. The bedrooms present a very attractive appearance with their simple white furniture and small open fireplaces.

In the grounds, in addition to a number of shelters of various sizes, which mostly face south to catch all available sunshine, are two larger erections: one is a glass-house, well raised above the ground to allow of subventilation, and fitted with sliding windows, which serves as a dining-room for the patients. The other, a wooden building, fulfils the purpose of a recreation-room when required.

The patients, who are under the constant supervision of a resident medical officer and experienced matron and nurses, are treated on strictly hygienic principles. An abundance of nourishing food is given at frequent intervals, and a constant supply of fresh air is insisted upon, and the patients made to live all day in the open; many of these, when the weather is suitable, also sleep outside with the sky as their only roof. Dr. McCall and some of her staff set them an excellent example in this respect, always preferring, in the summer, to have their beds put up in the garden.

Hill-climbing, regulated according to the strength of the individual, and regular walks form part of the daily routine, and the sanatorium being placed on a western, gentle slope is admirably situated for this purpose.

A special point is made of hydrotherapy, and all the patients have a daily cold bath or sponge down.

Dr. McCall visits the sanatorium regularly every week, and often spends the week-end there, so that she can thoroughly investigate every case and personally watch the progress of each patient. On those occasions she gives a lecture on hygiene to the inmates of the sanatorium, endeavouring thus to instil ideas concerning the importance of good food, suitable clothing, and properly ventilated houses into the minds of those under her care, and whom she hopes to restore to the duties of ordinary everyday life. The patients eagerly look forward to these lectures, and themselves become enthusiastic advocates of the treatment they are undergoing, and active missionaries of hygienic righteousness. Such an excellent educational procedure might be adopted with advantage in other sanatoria.

The terms are very moderate—2½ guineas a week, the same being charged for children as for adults; and bed-room fires are the only extra.

Rudwick is twenty-nine miles from London on the Horsham and Guildford line of the L.B.S.C.R., and there is a convenient train service from Waterloo.
Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, NOVEMBER 27TH, 1903.

DR. FREDERICK TAYLOR, President, in the Chair.

Mr. F. C. WALLIS described a case of CHRONIC INTUSSUSCEPTION TREATED BY INTESTINAL RESECTION, illustrated by the epidiascope. The patient was a healthy married woman, aged 32, who had been subject to attacks of pain in the abdomen on and off for two years. She was admitted into Charing Cross Hospital in one of these attacks, which was very acute, being accompanied by vomiting. There was no melena, nor could any tumour be felt. As her condition became worse it was deemed advisable to perform laparotomy, which was accordingly done on April 25th, 1903. When anaesthetised, the patient was found to have a considerable tumour in the abdomen, and on opening the abdomen it was seen to consist of a large amount of intussuscepted small intestine, which it was impossible to reduce. The entire portion of bowel affected—42 inches in length—was removed, and the two ends were joined by a Murphy's button. Everything went well until about three weeks after the operation, when the attacks of colicky pain began. These attacks were due to the Murphy's button, which was seen by means of the X-rays to be somewhere in the region of the ileo-cecal valve. The button was removed by a second incision, and the patient made an uninterrupted recovery, and has been in the best of health since. At the apex of the intussuscepted portion was a perforation evidently due in the first instance to some thrombosis. The main points of interest in the case were the length of time during which the patient suffered, her previous good health, the great amount of small intestine removed, the fact that no tumour could be felt per abdomen until she was anaesthetised, and that no exciting cause, such as a growth, could be found.

Mr. A. E. BARKER agreed that the perforation was no doubt due to interference with the blood supply, and emphasised the danger of perforation which might occur when such thrombosed portions were returned into the abdomen at the time of the operation. He was inclined to consider that enteroctomy could be done by simple suture as effectually as by any special mechanical appliance, and, moreover, one had a feeling of greater security. He also mentioned the importance of getting well above the intussuscepted portion when performing resection.

Mr. BRUCE CLARKE further insisted upon the peril of getting into a very unhealthy bowel. He thought as time went on that even the Murphy's button would be superseded by the operator's fingers.

Mr. WALLIS, in replying, agreed that the simpler the methods adopted were, the better, but in this case, where time was a great object, he felt more confidence in employing the Murphy's button.

The President then narrated TWO CASES OF LYMPHOCYTHEMIA (LYMPHATIC LEUKEMIA).

(1) A boy, aged 16, first complained of pains in the legs, thirst, and yawning. Six weeks later he was found to have enlargement of the left parotid gland, dulness over the upper part of the sternum, a deep-seated tumour in the left flank, but no enlargement of the lymphatics of the cervical glands. Two weeks later he was admitted into Guy's Hospital with enlargement of both parotid and submaxillary glands of the liver, and of the left kidney. A blood count showed 15,000 leucocytes per c.m.m., of which 70% were lymphocytes. A few days later the parotid swellings had increased, some lymphatic glands close by had enlarged, but there was no general increase in the size of the cervical glands, or those in the axillary or groin region. Each lacrymal gland was felt as a hard mass between the orbital ridge and the eyeball. The leucocytes increased to 50,000, and a differential blood count gave small lymphocytes 94, large lymphocytes 3, polymorphonuclears 2, eosinophiles 5. Haemorrhages from the mucous membranes appeared, and he died a month after admission. The post-mortem examination showed enlargement of the above-mentioned glands, also of the thymus, spleen and kidneys. Microscopically, the enlarged organs were densely packed with lymphocytes.

(2) A girl, aged 14, was seen on January 14th. Six weeks previously she had had pains in the limbs and a raised temperature. The mammary glands had been noticed to be enlarging. A fortnight ago her eyes became prominent, and two days after the feet swelled. She was pale, dyspnoic, and presented oedema of the eyelids. The salivary glands were enlarged; the mammary were enlarged, hard and nodulated. The liver reached one inch below the umbilicus. The edge of the spleen could just be felt. The lymphatic glands in the axilla and groins were not specially enlarged. A blood test showed an extraordinary excess of leucocytes, of which 95% were small lymphocytes. She died on February 21st, after the onset of ascites, epistaxis and uterine hemorrhage.

Dr. TAYLOR pointed out the rapid course of both these cases, and said that the enlargement of the mammary and the thymus were unusual features. The relatively small size of the lymphatic glands suggested to him that these organs were not primarily affected. He thought that the condition of the bone-marrow was in these cases, and mentioned a case of a child in which the bone-marrow was of a bright crimson colour. He regarded the subcutaneous and intestinal lymphatic deposits on the face and intestines, which sometimes occurred, as a matter of accident.

Dr. PARKES WEBER suggested that the bone marrow might be the origin of the lymphocytes, after all. He said that in every case of lymphatic leukemia in which the bone-marrow had been examined it was affected, and often presented the so-called "puriform" change—a term to which he objected. There was also at least one case on record in which the bone-marrow was the only leucocyte-forming tissue affected. He regarded these cells as really undifferentiated myelocytes.

Dr. PIERS said that in one case which he had examined the bone-marrow was crowded with lymphocyte cells.

Dr. TAYLOR, in replying, regretted that an examination of the bone-marrow was not made in his cases, and commented that differences in histological study were noted by Bradford and Shaw in that in the former the majority of the cells were small lymphocytes.

Mr. LAWRIE H. McGAVIN read notes of a case of POST OPERATIVE HERNIA TREATED BY THE INTRODUCTION OF A SILVER WIRE INTO THE HERNIA環.

The patient (who was also exhibited), a woman, aged 47, had undergone an operation fifteen years previously, for the removal of a uterine fibroid, and had developed a central hernia at the site of the old operation of such dimensions that the chances of obtaining a permanent cure by the usual surgical procedure were of the slightest. A silver wire filigree was therefore introduced between the muscles and the peritoneum, after the method suggested and practised by Willard Barker, measuring five inches by two and a half. The skin incision was closed by interrupted silk-silkworm sutures, and a firm abdominal binder applied. Both superficial and deep sutures were removed on the tenth day, and the patient left the hospital at the end of three weeks. Since the operation the patient had been well and comfortable in every respect, and was performing her duties without the aid of an abdominal support of any kind. The site of the cervix was somewhat depressed and a firm area marking the position of the filigree. The wire employed was of No. 7 gauge.

Mr. BRUCE CLARKE asked for further details regarding the manner in which the filigree was fixed.

Mr. A. E. BARKER congratulated Mr. McGavin upon the successful issue of his case and for bringing it before the Society. For his own part, he had been in the
GERMANY.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, November 17th, 1903.

RUSHTON PARKER, B.S., F.R.C.S., President, in the Chair.

DR. ALEXANDER showed a patient from whom he had removed the breast some time before. On admission, operative interference was apparently hopeless, as the tumour was adherent to the subjacent structures, ulcerating, and very foul. After the free application of crocin to the growth, and the administration of thyroid tablets, the tumour lost its hold on the deep tissues, and was removed by two operations. The microscope showed the growth to be adenocarcinoma. The question whether or whether the thyroid tablets, or some toxin from the septic condition, was the factor in the change.

Mr. F. T. PAUL and the President thought the improvement was brought about by toxic products derived from the septic infection.

Dr. Grünbaum spoke.

Dr. Alexander also showed a double uterus, adherent to each other only at the cervix. Each uterus had a distinct os and canal, one Fallopian tube, and one ovary. The formation of the organs was evidently due to absence of coalescence of Müller's ducts. The organ was removed for adenocarcinoma of the cervix; the postoperative uterine swelling was thought to be fibroid. The patient was a three-para. During the first two pregnancies she had amenorrhoea; in the third she menstruated till within two days of the birth of the child.

Dr. Briggs spoke, and Dr. Alexander replied.

Mr. R. H. JAMIN read a short paper on "Paralysis of the (Left) Third Nerve, with Blindness on the Same Side," due to a retrolubar neuritis. After a discussion of the etiology, Mr. Hamilton held it to be due to periostitis of the sphenoid, probably rheumatic in nature. The patient, a girl, 20, was shown.

Mr. Richard Williams had seen two or three similar cases, in which he had diagnosed periostitis at the base of the orbit. The patient had been subjected under the use of mercury and iodide of potassium alternately. The prognosis depended upon the rapidity with which the patient was brought under the influence of mercury.

Dr. Grossmann thought the etiology was generally obscure, unless traumatic. Prognosis was even more uncertain. The case he had shown on March 19th this year, though mercury and iodide had been freely given, still showed paralysis when seen a fortnight ago.

In his reply, Mr. Hamilton said his patient was improving under iodide and salicylate.

Dr. John Hay read a paper on "Pneumonia.

It was based on the observation and notes of 150 cases. Of these 150 cases, 21 were admitted moribund, or died within twenty-four hours of admission. After eliminating these, there was a death-rate of 31 per cent. Among of procedure occupied. It was admitted in 65 of the 150 cases, and of these 65, 37 died. After discussing certain physical signs, and some points in the physical examination, he dealt with the question of cause of strain and the effect of the onset of hepatisation, the toxæmia, the temperature, delirium, and struggling on the heart; he emphasised the far greater importance of the condition of the myocardium on the prognosis than the existence of valvular disease, and brought forward numerous cases in support of this view. The signs of cardiac failure were then discussed, with special emphasis being laid on the importance of careful definition of the deep cardiac dulness. He pointed out the extreme gravity of the prognosis in cases where an irregularity of the pulse was present before the lungs were affected, excepting in the aged or in those cases where there is marked mitral stenosis. The causes and treatment of sleeplessness, delirium with struggling, and flatulent distension of the belly were discussed, with the indications and contra-indications for the administration of morphia.

Dr. Hay was of opinion that the value of alcohol in the treatment of pneumonia was much over-rated owing to a misconception of its therapeutic action. It was of use in order to counteract any contraction of the peripheral vessels, such as occurs during the initial rigor, or as a narcotic and also during convalescence; but he held that the consensus of scientific opinion was opposed to the view that in its specific action it was a cardiac stimulant. He gave the results of the treatment of 47 patients treated throughout without alcohol, as compared with 103 who received it when the orthodox indications for its use arose. The patients in each class were, so far as it was possible, of a similar type, and yet after eliminating those admitted dying from both classes the mortality in Class I was 21 4 per cent. as compared with 36 4 per cent. in Class II, the average age in each class being about 35. The action and value of digitalis, strychnine, caffeine, and ammonium carbonate were discussed, and the treatment by the application of ice-bags to the abdomen referred to.

Dr. Nathan Raw would lay great stress upon the severity of the infection when considering the death-rate under any particular form of treatment. At times the severity was such that practically no treatment was successful; at other times the majority would recover. In an intermediate class much could be done, and his practice had been not to spare the use of alcohol when the symptoms appeared to demand it. He must look forward to the discovery of a direct antidote to the pneumonic poison.

Dr. W. Carter said there were only two periods in any case of acute pneumonia when he would like to use opium, viz., at the onset and certainly never later than the second or third day if the nervous centres were markedly affected, and at the very end of the disease, when the critical fall of temperature was followed by active delirium. In the latter case, though the physical signs were not much altered, the vital relations of the patient were such that a timely dose of opium was of the utmost value.

Dr. Albert E. Davis' routine practice was ammonium carbonate and six ounces of brandy per day. The death-rate was 10 per cent. in the last eighteen years. He deprecated the use of opium in any form at any period of the disease.

GERMANY.

[From our own correspondent.]

Berlin, November 28th, 1903.

At the Medical Society, HR. Brat showed a case of Tumour of the Pancreas, which he had had under observation since June last. The patient was taken ill in January with pain and vomiting. There was then a tumour the size of an apple between the umbilicus and the ensiform cartilage, which had gradually increased in size, and was now as large as a man's head. The stomach lay in front of the tumour, which was movable, and the colon behind it. He looked upon the tumour as a non-malignant one, in which hemorrhage had taken place.

HR. Finnes showed a Carcinomatous Masses that he had removed per vaginam, under the belief
that they were an ovarian cystoma. They grew from the meso-colon and appendices epiploicae. Six years ago the patient had been operated on for carcinoma of the mamma.

At the Free Society of Surgeons Hr. Borchardt brought forward a case of

**GUNSHOT WOUND OF THE PANCREAS.**

A woman who had attempted suicide with a revolver a few hours before was brought into the Royal Klinik in a state of the highest nervous excitement. She was extraordinarily pale, but had no strong, quiet, and regular pulse. The entrance wound was in the epigastrium, to the left of the middle line. There was left-sided pneumothorax. When he saw the patient an hour later the expression was still the same, but she had vomited mucoid material twice in the interval, but without any blood; the abdomen was also tender. Laparotomy was performed, and about half a litre of blood was come upon. The patient collapsed, but rallied quickly. There was an opening into the left lobe of the liver, and moderate hemorrhage from both exit and entrance openings; the hemorrhage was assisted by deep sutures. The hemorrhage from the gastro-hepatic ligament, which was shot through, caused more difficulty, but this was at last arrested by acupuncture and ligatures. As the speaker again looked over things he found free hemorrhage into the small pelvis, so that the intestines lying there were swimming in blood. On raising the stomach frightful hemorrhage took place from behind it to the left, and gauze and sponge were freely packed into the upper part of the abdomen. The patient now again collapsed. From the longitudinal incision a cross incision was made towards the left. A channel was now seen in the tail of the pancreas from which a little blood was flowing. The pancreas wound was sutured, and when the tampoups were pulled out it was seen that the same. But the vessels were torn and bleeding freely. The bleeding was arrested by stitching around. The abdominal wound was now closed so far as the necessity of an opening for removing tampons, etc., would permit. The patient rallied after free infusion of saline fluid, but recovered slowly, the progress being interrupted by a subphrenic abscess, biliary fistula and a double pleurisy.

The spleen, in spite of the ligature of its afferent vessels, did not become necrotic, there being anastomosis sufficient for its nourishment.

The danger of injury to the pancreas did not lie in the hemorrhage, but in the outflow of fat-splitting enzymes, which caused necrosis of fatty tissues that led to necrosis of the pancreas and peritonitis.

In penetrating gunshot wounds of the abdomen, for which laparotony should always be performed, one should not be content to examine the stomach and intestines only, but should always inspect the pancreas. Nothing but extensive tamponade of the surrounding parts would protect the abdomen from the fatal exit of pancreatic ferment.

Hr. Lexer brought forward a case of

**TUMOUR OF THE BLADDER, ONE OF PARAFFIN TESTICLE, AND CASES OF SKIN GRAFTING.**

A man, aged 59, had noticed, since the commencement of the year, a tumour in the abdomen, which caused a feeling of weight in the body, sometimes desire to micturate and to stool, but no special pain. A large tumour was found, before which lay the bladder; the tumour was tolerably movable. It was believed to be a myoma, but before the operation it could not be made out whether it sprang from the bladder or the rectum. Laparotomy showed that it grew from the bladder, and that it was pedunculated, with a broad attachment. A piece of bladder mucous membrane had to be removed in extirpating the tumour. The wound was closed by suture. The patient recovered.

The tumour, which was the size of a man’s head, was a myo-sarcoma.

He then showed paraffin testicles removed by him on account of the inconvenience they caused by their weight. He then spoke on unstalked skin flaps, the employment of which for plastic purposes had a wide range, especially for facial defects, and which gave very much better results than Thiersch’s transplants. If the flaps lay two to three days without reaction, they bore infection. A child got measles on the third day after operation, a man suffering from recurring erysipelas got the like at the same period; in both cases the healing in of the flaps was not in the least interfered with.

Hr. Trendenberg showed a preparation from a man who had Bottini’s operation performed twenty-two months previously. The preparation consisted of the bladder and urethra of the man, who had suffered from enlarged prostate. The parts showed that the operation had been successful both at the time and to the end of the patient’s life.

**Austria.**

[FROM OUR OWN CORRESPONDENT.]

**VIENNA, November 28th, 1903.**

**UTERINE CARCINOMA.**

At the Prague meeting Hausmann introduced the subject of carcinoma of the uterus by a description of the best methods of removing the morbid growths. He avers with great confidence that the disease is perfectly curable when properly treated. If the uterus be free and movable from the parametrium with infiltrated glands the latter must be cleared out carefully with the uterine organ. To do this successfully the operation must be laparotomy, by which you can obtain a clear view of the entire surroundings.

This operation may seem momentous for such a hopeless undertaking, but will be found successful and less dangerous than half measures for its relief. Early diagnosis means early operation, which in every case will prove successful.

**RAPID DILATATION OF THE UTERUS.**

Ostricil gave a history of four cases which he had treated by means of Bosil’s instrument for dilating the uterus. In one of the cases the patient was attacked with tetania uteiri, due to the decomposition of the contents of the uterus. This was associated with fever.

In the other three cases fits of eclampsia preceded the operation. The first of these was a primipara who had had four very severe fits that led to the use of the instrument to dilate the organ. The cervix was rapidly dilated 3½ centimetres through which one finger could be passed and both children delivered alive, but the mother died the following day.

The next was also a primipara, aged 16, who had had five fits with severe headache and amaurosis. The cervix was speedily dilated to admit the finger; in sixty-five minutes the uterus was fully dilated and the child delivered with instruments.

This case is interesting in the fact that albumin was observed in the urine three days after the confinement and then disappeared. Eight days after, however, she had a severe fit with no recurrence of the albumin, although the urine was normal in constituents and sufficient in quantity.

The last case was also a primipara, aged 20, with repeated attacks. The cervix was perfectly cleared. Bosil’s instrument was applied, but was speedily
THE OPERATING THEATRES.

THE MEDICAL PRESS. 615

THE OPERATING THEATRES.

ROYAL FREE HOSPITAL.

EPITHELIOMA OF FLOOR OF MOUTH.—Mr. T. P. Legg operated on a man, aged 65, who had been admitted for an epithelioma of the floor of the mouth. The patient had stated that six months previously he had noticed a small sore place on the left side of the frenum lingue; this steadily increased in size till it became as large as half a crown. The ulcer at the time of operation extended from the alveolar margin of the lower jaw as far back as the frenum lingue. The edges of the ulcer were everted, hard and raised, the base was nodular and indented. The submaxillae glands on the left side were hard and enlarged. The submental glands were not apparently enlarged, and there were no other enlarged glands in the neck. The mucous membrane on the inferior aspect of the tongue was involved in the growth, which, however, did not appear to infiltrate the muscles of the tongue, all the movements of the latter being quite free. The patient's general health was in every way satisfactory, and the operation was performed in the following manner:—

A horizontal curved incision was made in the left inferior submaxillary region and extended across the middle line into the right submaxillary region. The left submaxillary salivary gland and the submaxillary lymphatic glands on the left side, together with the submental glands on both sides of the neck, were removed with the fat and fascia. A median incision was then made through the lower lip and soft tissues covering the jaw, the inferior end of this incision meeting the former one; the flaps so marked out were dissected off from the lower jaw on each side. A stitch was passed through the tip of the tongue to hold it forwards; the upper part of the ramus of the jaw was then sawn through on the right side in the position of the first bicuspid tooth and on the left side in the position of the second bicuspid. A third saw-cut was next made parallel to the inferior margin of the ramus and joining the two former saw-cuts. About a fourth of an inch of the arch of the jaw was thus left intact. The tongue, with the floor of the mouth and the detached piece of jaw, were then pulled well forwards, the growth, together with the whole of the genio-hyoid, a part of the genio-glossus, the anterior belly of the digastric, and the mylo-hyoid muscles with the detached piece of jaw were removed in one mass. A wide margin of apparently healthy tissue was left round the growth. The raw area on the under aspect of the tongue was covered in by bringing together the cut edges of the mucous membrane with three purse-stringing sutures. Ligatures were applied to any bleeding vessels, and two drainage-tubes were put into the wound, the posterior one leading from the wound in the neck to the cavity of the mouth, which could not be completely shut off from the external wound. The whole of the external wound was finally closed by interrupted sutures. Mr. Legg remarked that the only hope of curing patients with epithelioma of the mouth was early and complete operation. Two points in this operation were, he thought, worth noticing. First, the method of dealing with the jaw. In a large number of cases it is necessary to remove the whole-thickness of the horizontal ramus, and this leads to very considerable deformity. In the present patient, as only the alveolar margin on the left side was slightly involved, it was, he said, worth while to preserve the shape of the jaw in adopting the method of removal of the glands; in this case they were slightly enlarged, and as the surgeon can never tell that glands which cannot be felt to be enlarged are not affected by epitheliomatous cells, therefore the free removal of the lymphatic glands was, he considered, essential; at the same time the submaxillary salivary gland should also be removed, as it contains in its capsule lymphatic glands which are frequently involved. He pointed out that in all these extensive operations in the mouth

dilated to two centimetres, and finally she was delivered without any mishap.

This method of rapidly dilating the uterus is contra-indicated in placenta praevia.

Jerie said that he had used this instrument of Bossi's three times on mothers with eclampsia from twins with success, for the dilatation of the uterus being achieved, pains were certainly increased, and he would not recommend the instrument except on such occasions as eclampsia or such-like urgent necessity.

NEURITIS NERVII AXILLARIUS.

Tuma brought forward a female, aged 32, who, after the third confinement was attacked with neuritis of the axillary nerve and paralysis and atrophy of the deltoid muscle on the left side. Shortly after the confinement she was seized with a rigor and a rapid rise of temperature. Five days after this attack she had a severe pain in the left shoulder extending down to the elbow with paresis of the deltoid, which six weeks later became quite paralysed and insensible to the faradic stimuli, though the feeling of sensibility was still normal. After this course of electrotherapy she greatly improved.

He showed another case of a labourer, aged 39, with contractions of the left scaleni media, sterno-pleuro-
domastoid and others without any cause. The head was fixed towards the left and backwards.

Pelhan related a similar condition in a woman, aged 62, who had a fall on the left arm which dislocated the left shoulder. After the dislocation was replaced the deltoid was found to be paralysed and insensible to electric stimuli. This was followed by atrophy, anaesthesia, and hyperalgiesia of the skin. In this we have another example of the nerve axillaris alone being affected from the whole cervico-brachial plexus.

Sebor related another similar case to the latter from a fall also.

SPASTIC PSEUDO-PARESIS WITH TREMOR.

Pelhan showed a man, aged 33, with chronic alcoholism and multiple peripheral neuritis. The symptoms were somewhat peculiar. In the horizontal position nothing abnormal could be observed, but immediately he made an effort to rise or stand up the movement in the muscles was extreme with a rapid rhythmic tremor. In progression the tremor was still more excessive, affecting the whole body. Meeting anyone going up a stair, or crossing a string or cord, made him very ill. On entering a bath even when the water only reached the knee the whole tremor would cease. Under these conditions the patient could stand on one leg, which would be impossible under any other condition. He could even walk backwards and blindfolded in the bath! The reflex was not increased. These complex symptoms were first observed and described by Nonne and Fürstenr, and were described as astasia-abasia and dystasia. The present case differs from those on record by being non-traumatic, although the patient may be designated a drunkard and the offspring of a drunken family, with syphilis.

URTICARIA AND EPIDERMOLYSIS BULLOSA.

Samberger exhibited a boy, aged 13, with urticaria bullosa and epidermolysis bullosa which had appeared without any cause. It was a typical form of urticaria gyrate passing rapidly into pustules. Where the skin was abraded or rubbed the pustules formed at once. Large quantities of indican were present in the urine.
made a sympathetic allusion, it will be necessary to appoint another inspector for the final examinations of the Scottish Universities. In some instances, where the power of inspection is vested in the assistant examiners appointed by the Council, as in the case of the Apothecaries' Hall of Dublin, an occasional visitation and report from an inspector specially appointed will probably meet all the requirements of the Council.

A matter which more directly affects the common interests of the profession is the possibility of instituting in England a general system of leaving examinations for secondary schools, which might be accepted in place of the preliminary examinations that are now required for admission to the various professional bodies. The Board of Education has communicated with the Council upon the matter, and proposes to hold a conference at which representatives of the Council are invited to attend and discuss with the Consultative Committee the ways and means by which such a plan might be rendered feasible and desirable. There can be no doubt that a certain standard of uniformity with regard to general education must sooner or later be laid down, and the higher the standard is raised, within limits, the greater will the reaction be for good upon the medical profession at large.

The examinations of the Educational Institute of Scotland, conducted in this way, have been adjudged by the Education Committee of the General Council to be so satisfactory that it is believed that during the forthcoming year these examinations will have attained in every respect the standard desired by the Council. The multiplicity of professional examinations for qualifying degrees or diplomas is undesirable, but, at the present time, an unavoidable arrangement. The injurious effects of the multiplicity of general preliminary examinations are even more far-reaching. It is, of course, not to be supposed that the standard of these preliminary examinations should attain to that of, say, the London matriculation, but, regarded as an introduction in arts for the wider mental training necessary for students of a learned profession, it is most desirable that these should include Latin and at least one science. The whole scheme is yet immature, therefore it is impossible to forecast results until more definite projects have been established, but we feel sure that such a conference as the one about to take place can hardly fail in placing the subject of preliminary medical education upon a more fixed basis than it has hitherto been.

The nature of the returns from the Army, Navy, and Indian Medical Departments, which were accepted by the Council on its first day of business, afford ground for satisfaction that these important Services are gradually attracting more and better men, the number of candidates in the last competitions considerably exceeding the vacancies. Another point of some interest is the paucity of men holding University degrees, the most general qualification being that of the English Conjoint Board. The question of the

THE POOR-LAW MEDICAL SERVICE.

The recent address of Sir Lambert H. Ormsby on the Poor-law Service as a field for medical practitioners, has been the subject of much comment. As was his duty as President of the Royal College of Surgeons in Ireland, when addressing students who were on the threshold of the medical profession, Sir Lambert H. Ormsby pointed out some of the much-needed reforms that should be effected in the Poor-law Service to make it accord with modern requirements of medical service. One of the reforms advocated was a change in the manner of appointment, the suggestion being that election by the guardians of union medical officers should be replaced by election, made after examination, by an examining board, and the appointment should be secured by merit alone. The recommendation of selection by examination was sharply criticised by Mr. M'Ardele, who endeavoured to make the best case possible against it. He considered that the proposal involved the doing away with the elected guardians in the matter, tended to centralisation, took from the ratepayer any voice in the selection of the medical officer he paid, and was contrary to the spirit of the age. But these objections do not touch the main question at all, which is that the sick poor be provided with suitable medical officers. The sick poor entitled to the services of the medical officer—the cottar labourer and his family—have practically no voice in the selection of the medical officer. The selection is made by the small farmers, and almost invariably made on political or religious grounds. This method of election has inflicted a terrible injustice on the sick poor who call for medicine and advice, and are over-dosed with politics in every parish in Ireland. The essential requirement for the office is medical knowledge, and this is the one thing on which boards of guardians, with a few honourable exceptions, put least stress. This fact came to be so plain that some candidates have been known to canvas guardians on the grounds of religion and politics, and to produce as testimonials letters from clergymen and copies of cards of membership of political organisations. Such conduct showed to all men that the boards of guardians were not considering the poor and were not loyal to the spirit of the trust committed to them. So far we have spoken of the injury the action of the guardians inflicted on the sick; but what must be the effect of such conduct on young professional men who have sought to attain distinction in their profession by diligent study, and find that membership of some political club counts more than all academic honours in securing an appointment? If the guardians have proved themselves unworthy of the trust committed to them, can it be argued that they should be further trusted? Other critics have, in interviews with the representative of a lay journal, found fault with the advice that the Poor-law Service should be shunned, and apply to the act the opprobrious word "boycott." There are many paths to distinction for the medical practitioner besides the Poor-law Service, and to recommend him to take any one of them other than the Poor-law Service is not boycotting the latter. It is unjust to the medical profession and to those who have taken an active interest in promoting the movement of the medical associations for the
improvement of the Poor-law Service to brand their conduct as boycotting. It is quite legal, and oftentimes right, that men combine to secure what they consider fair remuneration for their services; and it is often advisable that young men entering on appointments should be shown the difference between the losses and the net income to be gained by the undertaking. The question on which they are about to enter. Sir Lambert Ormsby and the Irish Medical Association have not done more than this, and their duty to the profession and the public required that they should not do less.

INSANITY IN IRELAND.

The important meeting held at the 25th ult., at the Richmond Lunatic Asylum, of the representatives of the Irish Districts Committees had before it questions of the utmost importance both from a financial and a social point of view. The burden of local taxation has reached a point that makes it oppressive on the people and very seriously interferes with our industries. A very large percentage of this is swollen up by the expenses incurred in the care of the insane. The number of the insane is increasing, every district lunatic asylum in the country is overcrowded, and demands are made on the taxpayer for auxiliary asylums, and repairs to the existing buildings. For years past the Medical Press has been urging that an adoption of the Continental method of treatment might be adopted for all such cases as were considered suitable for boarding out, and the existing asylums would, by this means, relieved of their surplus number of inmates, to the benefit of those remaining in the asylum and those boarded out, and to the great relief of the ratepayers. We have more than once described the Ghent method, that of Antwerp, where boarding out of lunatics has been practised for eight hundred years, having been commenced soon after the death of Dymphna, the fugitive Irish princess, who became the patron saint of the insane. The reputation of the shrine of this half barren stretch of moorland near Ghel brought many devotees, some of whom arrived late for the saint's day and, wishing to avoid such a misfortune again, they remained as boarders with the families of the neighbourhood, paying their host in money and labour. Thus for centuries the district between Herentals and Moll was cultivated in great part by the insane, who lived amongst the people, talking to them and bearing their care. The work were Duke in York, or Pinel in Paris commenced their humane crusade. That absence of restraint and occupation was beneficial in many cases, and that in many more the insane were not, when patiently dealt with, dangerous, was demonstrated century after century in Ghel to all nations, without producing any effect until M. Pontecoulant was appointed by Napoleon Prefect of the Department of the Dyle. He noticed the success of the domestic treatment in Ghel, and had inmates of the City of Brussels Asylum removed to the country. His example was followed by the authorities of other asylums, and Ghel received official recognition. In this country the question of the better care of the insane. The reforms commenced and culminated in the following system, which is worth careful consideration, as it is attended with good results from a medical point of view, is economical, and puts much of the money expended into the pockets of the small farmers. The asylum of the town, for Ghel has now a population considerably over 15,000, is divided into two portions, for each of which a doctor and his assistant (a fully qualified medical practitioner) are appointed, with four surveillants, all being subordinate to the medical director of the colony. Patients on arrival enter the asylum, where for five days they are under observation. If at the end of five days it is judged advisable for them to enter a private family, great care is exercised in choosing a home for them. The local keepers are people of good character, and the sanitary condition of their houses is closely inspected. The nearest being authorised to enter them at all times of the day or night. The cost of maintenance varies from £10 to £100, according to the accommodation given. Such a system could not be adopted in its entirety in Ireland; but it is a step in the right direction. An increasing number of young people are being congregated under supervision at farm work, weaving, carpet-making, or other suitable employment — the profit to go to the upkeep of the colony. A more difficult question—the cause of the increase of insanity in the country—naturally engaged the attention of many of those present, and it is regretted that no satisfactory explanation has yet been found. The theory that it is largely due to emigration is put forward by those who do not reflect on the fact that the percentage of lunacy is not highest in the counties that have suffered most from emigration. Again in 1861 the ratio was 1 in 851, in 1871 it was 1 in 541, and in 1901 it was 1 in 225. From 1849 to 1859 there was an exodus of the people to the States and, if emigration can be looked on as the cause, even a principal cause of lunacy, it is strange that the ratio of lunacy is so much less than 1901—less than the half—when the rate of emigration was for thirty years so much less. An analogous increase in lunacy to the increase in Ireland took place in the Southern States of the U.S.A. after the Civil War. In 1861 there were no negro lunatics in the cotton States. To-day the negro suffers almost as much as the Irish. Now no negro emigrated. In Belgium, where emigration is unknown, or almost so, lunacy is on the increase. Drink as a cause may be considered under two heads—pure drinks, as good ales and matured whiskies, and the doctored concoctions that are manufactured from Continental spirits, distilled from treacle, potatoes, and bad rice. Such compounds are capable of producing mental derangement as are cocaine, morphia, mescal, and other drugs. But in the old poineen days in Ireland there was more alcohol consumed a head than there is to-day. From the youngest to the oldest—men and women and children—all drank poineen. And it is a remarkable fact that until Ireland was made sober by Father Mathew the ratio of lunacy was very low indeed. We are inclined to the opinion that the strain and anxiety of mind that the Irish man suffered from during the past thirty years of the present war was a great factor in unbalancing his mind and we are hopeful of the future now that the long strife has practically come to a close.

THE COUNTY WEXFORD BRANCH OF THE IRISH MEDICAL ASSOCIATION.

At the large and representative meeting of the County Wexford Branch of the Irish Medical Association, held in Enniscorthy on the 11th ult., under the presidency of Dr. G. E. J. Greene, J.P., the members expressed their determination to oppose to the last the proposed amalgamation of dispensary districts, and announced their intention of adhering to their former resolution, threatening to resign in a body rather than submit to the I.L.G.B. in this matter. We have more than once pointed out that if the I.L.G.B. succeeded in their rearrangement scheme, to use the term of the officials, the objects that the medical officers strive for would be unattainable. Any increase in the size of existing districts, with very few exceptions, would necessitate the discontinuance of private practice, and as a consequence it would bring into the district a private practitioner; both would suffer, the private practice would not pay more than a bare subsistence, and the union medical officers would find his increased remuneration so low as to render his work unprofitable. An ordinary dispensary district taxes the strength of a horse to its utmost. Increase the area of the district and the number of patients to be visited, and a second horse becomes a necessity, and with it increased expenses. The Wexford branch has
rightly decided to call on the members to resign if the amalgamation scheme is insisted on; and we do not hesitate to say that if it becomes necessary so to act the whole body of the medical profession will support us. We believe that under such circumstances there would not be found a candidate for either a temporary or permanent Poor-law medical appointment in Wexford. The members of the profession recognise that the amalgamation scheme has as its object the defeat of the Irish Medical Association’s endeavour to improve the pay and conditions of the Poor-law Service; and the only way open to the union medical officers to frustrate the action of the I.M.A. in the matter is to resign. It is the only legitimate reply; it is called for in the interests of the profession, and, above all, it is demanded in the interests of the poor. An increase of the area of a dispensary district means a lessened amount of attendance in sickness, and this diminution is out of all proportion to the addition as measured by acres. As we have before said, an increase of area of a dispensary district is a keeping of the let-alone and a breaking of the spirit of the Medical Charities Act.

Irish Unions.

MANORHAMILTON UNION.

On Wednesday, the 18th ult., the I.L.G.B. inspector held a sworn inquiry at Manorhamilton into the charges brought by Dr. O’Flynn against the district midwife, Mrs. Kilkenny. The charges include mutilation of registers, disappearance of drugs, the use of filthy and obscene language, and general bad behaviour. Mrs. Kilkenny brings a counter charge of receiving fees on a red ticket, of supplying drugs from the dispensary station to private patients, and of habitually being late at his dispensary against Dr. O’Flynn. After hearing the evidence of a number of witnesses, the proceedings were terminated. The decision of the Board will appear shortly.

BANBRIDGE UNION.

At the usual weekly meeting of the Banbridge Board of Guardians, held on Monday, the 9th ult., the guardians instructed the clerk to the union to issue advertisements for a medical officer for Banbridge dispensary district at £160 a year. This is an advance on the salary paid to the late Dr. Dobbin of £150 a year, but is as yet insufficient. The district is a large and populous one, of 14,599 inhabitants. There are two dispensary stations, and it is proposed to open a third at a distance of six miles from Banbridge town, the centre of the population.

ENNISCORTY UNION.

At the usual weekly meeting of the Enniscorthy Board of Guardians, held on Thursday, the 19th ult., Dr. Michael Delaney was elected medical officer at a salary of £130 a year. Clonmore dispensary district has an area of 35,282 statute acres, a population of 4,377. There are two dispensary stations. During 1902 there were 452 dispensary tickets and 164 visiting ones issued; the vaccination fees during the same time amounted to £6 2s. There is in addition the salary of £15 as medical officer of health. But, all told, the remuneration falls far short of £200, the minimum on which experience has shown a dispensary district can be worked. Perhaps Dr. Delaney will yet see the wisdom of following the course adopted by Dr. Griffiths, who resigned his post in the Shillelagh Union after a period of six months.

STROKETOWN UNION.

At the last meeting of the Strokestown Board of Guardians a letter was received from Mr. P. N. White, Sligo, enclosing a bill for £11 11s. for empty bottles. Dr. Duffy, who was present, stated that he had sent Mr. White four boxes of empties four months ago. One of the most annoying duties of a dispensary medical officer is in connection with empty bottles. The medicine contractor is bound to send for them and bring them away, but when this duty is irregularly done, bottles get lost and broken and trouble results. Some way out of the difficulty should be found.

MULLINGAR UNION.

At the usual weekly meeting of the Mullingar Board of Guardians, held on the 12th ult., a letter was read from Dr. Edward J. Timan, asking the guardians for his fee of £2 2s. for a consultation in the Killucan dispensary district. He had to travel twelve miles and afterwards assist the medical officer in a difficult operation, which had to be performed under many disadvantages. The demand for the fee, which was considered excessive—"£2 2s. is not the usual fee; it is £1 3s."—was made the text for a sermon by a Mr. Rowan, a member of the Board, who explained the action of the I.M.A. in the matter to the local doctors over Ireland who were taking part in this business was to put the guardians of unions in as ridiculous or idiotic a position as possible." It would be unnecessary to make any such move as Mr. Rowan suggests; the guardians effectively perform this duty. But Mr. Rowan’s disrespect is not confined to union medical officers. He describes the Dublin physicians as "thimbleriggers," who have some definite object in view, which he believes is unfriendly to the local guardians. We think that the worst enemies of the guardians are the small-minded, prejudiced members of the boards, who fail to see that their captious objections and constant cavilling at the reasonable demands of their medical officers and their inability to transact their ordinary business demonstrate to the country that they are entrusted with duties for the carrying out of which they constantly prove their unsuitability.

ARMAGH UNION.

At the usual weekly meeting of the Armagh Board of Guardians, held on Tuesday, the 24th ult., a letter was read from Dr. Gray in which he stated that he was unable to interpret the chemical terms of the analyst’s report. He could only help if the Board of Guardians would ask the analyst in plain terms whether a sample was, or was not, correct. We think that every analysis should state plainly the fact that the medical officer desires to know before a detailed account. Such a quantitative analysis is given in this case, and the Board should have the whole details of the quantitative examination.

A HUMANE RECOMMENDATION.

At a meeting of the Kilmallock Board of Guardians, held on the 21st ult., a letter was read from the I.L.B.G. recommending that the aged and infirm wards of the workhouse be heated during the winter months. No better or more humane suggestion could be made for the infirm poor. Every medical practitioner knows how trying it is on the feeble and aged to undress in a cold room and get into a cold bed. How often do we find that those of low vitality succumb to the chill that precedes morning. We sincerely hope that the recommendation of the I.L.B.G. will be adopted and the comfort of the aged poor be seen to without unnecessary delay.

LETTERKENNY UNION.

At the meeting of the Letterkenny Board of Guardians held on November 20th, Dr. T. Patterson appeared before the guardians and suggested that paid assistants be provided for the workhouse inmates. He detailed some of many evils attending on the help of pauper inmates, and it is satisfactory to know that the guardians took steps to carry out his suggestions.

IRISH POOR-LAW MEDICAL SERVICE.—Medical Officers, before applying for appointments in above service, should communicate with the Hon. Secretary of the Irish Medical Association, Royal College of Surgeons, Dublin.
Asylums.

YOUGHAL AUXILIARY ASYLUM.

At the monthly meeting of the joint committee of management of the Cork District Lunatic Asylum, held on Tuesday, the 20th ult., Dr. Woods, the medical superintendent, notified that "The works of Youghal auxiliary asylum have progressed satisfactorily during the month, and the heating and lighting is now completed, and practically the place would be fit for occupation early next month." At the same meeting, Alderman Walsh, a member of the joint committee, proposed, and Mr. J. J. Howard seconded, the following motion, of which notice had been given:—"That the previous resolution recommending the appointment of a visiting physician for the Youghal Auxiliary be rescinded, and that we appoint instead on that day a resident medical officer for the institution, in accordance with the unanimous opinion of the medical profession, as expressed in the public Press, and I will further move that the salary be fixed at £200 per annum." As might be expected, there was an unusually large attendance at this meeting, which was met by an amendment, moved by the Most Reverend Dr. Kelly, and seconded by Mr. O’Gorman, "That in order to uphold the dignity of this committee and prove its confidence in its own ability to regulate the affairs, we will consider Alderman Walsh’s resolution." The proposer of the amendment ridiculed the idea of adopting the opinion of the local medical practitioners of the city on the question, and declared that the committee would be paying Dr. Woods a very poor compliment indeed, if, passing his opinion, the committee were to take the opinion of a body who called themselves "the Medical Faculty of Cork." The reverend gentleman quite forgets that when this resolution was previously discussed by the committee, Dr. Woods, at the request of the committee, gave his opinion as strong as words could make it in favour of a resident medical officer, practically saying that the medical officer was unnecessary. It follows that as Dr. Woods and the medical practitioners of Cork are fully agreed on the question of a resident medical officer, the Most Reverend Dr. Kelly runs counter to all the professional opinion that has been given on the subject. The amendment was warmly supported by the Most Reverend Dr. Browne, who based his argument on the few cases of accidents or attempted homicides they heard of, quite ignoring that at the same meeting Dr. Woods had reported an attempted suicide of a male patient on the 3rd ult., "by cutting his throat with a piece of glass." What would happen in Youghal Auxiliary Asylum with no person present other than non-religious sisters, who have no medical training, even as nurses. It is but a few weeks since we reported a homicidal outbreak in a harmless lunatic in Sligo Workhouse, which endangered the life of the matron and of the visiting physician. The Most Reverend Dr. Browne has not heard of imbeciles being choked at meals, and as he has not heard of such an occurrence he disbelieves in it. Some nineteen medical gentlemen whose duty it is to make themselves familiar with such matters pledge themselves to the accuracy of the statement, and yet the Most Reverend Dr. Browne refuses to believe it. It is, however, well to remember that if the statement of those most competent to know were accepted, there was no chance of the amendment being carried. As it is, four hundred mentally diseased persons are to be huddled together without medical supervision other than a visit daily. The convents are to be closed, and the blame is laid on the non-religious sisterhood who are wholly ignorant of medical diseases.

CLONNEL ASYLUM.

The report of the Clonmel district lunatic asylum for the year ending December 31st, 1902, tells very plainly the great difficulties a resident medical superintendent has to contend with in trying to adapt an old building to modern requirements, and should be a most useful lesson to those now considering a modification of Poor-law unions that would leave a number of buildings suitable for auxiliary asylums. From the report of the inspector of lunatics, which is embodied in the annual one, we learn that the question of heated front corridors and the observation dormitory on the female side is under consideration. The erection of a mortuary and the enlargement of the male dining-room are to be carried out, if such an antiquated building warrants the outlay. Dr. F. P. Harvey, the resident medical superintendent, writes that the committee will soon be able to commence building. When the said buildings are finished it will be possible to remove the insanitary from the workhouses of the district. Like every other asylum in Ireland, the building is overcrowded. At the beginning of the year the inmates numbered 730, at the close of the year 712. During the year there were 173 patients admitted, of whom 53 were first admissions. It is a hopeful sign to find that 51 of those admitted were brought to the asylum within three months of the first symptoms of the disease. It shows that the patients’ friends recognise the value of treating the disease, and recognise that lunatics are to-day treated with kindness and skill. The mortality is affected by the overcrowding, which is equally injurious to the insane and sane, and if it was the highest ever recorded, a cent., in Clonmel, it would be disastrous. The non-religious sisters are directly traced to the overcrowded state of the wards. It is satisfactory to find, without diminishing the comforts of the patients, the expenditure a head has been reduced from £24 15s. 4d. to £23 1s. 3d. Dr. A. C. O’Sullivan, the bacteriologist, made an exhaustive analysis of the water, milk, and so forth. He condemns two of the sources of the water supply, and advises that Hunt’s milk supply should be stopped. Apart from the result of the examination given above, the extreme filth of the place and its surroundings render it impossible that the milk should be supplied in a pure condition." The report is a valuable record of how much a zealous medical superintendent may accomplish, even when handicapped with overcrowding in an antiquated building.

WATERFORD.

We regret to find that Dr. M. P. Coghlan was seriously injured a few days ago while riding home after attending a sick call. He was overtaken on the road by a motor car, which ran into his horse and cart. The driver of the car, thinking that, as the doctor was well on his own side of the road, he could by putting on a spurt rush past, made the attempt, just as the horse swerved round into the middle of the road. The motor car struck the animal, which is seriously injured, and Dr. Coghlan was thrown off and sustained severe injuries, which have necessitated his discontinuing his practice for some time.

DISPENSARY RECORDS.

At a recent meeting of the Armagh Board of Guardians a letter was read from the I.L.G.B. in reference to the examination of dispensary records. The Board will not sanction the guardians of the dispensary district examining the records at the dispensary station. The records must be brought to the dispensary and be there examined; but if the guardians, or the committee of the guardians delegated for the purpose, may select a suitable date, or suitable dates, in each month upon which to meet at the board-room for the discharge of the business set forth in article 10 of the dispensary rules."

THE SOCIETY OF APOTHECARIES.

It would be well for the public and the profession if the present system of qualifying for licenses to practise were in some way simplified by reducing the number of corporate bodies which are allowed to examine and grant licenses to candidates who present themselves for and pass their examinations. The friction referred to by the President of the College of Physicians at the recent dinner of the Apothecaries' Society as having existed between the College and the Society may, to some extent, have subsided; yet, from the nature of the case, these two corporate bodies must be more or less in antagonism, as they and the London University are the only licensing bodies in London. It is true that the University may be changing in such a way as to produce some effect on the Conjoint Board, for if their examinations are not very different, there is little doubt that the degree of the University and the right to the title of doctor would be preferred to the license of the Conjoint Board. The friction that Sir Selby Church alluded to was nothing more nor less than the unconcealed desire of the College of Physicians to exterminate the Society of Apothecaries; and there is no doubt, when it was seen that the Society could not amalgamate with some other body, as the Physicians did with the College of Surgeons, their fate was in a critical condition. When the Society, however, managed to get over the difficulty by arrangement with the Medical Council, and a surgical board was appointed to supply what was wanted to make the L.S.A. a full legal qualification, the hopes of the College began to subside, and the friction to disappear. Whatever credit is due to the Physicians for their part in this finale is of a very negative kind, and it would have been well if Sir Selby Church had recognised clearly what right the College had earned to the gratitude and consideration of the Society. One influence at work ought not to have passed unnoticed, namely, that the examiners appointed by the Society for the L.S.A. examination are all Fellows or Members of the College of Physicians; and as some are acquainted with the examinations, both of the Conjoint Diploma and of the Apothecaries, the College has apparently thought it wise to keep on good terms with the Society and reduce the friction to static indifference or passive toleration. The remarks of Mr. Tweedy at the dinner of the Society were sensible and show clearly that the practical surgeon has some sympathy with, and respect for, the work of the apothecary; and that the general practitioner is equally well qualified on the system of the Society as on that of the College. How matters will develop is not very clear, and we shall not be surprised to see some unexpected changes in the views entertained by the profession and those preparing for it on the question of the two licenses we have been considering.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

President Roosevelt has said that a philanthropist should be hard-headed and not too soft-hearted, and that every donor to a charitable cause more than doubles the value of his gift if he interests himself in seeing that it is properly applied. The easy benevolence of the charitable public has been a fruitful source of extravagance and unbusiness-like finance on the part of the hospitals, a condition of things which has often been the subject of comment and criticism, but for which, so far, no effective remedy has been forthcoming. When the Prince of Wales' Hospital Fund (as it was then called) rose out of the ashes of the projected Central Hospitals Board for London, it was hoped that a body would be formed which, by the power of the purse, would be able to exercise an effective control over the hospital authorities of the Metropolis. Surely no body ever had so fine an opportunity of doing this necessary, if ungrateful, task as had the Council of the Fund. The question naturally suggests itself: Have they risen to the occasion? That they have effected a good deal is certain, but it is because there is much that still remains to be done that some criticisms and suggestions may be offered. In the first place, it is surely desirable that a public body of that importance should tell the public what they have done and are doing. The annual report is terse, not to say jejune, and contains no reference to that most important branch of the work of the Fund, namely, the experiences of the visiting committees. Now, with all respect to the gentlemen, lay and medical, who give their services as visitors, we think that their work is inadequately performed unless it is supplemented by a written report of the conditions they find at each institution visited, giving in detail the financial, administrative, and medical aspects of their inspection. Moreover, these reports should be published. Doubtless this would add to the labours of the visitors and to the expense of producing the annual report; but the visitors should not offer their services unless they can do so ungrudgingly, and the extra expense of the report is money well invested. The people who give the large sums to the Fund are successful business men. They are accustomed to see that the money they handle is used to advantage, and it is a great deterrent to these subscriptions for uncertainty as to the efficiency of their disposal to prevail. The next point that attention may be called to is the desirability of a statement of the policy of the Distribution Committee in making their awards in each case, and of an indication as to how far the institutions are prepared to respond to the conditions and suggestions. We note that the sums allotted to the different hospitals are not proportionate either to the number of beds available nor to the income derived from ordinary sources. Now, we have no doubt that there are excellent reasons for the action of the Distribution Committee in each case, but, in fairness to the institutions and to the subscribers,
these reasons ought to be given. Some hospitals have applied for a grant and been refused. This places them in an invidious position. If they are badly managed or used for improper purposes, a great service would be done to the cause of charity if the facts were made known; if the refusal merely indicates that they are less in need of assistance than kindred institutions, a statement to this effect would clear them of the imputation that naturally rests upon them if silence is maintained. We fear that the mere small size of a hospital, apart from considerations of economy and probity of management and value of the work done therein, is made the excuse for denying a grant. Against this injustice we have again and again protested. Another fact on which light is urgently needed is the principle on which sums are allotted to extinguish debt. There has been a vast deal of financial immorality in the past management of charitable institutions; debt has been recklessly incurred on the ground that when it reaches a certain figure an appeal to the public will be justified. This perversion of trust—for it amounts to nothing else—deserves severe retribution, and it would be satisfactory to know that the committee of the King’s Hospital Fund sternly discountenances such reprehensible laxity. The extravagant, debt-laden hospital receives a fat grant, while the economical poverty-stricken institution is sent empty away. There are several objects which the Council of the Fund have in view that are quite admirable, and, on the other hand, some of their actions are puzzling; for instance, the refusal of a grant to the Frank James Memorial Home, and how it is they derive an income of £5,105 only from the £250,000 left by Mr. Lewis. What we want is more light, more definite information, both as to principle and actions. The Council of the Fund is now in an extremely strong position; they have the administration of a sum of £100,000 a year; they are trusted by the public, and they are honoured by the confidence of the King. They have a splendid opportunity of bringing the hospitals of London into line with the needs of the Metropolis, and of assuring the charitable donors that their gifts are producing the greatest benefit possible to those for whom they were intended. To serve these admirable results means hard work ungrudgingly performed. We should view with the greatest satisfaction a full and complete annual report on the lines we have indicated.

Notes on Current Topics.

The Petition in the Wyrley Cattle-Maiming Case.

The response to our Petition to the Home Secretary to institute an inquiry into the state of mind of the young solicitor, Edalji, recently convicted to seven years’ penal servitude for maiming cattle at Great Wyrley, has met with a gratifying response. A number of signatures have reached us from all parts of the United Kingdom, as will be seen by a reference to the list published elsewhere in our columns. No attempt has been made to obtain individual signatures, except in the case of four or five prominent medico-legal and alienist authorities, who have been approached. Considering the few days during which the Petition has been open for signature the result has been satisfactory, as proving a widespread interest on the part of medical men in the position assumed by THE MEDICAL PRESS AND CIRCULAR with regard to that petition. That Edalji may be altogether innocent is possible. With that aspect of the matter we are not here concerned. We maintain, however, that it is the duty of the medical profession, as a whole, to insist upon the desirability of a full and adequate inquiry into the state of mind and the consequent responsibility or irresponsibility of an educated man convicted of such brutal criminal atrocities as the purposeless maiming and killing of a number of domestic animals. We are informed on good authority that counsel for accused were instructed not to raise the plea of insanity. The question of insanity was therefore not before the Court. Our ground remains unshaken, that the state of mind of Edalji, if guilty, is primâ facie such as to demand immediate and authoritative medical investigation and report. The petition will be presented shortly to the Home Secretary. Among the additional signatures are those of Dr. Bevan Lewis, Superintendent of the West Riding Asylum, Dr. E. G. Younger, and Dr. Danford Thomas, His Majesty’s Coroner for London.

Teething Powders.

At an inquest held last week in Kensington by Mr. Luxmore Drew, the subject of teething powders was much in evidence. A child, aged five months, died after taking half a “Stedman’s” powder, with all the symptoms of irritant poison. The medical man in attendance attributed the death to the powder, and discovered, or thought he discovered, antimony in a similar powder. On the other hand, Dr. Freyberger, described as “Analyst” to the London County Council, attributed death to natural causes. He stated that he found no antimony either in the body or in the powder; but there was calomel in the powder, and a trace of mercury in the liver. In his opinion death was due to collapse from diarrhœa and vomiting, consequent upon the presence of sarcina ventriculi in the stomach. The jury returned a verdict of death from natural causes. It is doubtful whether the majority of medical practitioners of the present day would agree with Dr. Freyberger’s dictum that calomel is the proper thing to give a child while teething. Most medical men who have had much practical experience regard all “teething powders,” rightly or wrongly, with the deepest suspicion. It would be interesting to learn the general experience of coroners with regard to the number of deaths of infants who have died in convulsions immediately after the administration of a “teething” powder. Unfortunately, the report before us is too meagre to furnish the information as to whether the baby suffered from diarrhœa and sickness before any such powder was
given. The nature of the irritant in these cases is notoriously that of corrosive sublimate, due to slow chemical change in the calomel in the powder. That fact was no doubt clearly stated at the inquest by the professional analyst and County Council "expert."

The Medical Supervision of Ambulance Service.

Valuable as the services of the horse-ambulance are in providing for the transport of the sick, they are by no means always as medically perfect as they should be. Their ventilation is often imperfect, and this is especially noticeable when the patient and an attendant have to be carried some miles to a hospital. It is hardly necessary to point out the supreme importance of good springs and rubber tyres in preventing the evil effects of vibration from the road, and yet we have known both these essentials to be lacking to the detriment of the unfortunate patient, who may, perchance, be suffering from a painful recent fracture or concussion of the brain. Under such circumstances every jolt causes agony, and it is conceivable that grave surgical conditions might be dangerously affected thereby. The recent death of a widow, aged seventy, in one of these conveyances on her way to an infirmary, illustrates a most lamentable want of supervision of the ambulance arrangements, and reflects anything but favourably upon the authorities concerned. At the inquest it was stated that the vehicle contained neither rugs nor stimulants. With regard to the absence of the latter, unless such were specially ordered they would not form part of the ordinary equipment of an ambulance, but it seems incredible that some kind of covering, which, or its equivalent, would be found upon any coster's cart, was not provided. The ideal arrangement would be to ensure that every patient should be seen by a medical officer before removal to an infirmary, and that each ambulance should be provided with a lock-up cupboard containing stimulants and simple appliances for first aid, which should, preferably, be administered by the medical officer, or under his directions, by a nurse or male attendant, who should accompany every patient inside the conveyance. By such means the chances of a fatal occurrence would be greatly diminished.

The Titles of Medicinal Preparations.

The names of the different pharmaceutical compounds employed by their vendors, while vague enough from a pathological aspect, are generally sufficiently expressive to procure for them a ready sale among those individuals who are suffering from the various ailments for which such compounds profess to be a remedy or a specific. In a paper read by Mr. John Humphrey before the London Chemists' Association, (a) the principles are enunciated very clearly which have been recently laid down by the Board of Inland Revenue with regard to the liability of drugs and their preparations to duty under the Medicine Stamp Duty Acts. Such titles as "cough mixture," "corn-plaster," or "pile ointment" are now held to be dutiable, because they imply that the preparation in question is recommended for the relief of certain specified ailments. On the other hand, such titles as "hair lotion," "cooling powder," or "eye salve" are regarded as not incurring liability, as only the name of the organ or part of the human body is mentioned without reference to any particular disease. But, as part of the exemption made in favour of chemists and druggists, it will be possible to escape the duty provided that the formula of the compound be printed on the outside wrapper, or, failing that, in a work of reference which may be indicated by a number on the label. The whole question is, of course, one which primarily affects pharmacists, to whom the new regulations will make little if any difference. What the exact motives of the Board of Inland Revenue were in framing them is not quite obvious, but one thing is clear, namely, that the practice of counter-prescribing will not be checked thereby, but rather will be made easier. This is, doubtless, one of the evils of the present system of pharmacy in this country, but it is one which we are glad to believe is viewed with disfavour by chemists themselves and therefore is ultimately bound to die a natural death.

Medical Journals in Free Libraries.

The dissemination of medical knowledge broadcast among the public is a subject which may be regarded from many different standpoints. In the first place, the majority of people are better educated than they were fifty years ago, and a wider, if more superficial, knowledge of general science is slowly spreading among the reading classes. There are many people who, while fully recognising the necessity for professional aid in sickness, prefer to have some idea about the nature and symptoms of their diseases before they meet their medical adviser. Others believe, perhaps unwisely, that by reading an account beforehand of a disease from which they think they are likely to suffer they will be enabled to seek the counsel of the physician ere it is too late. In a few instances such a procedure might be beneficial, but, in the great majority of cases, it simply leads to a state of nervous anxiety and hypochondriasis. The placing of medical journals upon the reading-tables in our free libraries has been severely criticised, not by the medical profession, but by the prudish-minded and ignorant who would seek to hide the key of knowledge from the idle and curious. We should be sorry to think that the greater number of those who frequent the libraries are included among this class, for it is our experience that people read the medical papers with a sincere desire to increase their general knowledge, and, if possible, to be of some use to their friends by placing them in the right way to receive the benefits of medical science. Here and there, of course, a morbid mind may be found which devours with eager interest the most sensational details, but it would be manifestly unfair.

(a) British Pharmaceutical Journal, November 21st, 1903.
to deprive the reading public of the privilege of becoming acquainted with the newest medical discoveries and modes of treatment on this account. The truth "will out," and the science of medicine forms no exception to the general rule that "there is nothing hid that shall not be made known."

Korsakov's Disease in Women.

The affection described in 1888 by Professor Korsakov as a combination of polyneuritis, amnesia and pseudo-reminiscence, met with especially in chronic alcoholics, is gradually becoming recognised as a distinct clinical entity. Dr. John Turner, in the British Journal of Mental Science, records twelve cases occurring among women. Over-indulgence in alcohol was an exciting factor in ten of the cases, and was highly probable in the other two. In four of the patients the symptoms resembled those of delirium tremens accompanied by definite hallucinations of sight and hearing. In reviewing the general features of the disease it is stated that the confusion of mind and loss of memory are believed to be directly due to a toxic effect of alcohol upon the cell-bodies, through what is known as an "axonal reaction."

A feeling of self-satisfaction is a common symptom displayed by the patients, which, however, may alternate with periods of apathy and mental hebétude. The age at which the malady first makes its appearance is generally between thirty-one and fifty. Multiple neuritis is present in all cases in the female sex, and has been found absent only in 9 per cent. among men. The pathological anatomy is somewhat indefinite; 152 cases were collected by Soukhanoff and Boutenko, but beyond some degeneration in the peripheral nerves, no very distinct morbid change was noticed in the central nervous system. In one case Dr. Turner discovered that the Betz cells of the cerebral cortex presented the axonal reaction in addition to the usual microscopic evidences of peripheral neuritis. It is by no means uncommon to find amnesia associated with a blunting of the moral sense in female patients suffering from chronic alcoholism, though the particular combination of symptoms as described by Korsakov is less frequently observed.

Alcoholism and Tuberculosis.

Much discussion has taken place regarding the relationship of alcoholism and tuberculosis. In not far distant days it was maintained that alcohol tends to increase the resistance of tissues to invasion by infective agents, but the coming of bacteriology and the application of experimental methods to medical research have thrown some doubt on the old-fashioned custom of dosing indiscriminately fever-stricken patients and subjects threatened with tuberculosis with alcoholic medicaments. The question of alcoholic stimulation, however, stands upon an entirely different footing from that of chronic alcoholism. It has now been abundantly made clear that alcoholism greatly predisposes to tuberculous invasion. And in an alcoholic environment many factors go to the propagation of consumption. At the last meeting of the Incorporated Society of Medical Officers of Health the connection of alcoholism with phthisis received full consideration. It was shown that more than one-third of the public-house servants in London and the industrial districts die of consumption. At the public-houses, where the bars are more crowded than any workshop, infection probably takes place by spray when coughing as much as by infected dust raised from the floor. Dr. Sidney Davies, of Woolwich, has found by bacteriological analysis of the samples of sweepings from the floors of six public-houses and six large Arsenal workshops at Woolwich that the former contained tubercle bacilli in two instances, while in the latter none were discovered. It is clear, therefore, that all measures which make for the arrest of alcoholism and tend to improve the hygienic condition of public-houses are to be accorded strong support and effective procedures for combating consumption.

Myopia in Diabetes.

The effects of the perverted nutrition that accompanies diabetes mellitus are many and various, but among the less common and most interesting are those that take place in the eye. In a recent paper by Neuburger, the occurrence of myopia as the result of diabetes is well shown by two cases that have come under his notice. Both were in middle-aged women whose vision had been previously tested, and who were known to be presbyopic. In the first of the two patients, three months after the vision had been determined complaint was made of the sight being again indistinct. Instead of being able to read the smallest Snellen type with + 2 D, she could only read it with —1.5 D with the right eye and —2 D with the left. This marked change led Neuburger to test the urine, and he found it contained 3.5 per cent. of sugar. The second patient, two years after having glasses prescribed for presbyopia, presented herself with complaints of vision. On examination, she could only read 8 with —1 D with the right eye, and the same with —2.5 D. In her again, sugar was looked for and found in the urine. Marked ocular changes, like the formation of symmetrical cataract or the occurrence of retinitis or optic atrophy, will always raise a suspicion of diabetes, but it is well to bear in mind that refractive errors are the first symptom that calls for treatment in some cases, and a change from a hypermetropic to a myopic condition should always lead to a suspicion of sugar.

Sale of Poisons by Unqualified Persons.

It will be remembered that in the year 1901, a number of unqualified persons were convicted in Glasgow under the Pharmacy Act of selling scheduled poisons. These persons were all of them employed in the shops either of medical men or of chemists and druggists. Following on the successful prosecution, the General Medical Council summoned before them seven medical men whose assistants had been thus implicated, and informed them that leaving such persons in
charge of shops where poisons were for sale would, in future, be regarded by them as a gross professional offence. The Council further passed a resolution that any registered medical practitioner who should be proved to offend in this way would be judged guilty of "infamous conduct in a professional respect." During the two years which have since elapsed, no further prosecutions took place until a few weeks ago, when the Pharmaceutical Society instituted proceedings against eleven persons for offences of the nature described. A few of the defendants were unqualified assistants of medical men left in care of a pharmacy, and the charge in each case was that, not being qualified to sell scheduled poisons, they had nevertheless sold laudanum. In all the cases the charge was admitted, and fines inflicted. Apparently the medical men concerned, if it can be shown that they in any way connived at the sale, are now at the mercy of the General Medical Council. It was stated in each case, however, that the assistant had strict orders not to sell poisons, and in one case the erring assistant has been dismissed. The Pharmaceutical Society, it seems, with considerable forbearance, let two entire years pass without action, to allow medical employers and others to accommodate themselves to the ruling of the General Medical Council. That so many have failed to do so does not speak well of the care exerted by these gentlemen.

Physiology Extraordinary.

In a certain class of books which were very fashionable in these countries about nine or ten years ago, the general teaching seemed to be that there was no study of so great importance to the guidance of life as physiology. It was taught that all ills might be avoided by such knowledge, and all happiness attained thereby. We were told that the young woman who made an unhappy marriage had been sacrificed either by her own or her parents' ignorance of the laws of physiology. It is true that most people who talked and wrote glibly on the subject had the haziest notion of the meaning of the term, but nevertheless it was impressed on the public that they must study physiology. In America this conviction has taken root, sprung up, and borne fruit—grapes or thistle-tops? In the elementary schools the children must study physiology, and the fruit is sometimes very abortive, if we are to judge from some items of knowledge we have seen quoted in a contemporary. We learn from one pupil in answer to a question that "physiology is to study about your bones, stumnick and vertebray." Another states that "gastric juice keeps the bones from creaking," and a third that "the stomach is a pear-shaped bone in the body." Another student of development is convinced that "the growth of a tooth begins in the back of the mouth and extends to the stomach." But the most original of all the information gained is that regarding the digestive juices of the stomach—"in the stomach starch is changed to cane sugar and cane sugar to sugar cane." We would rather have run chance with the starch, as the possibilities of the suggested change are too alarming. Seriously, we cannot see that anything but harm results from cramming the minds of children with information they cannot at all assimilate.

A Diploma in Tropical Medicine.

In these days when degrees, diplomas, and "letters after one's name" are all the rage, and when the methods of commerce have permeated the vitals of our educational systems, there is no need for surprise that a diploma in tropical medicine and hygiene is well on the way to be established. The Special Board for Medicine at Cambridge has just reported to the Senate of the University its views upon the proposal to grant such a diploma. It dwells mainly on the necessity of encouraging the study of the diseases of warm climates by medical men before going to practise abroad. Mr. Chamberlain, when approached on the subject, expressed full sympathy with the proposal, and Mr. Brodrick gave the equivocal, nerveless kind of reply to a communication on the subject that might have been expected of the late head of the War Office. It is proposed that the diploma follow much the same lines as those laid down for the D.P.H., so that it would be open to all registered medical practitioners of one year's standing. Courses of bacteriology and parasitology, of clinical instruction in tropical diseases and of tropical hygiene are prescribed, and credit will be given for original research work in these subjects. From the favourable manner in which the report of the Special Board was received, the necessary powers will probably be readily granted, and then every other University and medical corporation, not wishing to be left out in the cold, will follow suit. It is bewildering to speculate whether this degree and diploma-granting movement will lead. Shall we find ourselves battling in the next decade or two for special qualifications in ophthalmology, laryngology, gynaecology, and otoLOGY? Fortunately the alphabet possesses considerable flexibility, and can serve for an incalculable number of permutations and combinations, but its powers will be considerably taxed to describe the medical man of the next generation. In the meantime, it is well to remember that Cambridge was the first body to institute a D.P.H. examination, and it is a welcome sign of vitality and adaptation to modern requirements that it seeks to follow its own precedent by inaugurating another new departure—a D.T.M.

"Shambles of Science."

It is not always a disadvantage to see ourselves as others see us, and the book with this alluring and alliterative title, to which reference was made so frequently in the Bayliss v. Coleridge libel action, is not without its interest. It was penned by two Swedish ladies who came to this country on behalf of the Scandinavian Anti-Vivisection Society, and who entered as students of physiology at the London School of Medicine for Women, and subsequently at University College, London.
They protest, in the preface, that their object in so doing was not merely to obtain "copy" to support their movement, but also to take a scientific degree. Their reason for abandoning this course is stated to be that physiology being inseparable from experiments on animals, nobody objecting to them could have any chance of a degree. The ladies, however, do not seem to have abandoned their intention till they had been through a pretty full course of physiology, and one is tempted to think that they found it easier to write flamboyant nonsense than to graduate at the London University. In fact, materialism in any form seems to be a bug-bear to them; "vitalism" they contend for in physiology, and, one would suppose, "vividity" in literature. Certainly they are not dull; every page is alive with lurid detail, and the only monotony in the book is the uniform failure of the demonstrators to bring off any experiment they attempt. But the good ladies prove too much; it is no use inveighing against the brutality of men who are under the influence of "the Cartesian doctrine that animals possess neither feeling nor consciousness," for if they hold such views surely anaesthetics would be obviously superfluous. Descartes is rather a dangerous authority to invoke; if one were to adopt his principle of Cogito, ergo sum, one would be forced to the conclusion that these ladies did not exist, and yet no one reading the "Shambles of Science" could deny that they were very much animated by "vitalism." One phrase they seem much pleased with—"Vivisection is bankrupt"; what this signifies is not quite clear, but perhaps the £2,000 which Dr. Bayliss received in damages, and which he is going to apply to physiological research, may help to keep it a little longer out of liquidation. The Lord Chief Justice aptly described the work as "a hysterical book," but it is worth reading as an example of what blind prejudice, fed on heated imagination, can do, and it contains wonderfully few grammatical errors for a book written by foreigners.

**Exercise of the Abdominal Muscles.**

Every surgeon knows that there is a certain lax condition of the muscles of the abdomen which is very markedly a predisposing cause to the production of hernia. After a laparotomy for any purpose there is, in abdomens of loose, flabby, or pendulous walls, a great tendency to ventral hernia, and to its repeated reproduction in spite of operative treatment. It is surprising how little has been done by any treatment of the muscles to remedy this serious condition. Yet, as Mr. Dowden, of Edinburgh, points out, (a) if proper care be taken, the tone and strength of these muscles can be restored to an almost incredible degree. Repeated and regular exercise of the muscles is all that is needed. The abdomen must be pulled in as flat as possible and this position maintained as long as practicable; this should be done several times a day. Other exercises, such as stooping with the knees stiff, and, if thought necessary, massage may be added. Even in a few weeks an astonishing change is noticed in the condition of the muscles. In cases complicated with obesity, an equally good result is obtained, and in one case related by Mr. Dowden, the only drawback to the success of the treatment was that the patient grumbled at the ill-fitting of his waist-band, owing to the decrease of his girth.

**PERSONAL.**

The annual dinner of the Irish Graduates held last week in London proved a most successful affair under the able presidency of Dr. Philip Abraham.

Dr. George Carpenter is the editor of the newly-established *Journal of Diseases of Children*, the first number of which is announced for January, 1904.

Sir Thomas Myles formally opened the new theatre of the Carnarvonshire Infirmary on the 23rd ultimo in the presence of a large and distinguished company.

The annual dinner of the British Gynaecological Society, which was to have been held on November 27th, was at the last moment unavoidably postponed.

It will interest readers to learn that the damages awarded to Professor Bayliss in the late libel action brought by him against Mr. Coleridge will be devoted, in some form not as yet decided, to the furtherance of physiological research at University College.

An interesting lecture was delivered on the 27th ult. at Westminster Hospital, London, by Professor Ralph Stockman, as Guthrie Lecturer for the year. Dr. Stockman is peculiarly fitted to deal with the subject of the lecture, namely, "Arrow and Ordeal Poisons."

**Surgeon-General Sir William Taylor, Director-General Army Medical Department, will present the prizes and certificates to the members of the Volunteer Ambulance School of Instruction on December 14th at 130 Bunhill Row, the headquarters of the London Rifle Brigade.**

The inaugural sessional address of the Pharmaceutical Society of Great Britain was delivered in Edinburgh last week by J. Taylor Grant, M.D., B.Sc., Lecturer on Bacteriology at the Edinburgh Royal College. The subject chosen was "Bacterial Therapeutics."

Professor Bayliss desires to thank the numerous correspondents, many of them strangers to him personally, who have written to congratulate him upon the result of the recent trial. He speaks of letters coming from gentlemen who are not physiologists, and not even medical men, as specially gratifying.

Mr. R. A. D. Daniel, M.D., Durh., who until recently had an extensive practice in the Hammersmith and Chiswick districts of London, was, on November 13rd, presented with a testimonial from patients in the shape of a silver tea and coffee service and hot-water jug together with a cheque.

The autumnal dinner of the Durham University Medical Graduates' Association will take place on Thursday, December 3rd, at the Café Monico, London, at 7.30 p.m., under the presidency of Dr. Frederick Spicer. Further particulars may be obtained from Dr. T. Outterson Wood, 40 Margaret Street, W.
There were several penal cases for consideration. Various tables embodying the results of the recent examinations for commissions in the Army, Navy, and Indian Medical Services were received.

Mr. George Brown said it would be a good thing if a copy of the tables could be sent to every licensing body.

Sir Patrick Heron Watson moved, and Dr. MacVail seconded, that the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy, to the Director-General of the Medical Department of His Majesty’s Army, and to the Under-Secretary of State for India, respectively, for these Returns, with the request that the same might continue to be furnished to the Council.

Dr. Payne proposed, and Dr. Macalister seconded, that Sir John Battie Tuke and Dr. Macalister be chosen to act as Representatives of the Council to meet the Consultative Committee at its forthcoming Conference on December 4th.

The Council adjourned at 4 p.m., to enable certain Committees to complete their reports.

SECOND DAY.—Wednesday, November 25th, 1903. PENAL CASE.

The whole sitting was occupied by the resumed consideration, in camera, of the case, adjourned from May 28th, 1903, of a practitioner in a country town, an M.D. and M.S., R.U.I., who had been ordered to appear before the Council on a charge of indecent assault upon certain female patients whom he had attended professionally.

Upheld by the re-admission of the case, the President informed the defendant that the Council had deliberated upon his case, and had arrived at the conclusion that the facts which were alleged against him had not been proved to its satisfaction.

The Council then adjourned.

THIRD DAY.—Thursday, November 26th, 1903.

A Report was received from the Executive Committee on certain dental business transacted since the last Session of the Council. The names of thirteen individuals were restored to the Dentists’ Register, from which they had been removed in conformity with the provisions of Section 12 of the Dentists Act, 1878.

An application from Mr. Spence, an unregistered dentist, was considered, but the Executive Committee did not recommend the Council to accede to his application.

The Council next proceeded to the reconsideration of the application of Mr. J. E. Bush for registration as a dentist under Section 37 of the Dentists Act. Mr. Bush was in practice at Melksham, in Wiltshire, both as a dentist and also as a chemist, and having taken the minor qualification of the Pharmaceutical Society in 1889. His former application was three weeks after the date—August 1st, 1879—before which those persons who were already in practice at the time of the passing of the Act and were desirous of becoming registered under clause 7 should apply. He was, moreover, nearly becoming registered in 1896. He had produced excellent testimonials as to his social and professional esteem with which he was regarded, and he was willing to relinquish his business as a chemist, and also promised to give up his former methods of advertisement, for which he had once been prosecuted by the British Dental Association.

Mr. Tomes said that he was sorry to take the position that he did, in view of the esteem in which this gentleman was regarded, but he could not help saying that the Council should not accede to the application of Mr. Bush. This was seconded by Dr. Macalister and carried.

The next case was that of Allan Douglas Cameron, L.R.C.P.E., L.R.C.S.E., L.F.P.S.G., of Durban, Natal, who was charged with committing adultery with a married woman whom he had been attending pro-
fessionally, namely, Mrs. Tothill, Mr. Louis E. Fawcett appeared for the defendant, who was in India, and Mr. John Tothill, brother of the complainant, gave evidence as to the intimacy between Dr. Cameron and his sister-in-law.

The Council then deliberated in camera, and on the re-admission of strangers the President informed Mr. Fawcett that the Council had adjudged Dr. Cameron to be guilty of infamous conduct in a professional respect, and the Registrar was therefore directed to erase his name from the Medical Register.

The next case was that of Robert Fawcett Granger, L.R.C.P.S.E., L.F.P.S.G., of Whibly, who was summoned to appear in consequence of his conviction at Plymouth of a misdemeanour in neglecting his three children in a manner likely to cause them unnecessary suffering. The prosecution was undertaken, in the first instance, by the Society for Prevention of Cruelty to Children. The case was regarded by the magistrates as one of great seriousness, and both the mother and father were sentenced to two months' imprisonment.

Dr. Granger read his defence, in which he stated that there was a great deal of local prejudice against him and his family, that his circumstances were much reduced, and that the case had been greatly exaggerated. He insisted that the family troubles had led him to adopt drinking habits, but that he had been more abstemious lately.

Mr. G. F. Watts, an officer of the Society for the Prevention of Cruelty to Children, stated that he accompanied the warrant officer at the inspection of the defendant's house, which presented the appearance of poverty. He thought that the practice of the defendant might improve with attention.

The Council then deliberated in camera, and on strangers being re-admitted, the President informed Dr. Granger that the Council had carefully considered his case and were willing to give him an opportunity of redeeming himself. He would, therefore, be given six months' probation, at the end of which time he would have to produce certificates of having amended his ways at the next meeting of the Council.

The next case was that of David Barnett Bradlaw, L.R.C.P.A.S.I., of Dublin, who appeared in order to satisfy the Council of his conduct since its last meeting, when he was charged with having carried on a dental practice in the name of and of using his brother, the facts having been proved to the satisfaction of the Council.

Mr. Bradlaw read a statement to the effect that his brother had ceased to practise, and that his own practice had been conducted in accordance with the best traditions of the profession.

Mr. R. W. Turner having given evidence on behalf of the British Dental Association as to the correctness of the defendant's statements, the Council then retired in camera.

When strangers were re-admitted, Mr. Bradlaw was informed by the President that the Council had considered the facts alleged against him, and that it did not judge him guilty of infamous conduct in a professional respect.

The Council next proceeded to the consideration of the case of Louis Edward Delmege, L.R.C.S.I., L.R.C.P.E., of Burton, Westmorland, who was summoned to appear before the Council in consequence of his conviction of having deserted his wife.

Mr. F. J. Shaw, on behalf of the defendant, stated that domestic relations had become so strained that Mrs. Delmege had left her husband's house, not, as was alleged, that the doctor had deserted her.

As a matter of fact, the doctors were in progress towards a reconciliation, when he was arrested with a Scotch warrant by two detectives in London, and at once taken to Glasgow without appearing before any magistrate in London.

The question of the legality of such a method of procedure having been raised by several members, the Council then deliberated in camera.

On strangers being re-admitted, the President informed Dr. Delmege that after hearing his case they had decided not to erase his name from the Register.

The Council adjourned at 5 p.m., after deliberating in camera upon an item of business.

FOURTH DAY.—Friday, November 27th, 1921.

Reports were received from the Examination Committee on the inspection of the primary examinations of the Scottish and Irish Conjoint Boards, and also on the whole series of inspections of primary examinations.

Mr. Bryant, after reading the report bearing upon the examinations of the Scottish Board, moved, and Mr. Young seconded, that it should be accepted. It was therefore entered upon the Minutes.

In the discussion which followed, Dr. Windle remarked that the system of marking was very complicated.

Sir John Moore could not agree with the view expressed in the Report that the paper in biology was the least important part of the examination, and he thought that the examiners appeared to contradict themselves on this point.

The President said that this was chiefly a matter of opinion.

Sir Victor Horsley moved, and Mr. Jackson seconded, that this report be adopted, but that in the opinion of the Council the examination in practical chemistry was insufficient. This was carried.

The report on the Irish examinations was next read. Dr. Norman Moore thought that for the work "sufficient," "satisfactory" should be substituted, as the former was only a technical term.

Dr. Macalister pointed out that the whole report was being adopted, including the opinion that the examination was sufficient.

The report upon the whole series of inspections of primary examinations was next received. An amendment moved by Sir Victor Horsley, and seconded by Mr. Tomes, that it should be discussed forthwith was lost by 7 votes.

Mr. Bryant then moved, and Sir Charles Ball seconded, that a joint committee be formed consisting of members from both the Examination and the Education Committees to consider the questions raised generally in this report, and that they should report thereon at the next meeting of the Council. This was carried, and Mr. Bryant, Dr. Vail, Sir Charles Ball, and Mr. Young were chosen as representatives of the Examination Committee, and Dr. Windle, Dr. Norman Moore, and Sir John Tuke were appointed representatives of the Education Committee, Sir William Turner as President of the newly constituted Joint Committee.

The Council next proceeded to the consideration of the case of Henry Jacob Bradlaw, a registered dentist, of 4, Harrington Street, Dublin, who appeared to answer certain charges of advertising.

Mr. R. W. Turner represented the British Dental Association. Evidence having been given that the defendant had associated himself with an advertising firm of dentists, and that he was a shareholder, and ipso facto a director, of the company, strangers then withdrew and on their re-admission, the President informed Mr. Bradlaw that the Council considered his conduct to be infamous in a professional respect and that the Registrar was directed to erase his name from the Register.

The next case was that of William Herbert Ray, a registered dentist of Margate, who attended in consequence of his conviction of a certain offence against a female patient, for which he was sentenced to thirty-one years in practice, and a petition, signed by
many industrial people was presented to the Home Secretary on his behalf, but without avail.

At the trial, the defendant had again reiterated his complete innocence of the charge, and the Council entered into the discussion of the case in camera. On the re-admission of strangers, the President informed Mr. Ray that the Council had given much consideration to his case, and that they intended to take no further steps in the matter. He would, therefore, continue to remain on the Register.

The next case for consideration was that of JAMES GRANT, a registered dentist, of London, with regard to whom the Dental Committee had reported that he had identified himself with an advertising firm which was managed by an unqualified and unregistered man named John Panhan.

The British Dental Association was again represented by Mr. R. W. Turner, who stated that that Association regarded this case as a serious one in that the defendant deliberately attempted to defeat the ends of justice. He hoped that the Council would therefore mete out to him the full penalty.

Mr. Grant was not present to offer further explanations.

Strangers then withdrew, and on their re-admission the President announced that the Council had directed the Registrar to erase the name of James Grant from the Register.

The Council then went in camera and on strangers being re-admitted, the President announced that the Council had directed that the name of Mr. James Jerome Mackay, of Stockwell, should be restored to the Register.

The Council then adjourned.

Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENTS.]

SCOTLAND.

DUNDEE ASYLUM.—The unsatisfactory state of matters in this asylum, to which reference was recently made in this column, culminated in the resignation of the medical superintendent, which was handed to the Asylum Board on the 24th ult. The district Board had requested the General Board of Lunacy to make an inquiry into the conditions of the patients in the asylum on September 24th. The report of the inquiry held in response to this request, which was based on a full investigation of all the circumstances, was read at the district meeting on the 19th, and the meeting of that date was adjourned till the 24th in order that the medical superintendent’s explanation might be heard. The following is a summary of the General Lunacy Board’s report:—(1) On or about September 15th, the patient in question received injuries to the chest sufficient to account for death. The cause of these injuries was not definitely ascertained, but there was some evidence that they were not due to a fall from bed, but to pressure or blows applied to the chest by person or persons unknown. (2) Dr. Rorie’s report to the General Board, bearing to be founded on the post-mortem report, was incorrect, in so far as it described the injuries as “semi-fracture (tending inwards)” of four ribs, whereas the post-mortem register and the evidence of Drs. Mack and Shepherd show that eight ribs were fractured, and the fractured ends were movable. (3) The Board think that the superintendent did not, and does not even now, realise the gravity of the matter, for (a) he learned that a patient had received an injury to the chest, and also got what is called in his diary a “curious story” about a patient who had been tied down and failed to connect the two circumstances; he had made improper inquiry he would have discovered, as the Board did, that another patient had been tied down a fortnight previously, and thus the case also had happened in the case of the patient who died. (b) But for telegraphic instructions of the Board, it is clear that Dr. Rorie would not have reported the case to the Procurator Fiscal. (c) His letter to the Fiscal was so unfortunately expressed as to convey pretty clearly the writer’s, no doubt honest, opinion that there was no ground for an inquiry. It was likely to put the Fiscal off his guard. Dr. Rorie stated that the Fiscal was contented to examine himself and three attendants, and did not seek to examine the attendants in charge of the patient by day, the assistant medical officers, or the post-mortem register. All the information was thus limited the Board fear it must be explained by the terms of Dr. Rorie’s letter to the Fiscal, but be that as it may, the Board think that Dr. Rorie ought to have given the Fiscal information as to what he heard about tying down, to have shown his post-mortem register, to have suggested the examination of all the attendants, as well as of the assistant medical officers, who must have had greater personal knowledge of the circumstances than the superintendent, seeing that the latter had been away on holiday prior to September 16th. (4) The Board find that male attendants, on joining the asylum, are placed in the sick room, where special and acute cases are treated; in consequence, patients requiring most care get least experienced attendants. The system, which is defended on the ground that it affords training in nursing to new attendants, is regarded by the Board as indefensible and injurious to the insane. In this particular case the length of service of the three attendants in charge of the sick wards was four weeks, four weeks, and three weeks; that of the other attendants four months. One of these men was dismissed from the Asylum’s service on September 8th, and another left just before the Fiscal’s inquiry. At the adjourned meeting which considered the above report, Dr. Rorie read a statement which he had prepared. The General Board of Lunacy wrote to him, intimating that they had considered a report (that quoted above), and offering to hear any explanation he had to offer on the subject. He accordingly met the Board on the 10th. In judging of the completeness of the investigation made, it had to be noted that the injuries occurred in a person seventy-nine years of age, who on admission had bruises on various parts of his body and chest, and who was known to have fallen repeatedly before being taken to the sick-room, and whose demented condition prevented any information being got from himself. On September 16th fresh bruises were found, and a fracture of the right rib was noted. It was known that he had fallen several times out of bed. It was to be noted that the injuries were sustained during his own absence and that of the head attendant. More serious than the above injury was the post-mortem observation that the patient had been diagnosed, but this was not unusual, and did not surprise him much. Since he had satisfied himself between the date of his return and the patient’s death that the injuries were probably due to falls, he did not think it necessary to make so rigid an investigation of all the attendants who had been in contact with the patient as if the post-mortem had shown unexpected injuries. As to the view of the Board that his letter describing the cause of death was inaccurate, Dr. Rorie pointed out that it was merely a record of the principal injuries noted by himself, and not a complete report. It did not claim to be founded on the post-mortem register, which as a matter of fact had not been extended at the time his letter was written. In reference to the sick-room arrangements, the three newly-joined attendants were under the charge of a very intelligent chief, whom Dr. Rorie considered suitable for the position that he had advanced him in order to retain his services; he was unfortunately ill at the time when the injuries took place. Such were the principal facts which Dr. Rorie had brought under the notice of the General Board. The only point of which he had had to modify his opinion was as to the patient having been tied down and as to his having failed to connect this and the injuries received. When first heard the story he regarded it as incredible, on account of the precautions in force, that such should have happened without his knowledge. As, however, the Board had informed him, in reply to a direct ques-
tion, that they had evidence of this, he had reinvesti-
gated the matter, and found the Board's statement
contradicted. After all, it was an open question
whether the suspected use of restraint had any con-
nection with the injuries. As to his dealings with the
Fiscal, he had not thought the case one which ought
to be committed. He had been very much of the
belief, as he still did, that the injuries were due to falls out of bed. The nature and
extent of the Fiscal's examination were left to his own
judgment, and he might say that the Fiscal informed him that
he had examined as many persons as he con-
sidered necessary. He concluded as follows: "—While
I thus feel that I have exonerated myself from any trace
of neglect or blame in this matter, I desire, neverthe-
less, to say that, as I have apparently not had
considerable time to pass over the case since it took over the
management of the Asylum, I consider it will now
be best to retire from its service, as I now do."

The resignation was accepted by the Board, and a
committee appointed to take the necessary steps to fill
up the vacancy.

Glasgow Southern Medical Society.—At
a meeting of this society held on the evening of
the 26th inst., ex-Councillor John Carswell, F.F.P.S.G.,
delivered an address on "Alcohol and Preventive
Medicine." From his official position on the Parish
Council, and as the late Convener of the Gregorie Home
for Female Inebriates, he was in a position to speak
with authority on a subject with which he was
familiar, and to every member of the medical profession. Mr.
Carswell, by means of diagrams, pointed to the high
dearth-rate prevailing in some of the poorest districts
of the city, compared with others where there was less
overcrowding, and how the sanitary measures adopted
by the municipality had very materially lowered the
dearth-rate. He referred to the ravages of strong
drink, but was not disposed to agree with those
who believed that heredity was playing an important
and responsible part in creating and continuing the drink
vogue in the children of drunken parents; neither did
he consider that alcohol was responsible to the extent
it was generally credited, through inheritance, in many
cases of insanity. An animated and instructive dis-
cussion followed in which Dr. Chalmers, Medical Officer
of Health, Carstairs Douglas, Alex. Miller, D. Mac-
gilvray, and others took part. Dr. Macgilvray
believed that in the case of a pregnant woman much
addicted to drink the child materially suffered, and
did not arrive at that maturity attainable where the
mother was not given to drink. The President of the
Society, Thos. Richmond, thought Mr. Carswell had taken a very
optimistic view of the hereditary aspect of the question,
and, with reference to insanity, was of opinion that
Mr. Carswell's pronouncement did not quite accord
with the opinion expressed by the superintendents of
our asylums, who considered alcohol as being responsible
for a large percentage—some say about 30—of the
cases of insanity in our asylums. A hearty vote of
thanks was awarded Mr. Carswell for his interesting
address.

Glasgow Samaritan Hospital Bazaar.—We
have referred to this hospital before, and to its
inception only five years ago in a very modest
way. It is situated on the south side of the river Clyde, and
in its present position—not the original—has about
thirty beds for women. The bazaar which has just
began has been a magnificent success, the enormous
sum of between £15,000 and £20,000 having been
realised. This will allow of a very large extension of
the hospital, to something like fifty or more additional
beds. The sum aimed at by those in charge of the
bazaar is £5,000. The splendid results achieved
are in a very large measure due to the great, nay, the
absorbing, interest which the ladies took in the matter.
The bazaar was opened by the Princess Henry of
Battenburg, and the admission charge on that day was
five shillings. The extension of the hospital is urgently
required, as there are constantly a considerable number
of suffering women waiting for admission.

pondents.]

THE AFTER-TREATMENT OF INTRA-NASAL
OPERATIONS.

To the Editor of The Medical Press and Circular.

Sir,—In your otherwise excellent issue of last week, begun
of my remarks in the discussion on this subject at the
meeting of the Laryngological Society of London, there
is one omission of such importance that I feel justified in
asking you to give me space for its introduction.

Before applying the galvanic current to the nose, I
make it an irrevocable practice to follow the
rule laid down many years ago by an American rhino-
ologist whose name for the moment I cannot recall, namely, to dry most thoroughly by means of absorbent
cotton wool the portion to be cauterised and the portion
lying opposite it. In this way the danger of bringing
about a scald of the surface opposite to that on which
we operate is avoided. If fluid be allowed to lie
between the two opposed surfaces, this must obviously
tend to be raised to the boiling point and to lead to the
traumatic lesion referred to. The chances of the two
opposed raw surfaces becoming adherent to each other
would, therefore, be very great, and the importance of
avoiding this by the careful drying referred to must be
obvious.

I am, Sir, yours truly,

Dundas Grant.

18, Cavendish Square, W., Nov. 25th, 1903.

A QUESTION OF MORALS.

To the Editor of The Medical Press and Circular.

Sir,—I should much like to know what view most of
the readers of your journal would take of the following
case—

An elderly lady of some reputation, as the intimate
friend of some of the best-known literary men in
London, survived most of her friends and relatives and
lived into a state of mental and physical sensibility.
She had a fair income from a life interest, and she had

BELFAST.

Ulster Hospital for Children and Women.—
This hospital, which has for many years been doing a

THE MEDICAL PRESS.

CORRESPONDENCE.

some small property, which it was her wish to leave to
a favourite maid who became her nurse and constant
companion, and to whom she had taught the letters of
one of our most distinguished authors, and they were
of singular value. The medical practitioner who
attended this lady for many years was her intimate
friend, and knew what her wish was in regard to
this her property. Her one great wish was that the letters
should be burnt when she died, and that no one should
see them. She could not bear to destroy them herself,
but in her illness, in which she had the greatest
solicitude, would do so. A will was made when the lady
was perfectly capable, but nothing was purposely said
in it about those letters. Thus matters stood for about
three years after the will, and then everything was
changed, for the nurse died first, and then the lady's
mind and memory rapidly broke down. She became
quite incapable of understanding anything,
and might have signed any document put before her.
The medical practitioner who had known her so long
was obliged to give up his care of her and another
succeeded him. About two years later the lady died,
and a will was produced leaving all she had to some
constable who occupied the place of the companion. The
letters were sold for several hundred pounds, and no
one seemed to take any interest in all that had happened.
It is true, it was not of any practical importance to
the will, to attend this lady after the
death of the companion, report or in any way inter-
fere with what was done; and as there is no legal
obligation imposed upon practitioners in such cases,
the question is one of moral and professional importance
upon which it would be well that the profession should
agree.

I am, Sir, yours truly,

Quereus.

West Kensington.

[This concrete case, of which we have been furnished
with full details, raises a question of the utmost im-
portance from the point of view of professional
morality.—Ed.]

FORENSIC MEDICINE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sr.—Some years ago I was lecturer on forensic
medicine at the Westminster Hospital. I well remem-
bered, when I undertook this work, the dull and un-
interesting course I had gone through when a student
at St. George's. Forensic medicine was a subject that
always seemed to me disagreeable when preparing the
Cambridge M.B. or any other examination.

It was such a wide subject, and what books to read or kind
of questions to prepare to answer seemed impossible to
decide. The lecturers themselves appeared to take no
interest in it, and altogether it appeared to me that it
was a mistake to make forensic medicine a special subject in
the medical curriculum. This led
me to making a change at the Westminster Hospital.
The only work I felt able to do properly was the post-
mortem examination in cases of doubtful causes of
death, in injuries, and wounds, and in that particular
line of inquiry which belongs to morbid anatomy and
pathology in their widest sense. As I was pathologist
at the hospital and had the direction of the post-mortem
work I saw the way to turn to account the material
supplied by the post-mortem room in the lectures on
forensic medicine. When the question of poisons came
up and the testing of the contents of the stomach, and
this quite different kind of inquiry had to be considered,
I went to my friend, the lecturer on chemistry, and
arranged with him to give some lectures on this subject.
And when there was another of these cases I did not
see clearly how to deal with, and that was insanity. As
these three divisions or classes of cases formed the chief
part of every course of lectures on forensic medicine,
I thought it well and proper that the lecturer should
qualify to deal with them. It ended in my keeping
to the post-mortem and pathological work, in my friend
the lecturer on chemistry taking the poisons, and in Dr.
Sparrow giving six lectures on insanity. We
managed pretty well in this way to interest the students
and relieve the subject of forensic medicine of some of
its dulness and unpractical value. Gradually thing
have changed, and now the importance of special
knowledge in morbid anatomy, chemistry, and insanity
is being recognised in cases of legal interest. It seems
as if it would be better to do away entirely with
forensic medicine as a special subject in the curriculum
of medical residence, and let each of those divisions of it which
are so well recognised be treated of by the lecturers to
whom they can be properly entrusted.

I am, Sir, yours truly,

Robert Lee.

THE GORDON BLACKMAILING CASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sr.—In acknowledging the receipt of cheque for
£51 7s. 4d., so kindly contributed by medical brethren
inwards defraying the costs incurred by me in what
is now known as a notorious blackmailing case, I
have to express my deep obligation to the subscribers
for their thoughtful act of generosity, which will be
always appreciated and remembered by me.

To the presidents of the two colleges I have also to
tender my sincere thanks for the part they took in
the movement.

To Dr. Horne, as honorary treasurer, and to Dr.
Wayland as honorary secretary, I owe indeed a great
debt of gratitude, and there are others with whose names it
might be invidious to mention, to whom I will for ever feel
indebted, on account of their practical sympathy. I
have also, sir, to acknowledge your kindness and
courtesy in opening the columns of THE MEDICAL
PRESS AND CIRCULAR to the inauguration of the fund
and to the strenuous manner in which its support
was advocated. I should not omit mention of the lay
Press for the spontaneous way in which it assisted our
professional organ in this matter.

May I add a word of acknowledgment to the many
medical friends who wrote me such kindly letters of
sympathy in a trying ordeal in which not only my
own character, but the honour of the profession, was at
stake.

I remain, Sir, yours truly,

A. Alexander Gordon.

18, Rathmines Road, Dublin, Oct. 26th, 1903.

MEDICAL MAYORS.

The list of medical men elected to the mayoral
chairs in various parts of the kingdom is always of
interest to their professional brethren. The names,
to be as far as ascertainable, of those who have not
had municipal elections are appended, together with
portraits of the greater number of them.

Hampsted.—Edward Collingridge Andrews, M.D.,
Fetab, M.R.C.S., son of Dr. J. Andrews, has been
elected. Took the M.B. degree of Cambridge in
1886, and the M.D. in 1892. He became member of
Borough Council in 1900 and was made chairman of
health committee and later of housing committee.

Bridport.—S. J. Alden, M.D., M.B., L.R.C.P.,
Lond., M.R.C.S., Eng., educated at the University of
Durham and St. Thomas's. In 1888 he took the degrees
of M.B., B.S., and in 1890 the degree of M.D. He
has been a member of the Bridport Town Council
for six years, during which time he has filled the office
of chairman of the sanitary committee and other public
functions.

Wareham (Dorset).—F. O. Bell, who for some years
has occupied a prominent position in local politics,
graduated as M.B., C.M., in 1893, in the University of
Edinburgh.

Fulham.—William Banks, M.B., M.C., L.R.C.S.,
Eng. He became M.R.C.S., Eng., in 1879, and M.B. of
London University 1886. He entered the council in 1892
and was elected alderman in 1898, Mayor in 1902,
and again in the present year.

Cambridge.—J. H. C. Dalton, M.D., D.P.H.Cantab.,
was twelfth wrangler in 1884. In 1889 he became a
Licentiate of the Society of Apothecaries. In 1893
he took the M.D. degree of Cambridge University.
He eventually settled at Cambridge, where he has filled
a number of official positions.
Dorchester.—E. W. Kert, M.D., M.Ch.Dub., was born in 1849 near Dublin. He was educated in Dublin, and graduated B.A., M.B., and M.Che. in 1872 and M.D. in 1889 and became L.M.K. and Q.C.P.I. in 1872. Before going to Dorset in 1884 he practised in Ireland. He has been a member of various committees.

Denbigh.—David Lloyd, M.B., M.S.Glasg. (1891), J.P., was educated in Glasgow and London.

Hounslow.—J. C. Macaulay, M.R.C.S.,Eng., L.S.A., has held the civic chair on no less than five previous occasions—namely, in 1884, 1887, 1894, 1901, and 1902. He took the diploma of the London College of Surgeons in 1885, and of the Apothecaries in 1886.

Hoxton.—R. B. Searle, L.R.C.P.Lond., M.R.C.S.Eng. He became M.R.C.S.Eng. so long ago as 1853, L.S.A. in the same year, and L.R.C.P. in 1865, and has been in practice for nearly half a century.

Obituary.

DR. GEORGE EUGENE YARROW.

We regret to announce the death at his residence, Colebrooke Row, Islington, of Dr. George Eugene Yarrow, until recently deputy-coroner for North-east Middlesex. At the time of his death, and for many years previously, the deceased was chief medical officer at the City Road Lying-in Hospital, and divisional surgeon to St. Luke's section of the G division of police. He was also a member of the Hospital Board of Guardians, and prior to that was medical superintendent of the City Road workhouse. The death was attributed to blood poisoning. Dr. Yarrow became L.S.A.Lond. in 1861, L.R.C.P.Lond., 1871, M.D. of the University of Hadelberg in 1867, and D.P.H. in 1889. He was a prominent citizen of Islington, where he carried on an extensive practice.

DR. JEREMIAH KEIGHLEY.

The somewhat sudden death has been announced of Dr. Jeremiah Keighley, in his sixty-ninth year, at Stonefall Hall, near Harrogate. Dr. Keighley formerly practised at Kirkstall, but resided some years ago at Stonefall Hall. Of a genial disposition, he was well known and widely respected in Harrogate and district. As recently as Thursday last he followed the hounds, and was apparently in accustomed good health. A widow and two sons survive him. He became a member of the English College of Surgeons in the year 1863.

DR. THOMAS HIGHTON.

The death of Thomas Highton, a well-known medical practitioner of Derby, under painfully sudden circumstances, is reported. He had been unwell for several days, but went on his work. When thus engaged he was taken ill on Friday last, and was assisted into a neighbouring shop. Mrs. Highton was communicated with, and the unfortunate gentleman was conveyed home, where he died. He was fifty-four years of age, was a native of Leicestershire, and when he first came to Derby was house surgeon at the infirmary. He afterwards commenced practice on his own account, and his last begins him many friends there. The late Mr. Thomas Stuveyngton. He took the M.R.C.S.Eng. in 1873, and the L.S.A.Lond. in 1875.

FLEET-SURGEON GILBERT KIRKER, R.N.

We regret to announce the death of Fleet-Surgeon Gilbert Kirker, K.N., appointed to Haslar Hospital in July, 1914, and died at that institution last week from acute nephritis. The malady from which he suffered was probably aggravated by blood-poisoning contracted while performing a recent operation. Dr. Kirker, who took his M.D. degree at the Royal University of Ireland, won the Parkes Memorial bronze medal in 1880 and Sir Gilbert Blane's gold medal in 1892. He then served the navy in 1879, became a lieutenant in 1881 and a fleet-surgeon in 1889. During the Egyptian War in 1882 he served as surgeon of the 'Iris.' Rear-Admiral Dundford, when distributing the prizes at Haslar Hospital on September 30th last, paid a warm tribute to the capacity and teaching ability of Fleet-Surgeon Kirker.

Dublin Death Rate.

The deaths registered during the week ending Saturday November 21st, 1903, in the Dublin registration area represent an annual rate of mortality of 25.0 in every 1,000 of the population. Tuberculous disease caused 33 deaths, diseases of the nervous system caused 15 deaths, diseases of the circulatory system caused 27 deaths, and diseases of the respiratory system caused 50 deaths; 49 infants died during the week, of whom 31 were infants under one year old. In the city the death-rate was, in the Summer Hill district, 29.3 per 1,000; in the Lissburn Street district, 27.7 per 1,000; in the Benburb Street district, 28.0 per 1,000.

Petition for an Inquiry de lunatico in the case of the Prisoner Edallj.

To The Right Honourable ARETAS AHERNS-DOUGLAS, M.P., Secretary of State for the Home Department.

WE, the undersigned, being duly qualified Medical Practitioners, do hereby humbly pray His Majesty's Secretary for the Home Department to institute an Inquiry into the State of Mind of the prisoner Edallj convicted recently of the offence of Cattle-Maiming at Wyrley, and that, if an educated man killed cattle in the senseless and purposeless manner under which the Wyrley outrages were committed, we submit he is, on primâ facie evidence, fitted for a lunatic asylum rather than a prison, and on that ground we pray for the above Inquiry.

MICHAELMAS TERM.

Literature.

INCE'S LATIN GRAMMAR OF PHARMACY. (a)
In these days when we hear so much regarding the neglect of prescription-writing, it is pleasing to find that this well-known manual has been called for. This proves, at all events, that it is still possible for medical students to learn how to write a prescription in correct Latin, if they will take the trouble to master the subject. The matter of this volume is divided into four sections. The first of these treats of Latin grammar as bearing on practical prescription-writing. This is, perhaps, the least interesting part, but it is none the less useful and instructive, and, moreover, is most essential as forming the groundwork of what follows. The second part deals with prescription-reading. Twelve typical prescriptions are fully analysed, and a number of others are given, both in contracted form and in unabridged Latin. English translations of the latter are given further on. Medical Directions are taken up in the third part of the work and are dealt with in a manner so minutely detailed that it is left in doubt whether the pupil can cultivate the art which only the older school of practitioners now seem to cultivate. We have much pleasure in adding our testimony to the many eulogies already passed upon this text-book. It certainly stands alone, and fills a place in the medical literature which otherwise would be vacant. The binding and printing call for a word of commendation in passing.

A MANUAL OF PATHOLOGY. (b)
"Costs' Pathology" has for long been a favourite manual among students since its first appearance in 1884. Professor Costs died at the beginning of 1889, and it must be admitted the edition edited by Professor Sutherland, and issued in 1900, left much to be desired. The present and fifth edition has been thoroughly revised by Dr. Sutherland, and may now be accepted as a trustworthy and fairly up-to-date introduction to the scientific study of pathology. We are glad, however, to find that the old dress is still maintained, but in size the volume has increased by 155 pages. The work is essentially one for the student of medicine, and this object the author has been steadily kept in view by the editor. Considerable alterations have been made, without materially interfering with the original plan of the volume. There has been some re-arrangement which will facilitate the profitable study of the book as a student's text-book. The chapter on Bacteriology has been altogether omitted, a step which we consider most unwise in a work intended to afford students a sure foundation for the scientific study of disease. The illustrations have been increased from 490 to 729, but still not a few of the old and unsatisfactory woodcuts are retained. Two coloured blood plates form a very useful and much needed addition.

Many of the new illustrations are of specimens in the Pathological Museum of the University College of Dundee.

We are glad to find that the concise references to the more important books and monographs on the subjects dealt with are still retained in their position at the end of the various sections.

The field of pathology is ever widening, and the horizon grows more distant, so that the student may remain undisturbed by the vast amount of new work that is destined to travel; but, ponderous though this work is becoming, it is likely long to remain the most popular of the one volumed works specially designed to meet the requirements of the student. It is certain that the appearance in the production of this, the latest and best edition of the Manual, may well be congratulated.

STEVENS ON MATERIA MEDICA. (a)
This author has altered the arrangement of the present edition of this work, so that instead of an alphabetical arrangement as he adopted in previous editions, they have been classified according to the pharmacological effect. The difficulties in the way of such an arrangement are obvious, and we do not know that there is anything in the present work that leads us to prefer such a grouping. The book has been thoroughly brought up to-date and will doubtless be of great value to American students of medicine.

As, however, the dosage and modes of preparation of drugs are radically different from those of the British Pharmacopoeia, the usefulness of the book in these countries is limited.

SWANZY ON DISEASES OF THE EYE. (b)
When a student inquires of his fellows or his teacher, "What is the best book on the eye?" the answer is undoubtedly in the majority of cases, "Swanzy." And the proof lies in the fact that the handbook has now reached its eighth edition. As is only natural, perhaps, the eighth edition (pp. 678) is a little larger than, say, the fifth edition (pp. 582). Herein lies a larger volume. For of large text-books on ophthalmology there are many excellent ones, but we know none as good as Mr. Swanzy's in its own particular class. So far Mr. Swanzy has succeeded very well to quote his preface to the fourth edition,—"in saying not all he might but all he ought." We may hope that the future editions of this book will be kept within reasonable bounds as the present.

This eighth edition has been revised throughout, and a good deal of fresh matter has been introduced. Of this new matter particular attention should be drawn to Kahnt's method of extirpating the lachrymal sac (Chapter XVII.), to the fuller account of ophthamitides (Chapter X.), and to the account of Mr. Maxwell's operation for shrunken sockets (Chapter XVIII.).

Kahnt's operation is a useful one which has been performed only too seldom in this country; and Mr. Maxwell's operation is a really good one for those cases in which it is indicated.

Mr. Swanzy's teaching is always clear and dogmatic and that is just what one wants in a handbook for students. The book is brought well up-to-date, yet notice might have been taken of the use of adrenaline chloride in hay fever, of scopolamine and ephedrine substituted for atropin when ocular disease occurs, of the X-rays in cases of Jacob's ulcer, and of cuprol in conjunctivitis. We have found misprints only on pages 280 and 641; but regret to say that the last three decades of the index became loose on little provocation.

A card of test-wools, explanatory of Holmgren's test for colour-blindness, and a Snellen's "Sunrise" figure, for testing astigmatism, are added.

Appendix No. 1 is devoted to Holmgren's method of testing the color sense and Appendix No. 2 to test of vision for the army, navy, &c. We would suggest

(a) "The Latin Grammar of Pharmacy for the use of Medical and Pharmaceutical Students, including the Reading of Latin Pharmacopoeias, Latin English and English-Latin Vocabularies, and Prosa." By A. A. Stevens, A.M., M.D., Lecturer on Practical Pharmacy in the University of London. London: Cadell and Strutt. 1862.

(b) "A Manual of Pathology." By Joseph Costs, M.D., late Professor of Pathology in the University of Edinburgh. Second edition, revised throughout by L. G. Sutherland, M.R., Professor of Pathology in the University of St. Andrews. Price, 1.25s., with 700 illustrations and 209 coloured plates. London: Longmans. 1862. Price 6s. net.
to Mr. Swanzey that it would be a convenience if he directed these various regulations in whatever cases he can.

The printing and binding (with the probably unique exceptions noted above) are very good.

RA D U M (a)

The contents of this extremely instructive and interesting brochure, while tending to elicit new surprises by displaying to public view some of the—till a few short months ago—not very unknown and unsuspected mysteries of the atom, do not mean to simplify the views of the initiated regarding the ultimate unity (or even identity) of all known physical agencies when traced back to their ultimate source. Radium pervades the earth beneath; and it permeates the waters under the earth. The movements of the omnipotent and omnipresent atom are really responsible for all the phenomena of the universal macrocosm, of which the human microcosm itself constitutes, metaphorically speaking, but an elementary atomic factor.

This booklet gives an excellent historical sketch of the discovery of the various phenomena of radioactive properties, up to the present time, from the text that the book is lucidly written and richly illustrated, its contents can be scanned without confusion of thought by every intelligent amateur in physical science. But the present item of interest to medical men begins on page 63:—"The Treatment of Disease by Ultra-violet Rays." We feel it to be our duty in this connection to offer our best thanks to the author, who is a distinguished member of another profession—fortunately for us in the present case one of the most purely physical in its methods and objects—for the spontaneous offer of the knowledge which he has thus gone out of his way to provide for us. Certainly it is not all that a smaller Canot is now a recommended text-book in preparation for certain "conjoint schemes" of examination, the attainments of the average medical practitioner in physical science still remain decidedly crude. And, as the "light-cure" is now the special feature of the most advanced scientific therapeuticists, it is quite a boon to have the latest up-to-date data thus placed before us, and in the clearest manners, by a master of pure physical science. The first illustration in this section is a reproduction of a photographic bust of Professor Niels R. Finsen, of Copenhagen—that true benefactor of humanity, who, for a long period, has shown himself a crusader against disease. Besides the lupus cure, the application of rays of various composition and analysis to small-pox, tuberculosis, &c., are here clearly described and critically examined. Needless to add, in concluding, that we hereby recommend this small volume to the notice of all our readers.

FIRST AID. (b)

This neatly-printed booklet gives a very clear and concise summary of the quality and quantity of knowledge which the proverbially intelligent denizen of the street should know, if he (or she) is ambitious to act the part of the Good Samaritan towards the victims of injury, or violence, of influenza, or elsewhere. We are told by the authors that each of the chapters into which the text is divided corresponds to the lectures set forth in the London School Board Syllabus.

At the end of each chapter three specimen questions are placed, "selected from those actually set in past examinations, together with suitable answers." Accordingly, the little volume is a professor's guide-book to the labyrinth of the Examination Hall; and having due regard to the standard by which it has been regulated, we think that it does credit to the judgment and selective power of the authors.

Medical News.

The Coming Bazaar in Aid of Mercer's Hospital, Dublin.

A most successful meeting was held on Friday last of the supporters of this hospital and patrons of the Mirus Bazaar and Fête under the presidency of the Duchess of Abercorn. The meeting took place in the Hospital and was largely attended. Mr. Charles Maunsell, Surgeon to the Hospital, submitted the report of the honorary secretaries, which related the history of the proposed. For the organisation of the bazaar and stated that the committee had obtained the use of the Ball's Bridge grounds for the week commencing May 21st, 1904. On those lines 300 stalls and 300 side shows" being actively organised, and in a flourishing condition in regard to monetary support. Thirteen of the counties of Ireland were up to the present represented by stalls, which were being run by well-known county ladies. Their ambition was to obtain 100 stalls and side shows, so every effort must be made to induce friends to take stalls. (Applause.)

Dr. L'Esprance Weddick read the report of the hon. treasurer, which stated that even at this early stage in the working of the bazaar the monetary prospects were most promising.

His Grace the Duke of Abercorn then proposed the following resolution: "That the Mirus Fête in aid of Mercer's Hospital is deserving of the support of all classes throughout Ireland, inasmuch as the hospital is one of the oldest institutions of its kind, and has been the means during almost two centuries of affording relief to a large and increasing number of patients from all parts of the country, as well as from one of the poorest districts of this city. Lord Justice Fitzgibbon seconded the motion, which was adopted. After a vote of thanks to the Duchess of Abercorn, the meeting came to an end.

Annual Meeting of the Pharmacal Society.

At the annual meeting of the Pharmaceutical Society in Ireland, the president, Mr. Beggs, had a very creditable record of progress during the year. The number of persons on the Register having risen from 1,483 in 1902 to 1,480 in 1903, and the year was closed with a balance to the credit of the society of £734 4s. 8d. An acrimonious discussion followed, in which Mr. Bernard accused the society of want of diligence in prosecuting offenders under the Sale of Poisons Act, and by way of protest he moved: 'That the report and accounts be adopted with regret,' which was defeated. Mr. Bernard again spoke, urging that the entrusting of prosecutions to the Royal Irish Constabulary was a mistake; but the heat of the discussion had not passed off, and the president called on Mr. Collie to "speak in sense," Dr. McWalter, then said that the society should request the Irish Local Government Board to give a preference to Irish-made chemicals and medicinal preparations, and the resolution was passed unanimously, and is reported on English-made matter by an English firm of printers. While the speakers on Dr. McWalter's resolution we learn that there are Irish wholesale manufacturers of chemicals and medicinal preparations; it is to be regretted that they do not advertise their wares better.

Royal College of Surgeons in Ireland.

The President, Vice-President and Council will, on Thursday, December 3rd, elect a professor of materia medica in the room of the late Sir George Duffey.
NOTICES TO CORRESPONDENTS.  
DECEMBER 20, 1893.

W.C.-4 p.m. Mr. Hutchinson—Clinique, (Surgical). 5.15 p.m. Dr. E. G. Little—Tuberculous Diseases of the Skin.

FRIDAY, DECEMBER 21ST.

HOSPITAL FOR DISEASES OF THE THROAT (Golden Square, W.).—4 p.m. Mr. Titley.—Diseases of the Nose.

MEDICAL GRADUATES’ COLLEGE AND POLyclINIC (22CHapman Street, W.).—4 p.m. Mr. W. Dodd—Clinique. 5.15 p.m. Mr. M. M. Pepper—Surgical.

WEST LONDON MEDICO-CHEMICAL SOCIETY (West London Hospital, Hammersmith)—8.30 p.m. Paper—Mr. F. H. Lind—Anæsthetics. Dr. Alex. Morian—Boliness in Treatment of Heart Disease.

Appointments.

JELLIS, A. W., M. R. Lond., Certifying Surgeon under the Factory Act for the Hinckley District of the county of Leicestershire.

JOHNSON, H. J., Physican to the Belfast Maternity Hospital.

JOYCE, FRANCIS JAMES, M.R.C.S., L.A. Medical Officer of Health for Dursley (Gloucestershire).

LINEY, R. H., M.R.C.S. Eng., L.R.C.P. Lond., Assistant House Surgeon to the Scarborough Hospital and Dispensary.

ROY, ALLAN C., M.R.C.S., L.R.C.P.I., Victoria, Junior House Surgeon to the Royal Eye Hospital.

SHRIFFMAN, T., L.R.C.P. Irel., Certifying Surgeon under the Factory Act for the Kilmainham District of the county of Wateford.

Vacancies.

BOURBONNEUTH.—The Royal Boscombe and West Hants Hospital. Surgeon. Salary £50 per annum, with board, lodging and washing. Applications to the Secretary.

Bridgewater Infirmary.—The Medical Officer of Health. Salary £80 a year, with board and residence. Applications to Mr. Edward Trevor, Honorary Secretary, Bridgewater Infirmary.

City of Nottingham.—Poor Law Infirmary. Second Resident Medical Officer. Salary £100 per annum, with furnished apartment, board, washing and attendance. Applications to G. M. Howard.

Durham County Hospital.—House Surgeon. Salary £125 per annum, with board and lodging. Applications to Wm. R. Wilson, Senior, 66 Saddler Street, Durham.

Dr. Stevens Hospital.—Visiting Physician to the Governors and Guardians of the Hospital. (See adv.)

Dr. Stevens’ Hospital—Gynaecologist. Applications to the Governors and Guardians of the Hospital. (See adv.)

Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £75 per annum, with furnished apartment, board, washing and attendance. Applications to S. J. Leonard, Clerk to the Board. (See adv.)

Jersey General Dispensary and Infirmary.—Resident Medical Officer. Salary £150 per annum, with board, washing, and attendance. Applications to the Honorary Secretary, Infirmary, Jersey.

Nottingham General Hospital—Physician. Salary £100 per annum, with board, lodging, and washing in hospital. Applications to the Secretary.

South Shields Union—Assistant (Resident) Medical Officer. Salary £200 per annum, with board, residence, and washing. Applications to the Union, South Shields.

Shibboleth Union. Royal Medical Officer. Salary £150 per annum. Application to J. Hopkins, Clerk of the Union, Oriel’s Office, South Shields.

Births.

GORDON WILSON.—On Nov. 25th, at Phillipsburgh Gardens, South Kensington, S. W., the wife of Dr. Gordon Wilson, of a son.

SHIPLEY.—On Nov. 6th, at Brookendine House, Armadale, Elginshire, James Herbert, 3rd. B., husband of Miss Herbert, F.R.C.S.Edin. of Rose Bank, Lancaster, of a daughter.

Marriage.

NEWTON.—On Dec. 5th, at the Mission Church, Loddislie, Henry Martin Newton, Esq., Surgeon to the Hospital, Jalahpur, India, and Alice Mary, daughter of Mr. Herbert, Col. P. E. Edelen, Indian Army (Bombay), of 15 Lansdown Road, Bedford.

Deaths.

KIRBY.—On Nov. 29th, at Cerne Abbas, Bournemouth, Emma Fredericka widow of the late Edmund A. Kirby, Esq., M.D., in her 89th year.

Original Communications.

THE 

EFFECT OF THE MID-WIVES ACT, 1902, ON 

IRISH TRAINING INSTITUTIONS AND NURSES. (a)

By ALFRED J. SMITH, M.D.R.U.I., F.R.C.S.I.,
Gynaecologist to St. Vincent's Hospital, Dublin; Professor of Midwifery, Catholic University, Dublin, &c.

GENTLEMEN,—I take this opportunity of tendering, on behalf of the Obstetric Section, our congratulations to Sir Arthur Macan for the honour conferred upon him by King Edward VII. We recognise that it was an honour well won. His worth is well known to us all. As the pioneer of rational gynaecology alone, he deserved well of his country.

I wish especially to draw your attention to the grave injustice that has been done to our midwifery hospitals and to our Irish trained midwives by the regulations drawn up by the Central Midwives Board, under the Midwives Act of 1902, and published on August 12th, 1903. I am not concerned with the details of the prolonged controversy which preceded this enactment, but I am concerned with what I consider an unwarrantable and unjustifiable slight on our Irish maternities—unwarrantable because uncalled for—unjustifiable because the training of Irish midwives is far superior to that required under the new Act.

I claim for myself to be in an exceptional position to speak on the subject. I have no official connection with any of these institutions, and can, therefore, speak with perfect freedom, in the hope that, by ventilating this grievance, justice may be done.

The general principles of the Act are five in number:—(a) That every midwife must be trained in strict accordance with the Act; (b) that she must pass an examination held by the Central Midwives Board; (c) that she must be cleanly in her person and attentive to her patient; (d) that she must not undertake the management of cases of abnormal labour; and (e) that she must keep careful record of all cases which she attends; principles that are in themselves excellent. It is with the details I find fault. In regulating the course of training the first Clause is:

—No person shall be admitted to an examination unless she produce certificates that she has undergone the following course of training:—

1. She must have attended and watched the progress of not fewer than twenty labours, making abdominal and vaginal examinations during the course of labour and personally delivering the patient. (Schedule, Form IV.)

2. She must have, to the satisfaction of the person certifying, nursed twenty lying-in women during the ten days following labour. (Schedule, Form IV.)

The certificates as to (1) and (2) must be in the form prescribed by the Central Midwives Board, and must be filled up and signed either by a registered medical practitioner, or by the chief midwife, or, in the absence of such an officer, by the matron of an institution recognised by the Board, or, in the case of a Poor-law institution, by the matron being a midwife certified under the Midwives Act, or a superintendent nurse certified in like manner, and appointed under the Nursing in Workhouse Order, 1897, and attached to such an institution, or by a midwife certified under the Midwives Act, and approved by the Board for the purpose.

3. She must have attended a sufficient course of instruction in the subjects named below:—

——No period of less than three months shall be deemed sufficient for the purpose. The above certificates must be in the form prescribed by the Central Midwives Board, and must be filled up and signed by a registered medical practitioner recognised by the Board as a teacher. (Schedule, Form V.)

Will it be believed that the very first clause relating to the training has the effect of rendering any nurse who has been trained at our great Irish maternity hospitals ineligible?

The fact remains that a woman who spends three months in acquiring a knowledge of midwifery "under supervision satisfactory to the Central Midwives Board" will be eligible for admission to the roll, while a nurse who has spent six months in our world-renowned hospitals is not only ineligible, but considered unfit even to present herself for examination. The provisions in the Clause which shut out nurses trained in Irish hospitals are two in number:—In the first place it is made mandatory that she must attend and personally deliver twenty cases of labour; in the second place, she must nurse twenty cases for ten days after confinement. It is impossible for hospitals such as the Rotunda, the Coombe, the Holles Street, in Dublin, to give twenty cases to a nurse for personal conduction; because, to do

---

(a) Read before the Obstetric Section, Royal Academy of Medicine in Ireland, November 27th, 1903.
so would necessitate doubling the size of the hospitals. It is equally impossible to enable a woman to nurse the patient for ten days following labour, because the patient leaves the hospital at the eighth day, and would not remain longer even if the hospital authorities could keep her.

How Irish Midwives Are Trained.

Of the thirty-eight lying-in hospitals situated in Great Britain and Ireland, Queen Charlotte's, London, is the only one that at all approaches in size our three great maternities. We have, as is well known to you, three lying-in institutions, each holding a Royal Charter for the express object of training, examining and certifying midwives——The Rotunda, whose Charter was granted over one hundred and forty years ago, the Mater, whose Charter was granted in 1867; and the National, of Holles Street, which received its Charter in 1903.

The course prescribed by our maternities for the training of pupil midwives is practically on the same lines.

The period of study is six months (or for those who can show evidence of three years' satisfactory training in an approved general hospital, three months), at the conclusion of which time, if they have done their nursing to the satisfaction of the lady superintendent, they are examined as to competency before the Master and assistants, at which they must receive not less than 50 per cent.

of the fee.

The pupil midwife must have attended a theoretical course of lectures by the Assistant Master, and she must have been present at the clinical lectures delivered in the wards, where modern methods of examination are taught, and conduct of labour is practised under the most approved principles. Special instruction by 60 masters or staff sister is given on purely nursing duties, such as the preparation of the beds for the patient, the bathing and feeding of the infants, and on the important matter of invalid cooking.

We all know the raw unpromising material the majority of expert midwives are made of. Can anyone in reason suppose a midwife trained after the British system with a nurse certified by the three months' midwifery approved of by the Central Midwives Board, who spends only three months in acquiring a knowledge of midwifery?

The excellence——nay, the necessity——of our Irish system keeps women who have had no previous training as nurses, who have, on the contrary, septic ways, continually under observation and training, till the doing of things right becomes a second nature. If such a woman before she is trained passes under the influence of a nurse of strong personality who sneers at innovations or established methods, there is no limit to the harm that may be done.

I agree with Professor W. J. Sinclair, a member of the Central Midwives Board, that the first object to be gained in the training of midwives is to provide the best possible nurse for lying-in women of the poorer classes of the community, in order to prevent not only childbed accidents, but mortality. Of childbed accidents the public are but too well aware, but of the mortality that public know little or nothing. The philanthropic visitor vaguely comprehends it. It is the gynaecologist who knows it in detail. The chronic sickness following an infection or accident of childbed is too often the source of impoverishment and distress in families of working men, who would be otherwise comfortable and independent on a living wage.

A good midwife, then, I take it, must be able to conduct a normal labour, to recognise abnormal conditions, be aseptic in her habits and ways, kind and attentive to the patients under her charge.

Under which system, I ask you, can this ideal nurse be trained, whether the six months' hospital system of the Irish Chartered institutions, where the confinements that come under notice can be counted in hundreds, or the three months' midwifery system required by the Central Midwives Board? I do not think there can be any doubt that the answer will be——the Irish system.

Is this injustice to Irish institutions and midwives inevitable? I leave the expression of opinion to you.

In March of last year, 1902, the Royal College of Physicians of Ireland drew attention to the serious injury which would be inflicted upon Irish training institutions should the Midwives Bill, then before Parliament, be enacted in its present form. The promoters of the Bill gave, during the Committee stage of the Bill, the assurance to those interested in the Irish hospitals that nothing would be done that would interfere with the rights of Irish trained midwives. And this is how that assurance is carried out.

Irish institutions, although not excluded by name, are asked to do what is impossible.

The Dublin midwifery hospitals are, and it is in no boastful spirit that I say it, among the first midwifery hospitals in the world——offering advantages to both students and midwives that cannot be obtained in any hospital in the United Kingdom. We have held this proud position for over a century, attracting men from all parts of the civilised world. As an instance of the place it holds in the minds of outsiders, in the American guide book to students, Dublin is recommended as the place to study midwifery.

Viewing the matter how one may, to my mind there is only one conclusion justifiable, namely, that nurses trained for six months in Irish midwifery hospitals are far superior to the average woman who will present herself for examination after having fulfilled the three months' midwifery tutelage required by the Central Midwives Board.

The present regulations of the Central Midwives Board act, as I have pointed out, unfairly and harshly against our midwifery institutions and their trained midwives.

It may not be generally known that a considerable number of English women have up to this availed themselves of the many advantages to be obtained in our midwifery hospitals, and have elected to be trained there; and that many Irish nurses leave Ireland every year to practise among their kith and kin in England. Now this must all go because our midwifery institutions cannot honestly comply with the regulations as required by the Central Midwives Board.

My point, and I hope, gentlemen, you will agree with me, is that nurses who have obtained their certificates from our three Chartered hospitals shall be at least entitled to be admitted to the examination of the Central Midwives Board without having to spend a further three months in England. I am glad to see so many representative obstetricians present, and, contrary to the usual custom, I invite a discussion on my address in the hope that more light may be thrown on this important subject, and that a way may
be pointed out to secure a modicum of justice to our Irish Chartered hospitals.

THE PHARMACOLOGY OF THE SAPONINS,
ILLUSTRATED BY DIAG RAMS AND TRACINGS SHOWING THE EFFECT OF VARIOUS SAPONINS UPON THE MUSCLES, BLOOD-VESSELS, AND ISOLATED HEART. (a)

By Professor R. B. WILD, M.D., M.Sc., M.R.C.P.Lond., Lecturer on Materia Medica, Owens College, Manchester, &c., &c.

The saponins form a group of glucosides which are widely distributed in the vegetable kingdom, and have been found in over 150 species of plants, of which the most important are the Quillaia saponaria, which is official in the barb.; the soapwort, or soap-plant; the Cyclamen europaeum or sow-bread; the Agrostemma githago, or corn cockle; the Falygalla senega, the Hemidesmus indica, the Digitalis purpurea, and the various species of smilax known as sarsaparilla. Though known from the early part of the nineteenth century, our knowledge of the constitution and properties of various saponins is largely due to the work of Kober and his pupils at Dorpat during the last twenty years. They find that most of these bodies belong to a series having the general formula, CnH2n - 8010, and the more important seem to have the "n" equal to 17, 18, 19, or 20. Some of these bodies form salts with alcohols, and all may be decomposed by hydrolysis into glucose and pharmacologically inactive bodies, to some of which the name sapogenin has been given.

The saponins themselves vary greatly in their pharmacological activity; the most powerful are called sapotoxins, and under certain conditions they may be converted into inactive saponins without losing their other properties, such as the power of causing frothing in watery solutions (from which the name of "saponin" was derived) or that of forming emulsions.

Kober has shown that in quillaia bark there are two active saponins, quilliac acid, and quillia-sapotoxin; and an inactive substance, lactosin. The two former are general protoplasmic poisons and direct local irritants. When administered by the mouth in sufficient doses they act as irritant poisons, but are not absorbed when there is no lesion of the mucous membrane. Administered subcutaneously or intravenously, small doses produce death. When locally applied they cause paralytic action on the muscle and of the isolated heart, and even in minute doses have a peculiar action on the blood which results in destruction of the red blood corpuscles and laking.

A more detailed study of the action of these saponins, which has been carried on in the Pharmacological Laboratory of the Owens College, shows, however, that the paralyzing action upon muscular tissues is preceded by a variable period of irritant action, and that even a very dilute solution is able to produce some spasm of all contractile tissues.

An isolated muscle of a frog is killed by a 1 in 10,000 normal salt solution of quillaia sapinon in two hours, with considerable contracture, and the action can be traced even in a dilution of 1 in 100,000.

One of the most marked actions of all the saponins we have so far examined is their power of causing contraction of the blood-vessels in the tortoise and frog after destruction of the brain and spinal cord. A normal salt solution, containing 1 in 50,000 of either quilliac acid or sapotoxin will cause an almost complete stoppage of the flow within a few minutes. On the isolated frog's heart in Roy's apparatus a most characteristic effect is produced; the beats become quicker, there is a fall in the height of contraction but a more marked diminution in the degree of relaxation, so that the heart remains in a partially contracted state and gives small regular beats without becoming fully relaxed. If the solution of the saponin is a strong one it will stop quickly in a contracted state, but if weaker the muscle becomes gradually paralysed and the heart finally dies in a diastolic condition. This characteristic reaction can be traced even in a dilution of 1 in 500,000 of the saponin. Weaker solutions usually cause irregularity and paralyse the heart muscle without any contracture. The infusion and tincture of quillaia act in exactly the same manner as the active principles, but with very dilute solutions of the latter a distinction can be found between the effect of quilliac acid, which causes more spasm, and quillaia sapotoxin, which causes less spasm but is more toxic.

A number of experiments were detailed to show the effect of the digestive ferments upon the quillaia saponins, and also to trace their excretion from the body. With respect to other drugs, senega and sarsaparilla preparations, digitalis infusion, and digitonin have given similar, though weaker effects.

In view of the toxic properties of quillaia it is most desirable to consider whether the growing practice of using preparations of this drug as a supposed harmless emulsifying and suspending agent is justifiable. Certainly they ought never to be used if there is any reason to suspect a lesion of the gastric or intestinal mucous membrane or if it is so often the case where bismuth or rhubarb mixtures are given, and to which quillaia is, I believe, sometimes added, even when not ordered in the prescription. It would be worth trying whether some inactive saponin, such as the so-called barya saponin, could not be used for this purpose in place of the more toxic preparations.

A second point worthy of further clinical investigation is the question of the value of the saponin-containing drugs in the treatment of tertiary syphilis. Soap-plant, hemidesmus, sarsaparilla, and quillaia have all enjoyed more or less reputation for this purpose, and from the results of certain experiments we have made as to the activity of sarsaparilla there seems reason to suspect that the crude drug deteriorates by keeping, and that old samples may be entirely inert.

A third point is that it is hardly correct to speak of the saponins as antagonists to digitalis or of digitonin as an inert saponin. There is, in fact, a considerable resemblance between the actions of digitalis and saponin as regards the slowness of absorption, the power of contracting vessels, and the spasmotic contraction of the cardiac muscle, though the slowing of the beat and the prolongation of systole produced by digitalis are not seen as the effect of saponin. The infusion of digitalis

(a) Read at a meeting of the Therapeutical Society, Tuesday, November 8th, 1903.
and digitonin in our experiments has given tracings showing the characteristic saponin action on the heart, and that the fresh infusion is considered by many clinicians to be the best preparation of digitonin, it is worth remembering that digitoxin is insoluble in water, and that the evidence that it may be dissolved by the very soluble digitonin, as assumed in some text-books, is inconclusive. This important question is now under investigation.

THE BOTANY OF THE INDIAN ACONITES. (a)

By Dr. O. STAPF, Ph.D., Principal, Botanic Gardens, Rishikesh.

Indian aconites are mentioned in some of the oldest Sanskrit pharmacopoeia. Their reputation as powerful poisons and therapeutic agents spread early to the medical schools at Alexandria and Bagdad, and has continued through many centuries down to the present in the Persian and Indian pharmacopoeias. The first attempts to cultivate those drugs to the plants that yield them were made by Buchanan, Hamilton, and particularly by Wallech, in the beginning of the last century. The Indian aconites come under two categories, viz., poisonous and non-poisonous species. The active principles of the former are allied and similar in their physiological effect to the aconitine of the European Aconitum napellus, whilst the latter are used essentially as tonics. Both kinds are the tuber-like roots which are sold in the drug shops of India. The poisonous tubers are generally known as "Bish," or "Bick," from "Visha," Sanskrit for poison. They are brought to the plains of India from the sub-alpine and alpine regions of the Himalaya almost throughout its length, but principally from the Central parts, that is, from the Sutlej River to Sikkim, and above all, from Nepal. In 1818-19, Wallech procured from native collectors complete specimens of an aconite said to be the Bhik plant of the Nepalese, and two years later he collected it himself on the mountains to the north of Kathmandu. He sent specimens to Europe, and some of them were described as A. ferox by Seringe, of Geneva. Subsequently he received more specimens from Nepal, Kumaon, and Surnoor, all stated to be Bhik plants. Unfortunately, though aware of certain structural differences, he conjectured that they were all states of A. ferox, due to different conditions of habitat. His assumption remained practically unchallenged, and A. ferox became as vague and general a term as the vernacular "bish." Certain discrepancies in the chemistry of different samples of A. ferox which Professor Dunstan examined, led to the critical revision by Dr. Stapf of the herbarium material of the so-called A. ferox at Kew, Calcutta, Edinburgh, &c., with the result that it proved to be a collection of species. At the same time, Professor Dunstan's researches, which were carried on independently, have shown that several of those components of the old A. ferox are also chemically distinct, yielding distinct alkaloids. Dr. Stapf pointed out that the original A. ferox described has not been collected again since Wallech, nor do its roots seem to occur in commerce, so that accordingly nothing is known about its chemistry. The so-called Nepal aconite, as it was imported into England in the fifties or sixties, was A. spicatum (A. ferox, var. spicatum Bruhl) from Nepal and Sikkim. It yields, no doubt, the bulk of the "Bikh" of the Calcutta bazaars. West of Nepal, Kumaon possesses an aconite from which a considerable portion of the "Bikh" of the North-Western Provinces is derived, the A. Balfourni (A. ferox of J. Balfour, not of Seringe) and the A. ferox, var. atroxx, and partly variety polyphyllous of Bruhl, whilst Garwal and Baisin provide another species, A. demorhizum (A. ferox, var. atroxx Bruhl) partly, the roots of which are likewise collected and used in a similar way. Comparing those species with Professor Dunstan's table of Indian aconite alkaloids, we find that A. spicatum is characterised by Bikhaconitine, A. Balfouri and A. demorhizum by Pseudaconitine. The roots of another poisonous aconite have been sold for a considerable time in the Punjab. They came from the mountains north of Peshawar, and were referred erroneously to A. napellus. They belong, however, to a very distinct species, A. chasmanthum, A. napellus, var. Bruhl, characterised chemically by the new alkaloid indacotonine; whilst the true Aconitum napellus has so far not been observed in India.

Dr. Stapf referred finally among the non-poisonous species to one which is particularly interesting as being the source of the reputed Judum Kuthar, the "zedoar" of the ancients, a famous and highly prized antidote. It is only known from its tubers, which to every respect resemble those of A. heterophyllaides (A. ferox, var. heterophyllaides Bruhl), a species found in East Nepal and Sikkim. There are over twenty distinct species of aconitum in India, so that Professor Dunstan has still a wide field before him in working out their chemistry.

AGORAPHOBIA

AND SOME ALLIED CONDITIONS. (a)

By A. L. HUSBAND, M.B., C.M.Edin.

After defining the three conditions known as agoraphobia, claustrophobia, and acrophobia, and giving an epitome of literature on the subject, Dr. Husband related cases he had met with and studied during a period of over seven years. In all some forty cases had been collected, and the following generalisations formed from them:—

1. In all the cases of agoraphobia and claustrophobia there were errors of refraction.

2. That in cases of neurasthenia and hysteria these conditions do not obtain if refraction be normal naturally, or rendered so by proper correction.

3. That all these conditions became exaggerated immediately any low state of general vitality was encountered, and were frequently detected when treating this condition.

After carefully going into the probable etiology of the conditions from the optical, physiological, anatomical and physical standpoints, he draws the following conclusions:—

1. Agoraphobia, claustrophobia and acrophobia are more or less allied conditions attributable to analogous causes.

2. Agoraphobia and claustrophobia are directly

(a) Paper read at a meeting of the Therapeutical Society, Tuesday, November 5th, 1895.

(b) Abstract of paper read at the Sheffield Medico-Chirurgical Society, November 16th, 1895.
were unsuccessful, and naturally so, for examination showed he had locomotor ataxy, and the vomiting was due to gastric crises.

Gastric crises are usually the only ones to occur early in the disease, but I saw a case under the care of Mr. Bowdy where laryngeal crises were so severe as to necessitate tracheotomy proved to be the first symptom of locomotor ataxy.

Case III.—A man, aged 40, came on May 7th, complaining of a suppurating corn on the right foot which had the appearance of a perforating ulcer. He had a "girdle sensation" sometimes, and occasional "moving pains" in the legs. Twenty years ago he had syphilis. His pupils reacted normally to light and to accommodation, and the optic discs were normal. There was no ataxia on ordinary movements, but he could not toe and heel a line, and he swayed slightly on standing with closed eyes. He found it difficult to turn quickly. His knee-jerks were absent. There was occasional incontinence; the urine contained no sugar.

On May 14th he had much swelling of the left thigh and knee, which pitted on firm pressure, and enlargement of the veins right up to the pelvis. The swelling was quite painless.

On May 28th the left knee-joint was unduly mobile, and could be displaced laterally. The articular surfaces could be felt to slip. He now had the Argyll-Robertson pupil.

Remarks.—The interest of the case lies in the development of both the Argyll-Robertson pupil and Charcot's disease of the knee within the three weeks this patient was under observation. Pain in the shoulder and distal end of the whole limb is the typical mode of onset of Charcot's disease. It is usually considered a late complication of tabes, but Charcot himself maintained that it occurred most commonly in the earlier stages and before the onset of ataxia, as it did in this case.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXIII.

FrittON SANATORIUM, NORFOLK.

NORFOLK is an excellent county for a summer station, but popular opinion does not view it with conspicuous favour as an all the year round resort for the invalid. Its general surface is undulating, and there is but little shelter from exposure to winds, and those from the east and north-east are certainly trying except to those in vigorous health. Considerable cold is experienced, especially in winter and early spring. The air, however, is clear and dry, and but little fog occurs; the rainfall is considerable, much sunshine is enjoyed, and the climate is bracing.

It is firmly held by not a few that East Anglia presents many features suitable for the hygienic treatment of pulmonary consumption. Certainly several sanatoria have been established in this district, and are accomplishing much good work.

As we have already shown in this series of articles, there is now no lack of admirable sanatorium accommodation in this country for consumptives belonging to the wealthy and well-to-do classes; but for those of slender means it is at present exceedingly difficult to find desirable institutions.

Efforts are being made to meet this want at least in some measure by the establishment of what may be, perhaps, best termed hygienic homes.

An excellent example is to be found at The Beeches, now known as Frittton Sanatorium, Long Stratton, in Norfolk, and conducted by Dr. Mary Smith. The building is a picturesque and old-fashioned farm-house, which, without much structural alteration, has been modified to meet modern requirements for a so-called "natural" treatment of consumption. The house stands on gravel subsoil, is moderately sheltered, and the rooms, although necessarily somewhat of ancient form, seem to have been wisely arranged and have been inspected the apartments and grounds devoted to the
patients. Accommodation can be provided for five or six patients, and, of course, comparatively early cases are desired.

There is a large, pleasant and well-sheltered garden with revolving shutters, in which the patients spend the summer, and hot meals in some instances are also served. As far as possible the patients spend the whole day in the open.

Dr. Mary Smith, the resident physician, personally supervises the details of treatment for each individual case; and as the number of cases is small, the comfort, convenience and medical care of every patient should be thoroughly satisfactory. The matron is a trained and experienced nurse. Fritton Sanatorium has been opened for two years.

After a careful inspection of the establishment and inquiry into the manner and method of its conduct, we are of opinion that the treatment may be considered efficient and the accommodation comfortable.

We were informed that the ordinary routine of the day consists of breakfast at 8.30, followed by rest for one and a half hours, regulated exercise from 10.30 to noon, lunch at one o'clock, with an hour's rest before and after. Exercise is taken when possible in the afternoon, and dinner is at 7 o'clock. Temperatures are taken three times a day by the oral method.

The sanatorium occupies a somewhat isolated situation. It is four miles from Forncett Station, which is on the main line of the Great Eastern Railway, ten miles from Norwich, and one hundred from London, but can be reached by train in about two and a half hours from Liverpool Street. By arrangement, a carriage will meet any train. The telegraphic address is "Beecroft, Hempnall." The full postal address is "Fritton Sanatorium, Long Stratton, R.S.O., Norfolk." The terms, as we have already indicated, are intended to meet the wants of those to whom financial considerations are of importance. The fees are £2 from two to three guineas a week, inclusive of everything except personal laundry.

We think by the addition of a few suitably restricted bungalows or sleeping shelters the work of the establishment might be advantageously extended. It would probably add to the popularity and usefulness of the sanatorium if arrangements were made whereby regular inspections were made by a visiting physician.

Hygienic homes, such as the Fritton farm-house sanatorium, may well be multiplied in various parts of the country, so not only securing rational treatment for many needy cases, but fulfilling an important function in educating, in some measure at least, the non-progressive and essentially non-hygienic rustic of this land.

Transactions of Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, NOVEMBER 6th.

The President, Dr. Seymour Taylor, in the Chair.

Dr. Herbert Tilley showed (1) a case of chronic suppuration of accessory nasal sinuses caused by operation. The patient, an unmarried woman, st. 41, had suffered from profuse purulent nasal discharge for about six years, the condition becoming worse during the winter. She had been complaining of enteric fever. For about five years headache had often been so severe as to preclude the performance of her duties as a professional nurse, while mental apathy and the desire to concentrate her mind on her work had been a more or less constant symptom. During this time polypi had on several occasions been removed from the nasal cavities without producing any effect on the discharge from the nose. On January 12th of this year Dr. Tilley operated on both frontal sinuses by completely removing the anterior wall, curving away the polypoid pyogenic membrane and making a large opening into the nose by way of the fronto-nasal canal. The ethmoidal and sphenoidal cavities were also dealt with at the same time by curettage. On January 18th the maxillary antra were opened through the canine fossa, the diseased contents cured away, and the sinus cavity mopped out with chloroform (ad 3) and slightly packed with bichloride gauze. At the end of twenty-four hours the gauze was removed and not reinserted, the antral cavities being irrigated with warm boracic lotion, dried and left to air dry to the nose. The operation was carefully watched, and just before the openings in the canine fossa closed it could be demonstrated that the antral cavity was practically filled of a circulating fluid. The patient has now been free from any discharge for over seven months, her general health has been better than it has been for years, and she has increased 17 lb. in weight. There is practically no scarring over the frontal sinus regions.

The President considered that the chief interest in the case, apart from the extensive and general suppuration of the accessory sinuses, lay in its association with enteric fever, and referred to the extremely varied nature of the complications and sequelae of that disease.

Replying, to a question by Mr. Garry Simpson, Dr. Tilley stated that he did not consider that the suppuration had been started by the typhoid bacillus. Probably the antra had been suppurring before the enteric fever, and the low state of health induced by that disease brought about a rapid infection of the other accessory nasal sinuses.

Dr. Herbert Tilley showed (2) a case illustrating an experimental preparation for the relief of almost complete adhesion between the soft palate and the posterior pharyngeal wall, the result of typhoid pharyngitis. The adhesion was so complete that only a small probe could be passed from the oro- to the naso-pharynx. The patient, a girl, st. 23, had been operated on twice previously, but re-adhesion had occurred on each occasion. After a preliminary laryngotomy Dr. Tilley completely divided the adhesions between the palate and the pharynx. A strong silver wire was then passed from before backwards through the soft palate close to its junction with the hard palate, about half an inch from the middle line. The distal end of the wire was then made to replace the soft palate close to its free margin and from behind forwards, so that a short segment of the wire rested on the posterior surface of the soft palate. The free ends of the wire were then passed through a needle behind forwards so as to come out through the soft tissues of the upper lip just below the incisor tooth, firm traction exerted on the palate, and the wires twisted upon one another and cut off short in front of the tooth. A similar procedure was repeated on the other side of the palate. The incisors were cut out in about a fortnight, and by that time the raw surfaces (corresponding to the previously adherent areas) had become practically covered with epithelium, and hence no re-adhesion took place.

Mr. McAdam Eccles, Dr. Tilley stated that he had closed the laryngotomy wound at once. A certain amount of subcutaneous emphysema followed, affecting the right side of the face and neck, but this disappeared in about a week.

Mr. McAdam Eccles showed a case of sarcoma of the os pubis occurring in a girl, st. 11. Four months previously pain in the right leg, chiefly in front of the knee, had been complained of. At that time an abdominal swelling. When the swelling appeared operation was advised, but declined, and the tumour had rapidly increased in size. The patient was fairly nourished and could stand and walk without discomfort. In the hypogastric region there was a large globular swelling, hard, fixed and somewhat overlapping the body of the os pubis. Part of the tumour to the left side was softened. The inguinal glands were enlarged. Rectal examination showed the details of treatment by removing both frontal sinuses by completely removing the anterior wall, curving away the polyedoid pyogenic membrane and making a large opening into the nose by way of the fronto-nasal canal. The ethmoidal and sphenoidal cavities were also dealt with at the same time by curettage. On January 18th the maxillary antra were opened through the canine fossa, the diseased contents cured away, and the sinus cavity mopped out with chloroform (ad 3) and slightly packed with bichloride gauze. At the end of twenty-four hours the gauze was removed and not reinserted, the antral cavities being irrigated with warm boracic lotion, dried and left to air dry to the nose. The operation was carefully watched, and just before the openings in the canine fossa closed it could be demonstrated that the antral cavity was practically filled of a circulating fluid. The patient has now been free from any discharge for over seven months, her general health has been better than it has been for years, and she has increased 17 lb. in weight. There is practically no scarring over the frontal sinus regions.

Mr. McAdam Eccles showed a case of sarcoma of the os pubis occurring in a girl, st. 11. Four months previously pain in the right leg, chiefly in front of the knee, had been complained of. The patient has now been free from any discharge for over seven months, her general health has been better than it has been for years, and she has increased 17 lb. in weight. There is practically no scarring over the frontal sinus regions.

Dr. Furniss Potter showed a case of radical masto
operation in which rapid healing took place without skin grafting. The patient was a girl, aged 14. Operation was rendered urgent by the acceleration of acute or chronic middle ear trouble. The operation was performed with great safety, without perforation of the antrum, and the patient made a good recovery. The ear was much softened. The case did well until the eighth day, when a severe attack of erysipelas, lasting eighteen days, occurred. Thereafter the patient made a good recovery, and two months after the operation healing was complete. It is considered this an unusually good result, and quoted Mr. Ballance’s statement (Lancet, April 11th, 1903) that the average time necessary for complete healing in cases similarly treated is six to seven months.

Dr. E. A. Saunders showed a case of rickets with aneurysm and great enlargement of the spleen. The patient, a boy, aged 9, had been admitted to hospital five weeks previously, complaining of abdominal pain and shortness of breath. The most striking features of the case at that time were an intense anaemia together with very great enlargement of the spleen, and, to a less degree, of the liver. The head was large and square, with marked bossing of the temporal and parietal regions. There had been no recent illness, and the family history showed nothing of importance. On examination of the blood the anaemia was found to be of simple type, the red corpuscles being 1,780,000 and the white 5,000 per c.mm. The haemoglobin was about 40 per cent. The spleen reached to the middle line well below the umbilicus, and the liver could be felt 24 inches below the costal margin. There was no lymphatic enlargement, no purpura, no hemorrhages, no oedema and no rise of temperature. Under a tonic treatment consisting of arsenic, iron, and cod-liver oil, together with good food, the improvement was extremely rapid. The red blood corpuscles had increased to 3,860,000 and the white 11,000 per c.mm., and the haemoglobin had risen to 75 per cent. The anaemia had practically disappeared, and both the liver and spleen had decreased in size.

Dr. Dudgeon urged the importance of a complete examination of the blood with differential count of the leucocytes, in such cases, and referred to the fact that the enlargement of the liver and the spleen might be more apparent than real.

Mr. Keetley showed (1) a case of extensive contracture after severe burns; (2) a case of carotid aneurysm in a woman.

THERAPEUTICAL SOCIETY.
At the general meeting held November 24th, at the Apothecaries’ Hall, Professor R. B. Wild read a paper on “The Pharmacology of the Saponins,” illustrated with diagram and tracings, which will be found on page 635.

Professor Wyndham Dunstan, F.R.S., gave an account of the chemical investigations now proceeding at the Imperial Institute at the instance of the Government of India, of the various Indian aconites and their alkaloids. The properties of the three distinct aconites which had been isolated from the three characteristic aconites known in European medicine were first noticed: Aconitine from Aconitum napellus, japonicum from Aconitum japonicum, or Fischeri, pseudoaconitine from the Aconitum ferox, usually found in European commerce. These three alkaloids, though chemically different, belong to the same type, and exert a physiological action which only differs in degree. The Indian aconites contain series of Aconitum napellus and Aconitum ferox, which have been so far examined by Professor Dunstan and Mr. Andrews have furnished pseudoaconitine and two new alkaloids, which have been named indoxalan and isoxaline. In chemical properties and physiological action and toxicity the new alkaloids closely resemble pseudoaconitine. The botany of these aconites has been studied at the Kew. Professor Cash F.R.S. A descriptive paper by Dr. Stapf will be found on page 636.

NORTH OF ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY.
MEETING HELD AT SHEFFIELD, NOVEMBER 20TH, 1903.

DR. J. E. GEMMELL, President, in the Chair.

SPECIMENS.
DR. JOHN W. MARTIN (Sheffield) showed some rounded bodies removed from a single woman, aged 41, in whom an exploratory incision revealed a large fibroid tumour on the peritoneum generally, and not at the point of entry of the uterine vessels. The tumour was completely removed by simple excision, and the cure was followed by complete relief. There was no adhesion.

Professor Arthur Hall (Sheffield), who examined the tumours, said that they possessed distinct capsules out of which the contents could be shelled. Within the capsule were others, and in the interstices lay large oval pigmented bodies like the cells of melanotic sarcoma. Regarding the nature of these, the appearance suggested hydatid, but they were manifestly actively growing, and showed no evidence of hydatid. They might be ova or deposits of pigment, but he had an open mind as to the precise nature of the growth.

The President asked if hooklets had been found.

Dr. R. Favell (Sheffield) said he had been present at the operation. The main growth was an ordinary fibroid tumour, and in his opinion unconnected with the smaller growths, which, he thought, sprang from the peritoneum.

Dr. Lloyd Roberts (Manchester) inquired if emaciation was present.

Dr. Martin, in reply, said no hooklets had been found, nor was emaciation present. The fibroid was about the size of a man’s head.

Dr. W. Walter (Manchester) showed (1) an ovarian cyst with pedicle twisted two and a half times, without change in cyst wall or contents. (2) Fibroma of uterus removed by supra-vaginal hysterectomy. It was interstitial in position, and its connections did not allow of enucleation. (3) Multiple fibromata of uterus, extending, involving lower uterine segment, as well as fundus. Supra-vaginal hysterectomy was rendered difficult by the existence of pelvic impaction.

CASES.
Dr. T. B. Grimsdale (Liverpool) read notes of a case of sloughing submucous fibroid of the uterus projecting through the cervix, treated by abdominal hysterectomy, and showed the specimen.

The President remarked that on the question of the route employed, the choice must lie with the operator. He thought he would have adopted the vaginal route in this case.

Dr. W. Walter said the keynote was the size of the vagina. When the latter was small he considered that the risk was less if laparotomy were carried out. He asked whether in Dr. Grimsdale’s case it would not have been better to remove the sloughing part of the tumour per vaginam in the first instance, and then proceed per abdomen. Regarding infection of the laparotomy wound, he said it was astonishing how rarely it follows in operations for pyosalpinx when the wound is carefully protected by packing.

Dr. Lloyd Roberts thought Dr. Grimsdale had adopted the best route possible in his case. If the vagina allowed of rapid removal then that route would have been preferable. He emphasised the necessity for preserving the uterus if possible, and suggested that the uterus might have been opened, the tumour emulated, and the uterus sewn up and saved for the performance of its natural function.

Dr. E. C. Croft (Leeds) said that Dr. Grimsdale had obviously adopted the only course possible. Was there any infection when they had removed the uterus by the vaginal route in the first instance? If so, had they considered that the infection was due to the post-operative foul discharge?

Dr. Grimsdale, in reply, said he should feel inclined to attack any fibroid per abdomen, unless vaginal pressure was extreme or the abdominal pressure of operation; when sepsis already existed delayfavoured infection. It would have been quite possible to remove the sloughing part per vaginam in the first
instance, but no advantage could have accrued, as the whole of the uterine cavity was septic. No slough was seen in the vagina. As no peritoneal infection occurred, he thought it possible that skin might be more liable to infection.

Dr. T. F. Fowell (Sheffield) read notes of the following:—(1) Vesicular mole passed the day after admission to hospital, by a married woman, aged 21. Two small purplish growths of the size of raspberries were excised from the anterior vaginal wall. Palpation of the uterus showed that the mole was of the destructive variety. The patient made a good recovery. Three cases of uterine tumours: (1) Submucous fibroid removed from a woman, aged 33, manifesting no watery discharge and menorrhagia. (2) Degenerating submucous fibroid. Patient, aged 50, two children, youngest being twenty-three. Menopause at 47; watery discharge for three years; abdominal pain for a few months. (3) A case of tumour, probably sarcomatous in nature, removed on the same day. Patient, aged 37; married eleven months. For the last few months herself pregnant, as the patient has been getting larger, and pressure symptoms were present; menstruation regular; profuse. Dr. Fowell also showed the specimens.

In the ensuing discussion, the President and Dr. Lloyd Roberts suggested that the first case seemed to be a favourable one for performing Cesarean section of the fibroid, the latter holding that this was perfectly justifiable in a woman in the child-bearing age. In a woman of fifty, Dr. Walter said that when it was possible he always removed fibroids by enucleation, or by a sort of Cesarean section. Although his experience in nearly every case was that the uterus was so bruised by this that it became a question whether it was worth while preserving, yet the operation should always be begun with the hope of saving it.

Dr. Croft having spoken, Dr. Fowell, in reply, held that the attainment of the tumour in the first case was so broad as to preclude any attempt at Cesarean section.

The President (Dr. J. E. Gemmell, Liverpool) read notes of a case of complete occlusion of the os uteri externus at full term. The patient was a primipara, who had seen when ther were twelve hours in labour. There had been some hemorrage, which proceeded from a vaginal laceration on the left; there was track of the amnion, but a cystic swelling bulged into the roof of the vagina, and in this the fetal head was felt. The patient was admitted into the lying-in hospital in a collapsed condition. On examination, a white swelling; the os was in the front of the swelling, and a crucial incision was made through it. The child was delivered with forceps, incision of the perineum being necessary. Subsequently the temperature went up, and local examination proving negative, antitetanus serum was given. After slow convalescence the patient left the hospital. It was pointed out that such an occlusion was not always the trivial matter it is generally regarded as being. Mattei, in a collection of cases, showed thirty-six operations out of forty-two cases, with three maternal deaths.

Dr. Lloyd Roberts mentioned two cases which had occurred in his experience, and the President replied.

Dr. E. Octavius Croft (Leeds) read a paper on three cases of urinary calculus in a female.

In the first case a stone weighing five grains was passed spontaneously per urethram. The second calculus weighed 232 grains, and was removed by vaginal cystotomy from a woman, aged 62. The same treatment resulted in the third case in the removal of a stone of 20 grains from the anterior vagina of a woman aged 20. Dr. Croft thought that in all three cases the calculi had their origin in the kidney, and he emphasised the necessity for removing stones of such a size by a vaginal incision in preference to draining them through the uterus, or performing a tedious lithotomy.

Dr. Grimsdale thought it better not to suture the vaginal incision; he preferred to place a tube in it and drain for a week before allowing spontaneous closure to take place. In a small vagina this was a great trouble.

Dr. W. WALTER agreed with Dr. Croft's remark as to the route adopted, and considered that even exploration of the bladder per urethram by means of the finger was unsafe.

The President and Dr. Lloyd Roberts having spoken, Dr. Croft replied.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.
MEETING HELD NOVEMBER 19TH, 1903.

The President, Mr. G. H. West Jones, in the Chair.

Dr. Arthur Hall showed the following cases:—(1) Old-standing lumps of face, treated by the light treatment for several weeks. (2) A late tuberculous syphilis. (3) Intra-thoracic new growth in a cuber, aged 53, with marked physical signs of obstruction of right bronchus and superior vena cava. (4) Thrombosis of portal vein in a blacksmith, aged 48; marked jaundice, previous health good, non-alcoholic. (5) Yellow jaundice (melanosis black) for two days, followed immediately by swelling of abdomen, vague history of pain in right side and yellow colour a year ago, not recognised as jaundice.

Dr. A. Cuff showed the following cases:—(1) Congenital absence of fibula. Before operation the child walked on the internal malleolus; arthrodesis of ankle-joint; there were also deficient development of the tibia and the ankle joint. (2) Necrosis of a large part of tibia; destruction of knee-joint; implantation of fibula into tibial head.

Dr. V. T. Cocking showed a man, aged 36, the subject of myositis ossificans. The disease, which was very advanced, commenced at the age of eight, and during the last few years the patient had been an inmate of many London and provincial hospitals. The case is reported by Dr. Rolleston in the Clinical Society's Transactions, vol. xxxiv., and in the Lancet, vol. ii., by Dr. Vaughan.

Dr. F. H. Waddy showed a case of acute and subacute rheumatism with serious cardiac lesions, and subluxation of the left clavicle.

Dr. G. Wilkinson showed a man, aged 37, from whom he had removed a retro-peritoneal lipoma, weighing 13 lb. 12 oz., which had been present for two and a half years, with attacks of vomiting and pain after taking food. When first seen the abdomen was found to be extremely distended, and absolutely flat in front, except in the epigastrium, where the note was tympanic. There was some resonance on the left flank behind. At the operation the whole of the intestines, with the exception of the descending colon, were found above the abdomen in the epigastrium. The fatty mass was separated from behind the intestines above, and turned forward. It was firmly fixed to the structures at the back of the abdomen by fibrous bands enclosing large vessels. These had been incised and ligatured in series. The growth had to be separated from the bladder, and the right ureter was found running through the mass, and had to be dissected out from about eight inches of its course. A prolongation of the tumour along the right spermatic cord, as aninguo-scrotal tumour, was removed. After removal of the lipoma a raw surface, about six inches square, bounded of perineum, was left on the posterior wall of the abdomen, chiefly on the right side. The mesentery fell down so as to cover this. A drainage-tube was put in through the right loin. The patient suffered from shock for twenty-four hours, after which he made a speedy and uneventful recovery. The tumour measured nineteen inches in length by twelve in breadth, and about six inches in thickness.

Dr. A. L. Husband read a paper on "Agoraphobia and Allied Conditions," which will be found on page 696.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD DECEMBER 2ND, 1903

MR. JOHN CHIENE, C.B., President, in the Chair.

DR. DAWSON TURNER showed a patient suffering from lupus erythematosus, treated with great benefit by the cathode breeze.

DR. W. ALLAN JAMIESON showed (1) a case of rodent ulcer of the foot, which had occupied about half of one side of the face; it was evacuated to the depth of an inch, and had been surrounded by infiltrated masses rising above the surface of the skin. It had already been removed thrice previously. The patient had had five minute exposures, the tube at a distance of six inches, four times weekly for several months, the treatment being interrupted on one occasion for three weeks on account of reaction. Complete cure had ensued. (2) A case of long standing chronic eczema of eighteen years' duration healed by pilocarpine. The patient was completely covered with it except on the soles, palms, nose, and chin; the skin was so thickened that he could not extend his limbs, and his sleep was disturbed by the irritation, so that the general health was much affected. He had been only been on pilocarpine for a year, and during the whole course of the disease; that was when business caused him to reside in London for a time, when the eczema was much better, but he suffered from asthma. Subcutaneous injections of pilocarpine from 1 to 10 grm. per day continued for two months had been followed by marked benefit.

MR. STRUTHERS and MR. MILES showed four patients illustrating the results of Bennett's fracture.

DR. GEO. A. GIBSON showed an early case of acromegaly in a youth, at 18, manifesting the enlargement of the hands and feet and lower part of the face, along with bitemporal hemianopsia.

MR. WALLACE showed a series of histological sections and specimens from the case of congenital hemihypertrophy of the tongue exhibited at the previous meeting.

DR. BUCHAN showed microscopic preparations from a case of asthma.

MR. MILES and MR. STRUTHERS showed a series of metacarpal bones of thumb, illustrating Bennett's fracture, with radiograms.

DR. CHALMERS WATSON read a paper on:

SOME NEW OBSERVATIONS ON THE PATHOGENESIS OF GOUT.

The communication was chiefly of the nature of a demonstration, the tissues shown being taken from a young adult fowl which had succumbed, after a short period of illness, to naturally acquired gout. Such cases were very rare in the records of the disease, and, so far as the author was aware, none had been submitted to so complete a histological examination as the present case. The naked-eye appearance of the tissues were: alterations of the synovia to a cream-like fluid, which gave the mucrode reaction, deposit of urate in combination on some extra-articular tissues round the smaller joints, recent periartitis, widespread thrombosis, and areas of "necrosis" in the kidneys. Microscopic examination showed other changes—e.g., (1) intestinal cataract, notably in the ileum, duodenum, and large intestine; (2) blockage of the pancreatic duct by catarhal exudate; (3) pronounced congestion of liver, spleen and kidneys; (4) deposit of urate of soda in a lymphatic gland; (5) the collecting tubules of the kidneys distended with granular leukocytes. These appearances were regarded as characteristic of a bacterial infection; and the author emphasized the importance of further attention being directed to comparative pathology, as the means most likely to advance our knowledge of the disease. It was specially important to obtain cases like the one recorded, but at an earlier period, so as to admit of an adequate bacteriological examination of the tissues. Attention was drawn to the blood changes, as emphasizing the importance of having regard to the changes in the blood in acute gout in man, which had already been described by the author and corroborated by Bain. The changes observed in the intestines recall, and give a new importance to, the old-time theory of gout, as an intestinal auto-intoxication or infection, which was revived by the author in 1901. The appearances seen in the pancreatic duct were described as possibly having some significance in relation to the familiar clinical feature of the disease—gouty gloscosuria.

DR. GULLAND was unable to accept Dr. Watson's interpretation of the case; he regarded it simply as a terminal bacterial invasion in a probably gouty animal.

DR. DAWSON TURNER gave a short communication on "Radium," describing the history of its discovery and isolation from pitchblende. Radiations employed in practical medicine might be classified in two groups:—(1) Radiant heat; (2) light; (3) ultra-violet rays; (4) Röntgen rays; and (5) radium emanations.
Some of the physical properties of radium were described, and its bactericidal action discussed. Specimens were shown and its property of discharging the electroscope demonstrated.

Dr. Claude Ker, superintendent of the fever hospital, read a paper on—

THE OPEN-AIR TREATMENT OF BRONCHO-PNEUMONIA COMPLICATING WHOOPING-COUGH.

The great seriousness of whooping-cough, at least among the poorer classes, was evidenced by the fact that its death-rate up to the fifth year was not less than 4·6 per mille, nearly one-third of the total 15·7 per mille death-rate of the community. The great mortality was principally due to bronchitis and broncho-pneumonia, the other conditions chiefly responsible being tubercle and meningitis. The hospital death-rate was very high, chiefly because they only admitted the worst cases of whooping-cough, and because they took in a relatively large proportion of cases from the children’s hospital and from the children’s shelter, and these cases were complicated by pre-existing diseases. For the eight years preceding 1900 his mortality had been 18·11 per cent.; in Glasgow it was 18·3 per cent., the chief causes of death being broncho-pneumonia and convulsions, and the practical difficulties which confronted them in treating the children were to procure sleep, which was interrupted by the cough, and to support the strength, which was interfered with by the recurrent vomiting. He had tried all the drugs that had been recommended for whooping-cough, and all modes of internal and external manipulation, except for bellying the upper lip, which he thought sometimes lessened the frequency of the paroxysms, he had seen little advantage from any. In broncho-pneumonia he had tried all the ordinary lines of treatment—politicizing, ice-baths, &c., and in all the mortality had been about equal: two-thirds of the cases died—71 per cent., as compared with 76 per cent. in Glasgow. He had been led to try treating these cases outside by the frequency with which they ultimately became tuberculous, and also because of the frequency with which pneumonia spread in the wards. The cots were placed outside for the greater part of the day, there being no contra-indication except frequent convulsions and laryngitis. The open-air treatment had no effect on the frequency of the paroxysms of cough; it had little effect on the temperature; the appetite became voracious; sleep and general health was greatly improved. Another indirect advantage was that it allowed the wards, in which whooping-cough were particularly liable to become offensive, to be thoroughly aired daily. No bad results whatever were noticed, but the mortality rate fell very markedly. At first all cases were treated in doors; then the fatalities were 71 per cent.; then half the patients were treated out of doors; the mortality fell to 54·5 per cent. When all the patients were treated outside it fell to 26 per cent. In winter, when the children were treated under cover, in wards converted to sanatoria, it rose to 27 per cent. Since he had begun to treat his cases of whooping-cough out of doors broncho-pneumonia contracted in hospital had become extinct.

Dr. Carmichael congratulated Dr. Ker, and generally confirmed his views. He referred to the enormous death-rate from whooping-cough, and thought it required more attention from the public health authorities.

Dr. Caverhill spoke of the advantages to all infectious cases gained by treatment out-of-doors.

Dr. Littlejohn thought that since the chief cause of death in whooping-cough was broncho-pneumonia, and since that was due to a second infection, it was most important to isolate broncho-pneumonia as soon as it arose.

Complicating Whooping-Cough.

In which they stated that, though, since the fracture was first described by Bennett in 1831, records of only some nine or ten cases appeared in the literature, such injury must be commoner than these figures would represent, for they themselves had met with about nineteen cases during the past few years. The fracture is always caused in the same way, by direct violence applied to the thumb while it is fully extended, and passes obliquely through the base of the metacarpal, detaching the articular facet with that piece of bone forming its base. The injury was formerly described as "stave of the thumb," or "partial luxation of the metacarpal of the thumb backwards." Its clinical signs were limitation of movement of the thumb, interfering with the grasp, and some slight prominence to the radial side. The fracture consisted in the application of a splint which was firmly fixed to the thumb by pieces of strapping, extension was then made, and the presence of the splint strapped to the wrist so as to maintain the extension. Radiograms of recent cases, as well as preparations showing the fracture, were described.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held November 20th, 1903.

Dr. H. R. Hutton (Manchester) in the Chair.

Dr. James Taylor showed an anomalous case of diplegia. A child, aged 4, soon after an operation for an abscess of the right side of the neck, became altered mentally and lost the power of walking. Additional symptoms followed, viz., some depression of concentration, and some regurgitation of fluids through the nose, squinting, absence of knee-jerks, and marked inco-ordination. Most of the symptoms had passed off under treatment, but the degree of intelligence was not yet quite up to the normal standard. The diagnosis made at first was one of diptheritic paralysis, although there was no history of sore throat. He was now inclined to look on the condition as some other form of toxemia, which had led to alterations in the cerebral cortex, and possibly also in the spinal cord.

Dr. Shuttleworth had never seen mental deterioration follow immediately on diptheria, but he recalled one case in which an attack of diptheritic paralysis was said to be the precursor of mental impairment. In the present case he thought that some previous mental weakness had been aggravated by the acute illness.

Dr. Fletcher had had a case of similar nodules in an adult, which was completely cured by the internal administration of iodiform.

Dr. Cauntley recalled a case in a baby, aged 10 months, who died ten weeks later from tuberculous meningitis. At the autopsy four caseating nodules were found in the brain, also caseous glands in the mesentery and mediastinum, and miliary tuberculosis of the lungs.

Mr. Lockhart Mummy suggested the excision of one of the nodules to determine whether it was a pure tuberculous affection or a mixed one.

Mr. Fritchard had seen a case in a lady which had lasted for two years, and was finally cured by arsenic.

Dr. G. A. Sutherland showed twin sisters, aged 5, who were the subjects of idiocy.

Dr. Leonard Guthrie remarked on the strong family likeness which such cases showed, although the particular defects were not the same. He thought that in many cases there was defective visual memory, because if the child looked away from the speaking mouth it forgot how to form the words. The prognosis might appear to be hopeful, but he found a tendency...
The patient died at the age of fourteen weeks, and the pylorus presented the usual characteristics, but both small and large intestines contained a considerable quantity of normal feces. While under observation, he had gained thirteen ounces in weight during one period of two weeks, and six ounces during another period of one week. During life peristalsis was noted on one occasion only, the pylorus being relaxed. In the stomach was moderately dilated, and vomiting was present, but was not characteristic. There was not marked constipation, and even eight days before death a large, almost normal, stool was passed. Dr. Cautley thought that the stomach was more ready to vomit in one of these cases, but not entirely, in order to make the pylorus more easily accessible to the instrument used in examining it; and in order to make the patient more easily treated. He thought that the absence of characteristic vomiting in this instance might be urged as an argument against the view that the hypertrophy was due to spasm.

Mr. Clinton Dent related two cases of the same disease successfully treated by pyloroplasty.

Dr. Alexander Morison showed the stomach of a child which hypertrophy had been diagnosed, and the patient had been admitted for operation. While under observation the patient vomited very little, and only occasionally exhibited gastric peristalsis. Operation was deferred, and the patient was discharged, but returned in a collapsed condition, with a temperature of 90° F., and died soon afterwards. At the necropsy the pylorus was found to be large, long and hard, the stomach inflamed with air, and only required the cardiac end to be ligatured to remain inflated, as the pyloric end was impervious. Dr. Morison dwelt on the necessity for operation in such cases, even when the condition was merely suspected to exist.

Mr. Howard Evans said that with the congenital hypertrophy there might be a marked degree of spasm, which, when aggravated by irritation, as from ill-digested food, would lead to dilatation. He narrated a case in which the patient, in which the pylorus was found to be large, long and hard, the stomach inflamed with air, and only required the cardiac end to be ligatured to remain inflated, as the pyloric end was impervious. Dr. Morison dwelt on the necessity for operation in such cases, even when the condition was merely suspected to exist.

Mr. Turtle had seen five cases operated on by dilatation of the pylorus during the last twelve months, all of whom had recovered. Three of the cases returned later with diarrhea of a very troublesome nature. He suggested that the pylorus was under-stretched, so that it was unable to retain the food in the stomach sufficiently long for digestion.

Ulster Medical Society.

The second meeting of the session of this Society was held in the Medical Institute, Belfast, on Thursday evening, December 3rd, Professor Byers occupying the Chair in the absence of the President.

The following gentlemen were elected Fellows of the Society:—Dr. A. E. Knight Donaghadhe; Dr. J. C. Woodside, Ballycastle; Dr. James Fulton, Belfast; and the following elected members:—Dr. Wm. Hanna and Dr. John Armstrong, both of Belfast.

Mr. Fulerton, F.R.C.S., read notes and showed sketch-diagrams of two cases.—(a) Case of impaction of a coin for seven months in the oesophagus of a child, successfully treated by oesophagotomy. (b) Transverse ulceration, with over-riding of the upper end of shaft of humerus, treated by operation.

Mr. Robert Campbell, F.R.C.S.,Eng., read a paper on the Radical Cure of Hernia in Infants and Young Children, illustrated by a sketch of his paper. Mr. Campbell said that the usual steel and rubber truss was not so satisfactory as it first seemed. To be successful with it both care and money were needed, for the child must be carefully watched, and a new truss got as often as required. He considered it wiser to operate on all hernias in children, with the possible exception of small easily reducible
hernias in the children of well-to-do people. In favour of operation was the fact that it meant about 14 days' treatment, as against three years required for treatment by trusses. The risk of death from operation was not greater than the risk of death from strangulation during treatment by truss. His cases included 100 boys and 5 girls, the two youngest being 14 and 21 days. They were all inguinal hernias. In none was there any tendency towards gangrene, though the formation of haematoma was common. Mr. Campbell described the technique of the operation in detail, laying special stress on the use of carefully prepared formalin catgut, and on bandaging the scrotum. In his 114 cases he had never known suppuration in the wound occurring more than once, and twice the formation of blood clot in the wound necessitated the opening of the wound for its removal. As regarded the results, he had watched the majority of his cases for six months, and only in one was there a slight tendency towards return. He concluded by reiterating the opinion that the use of the truss should be the exception and not the rule.

Dr. Walton Brown said that seventeen or eighteen years ago in that Society, he had urged the necessity of bandaging the scrotum.

Dr. Kevin remarked on the apparent heredity of hernia; he had seen three brothers and a half-brother by the mother of each affected.

Dr. O'Neil did not agree with Mr. Campbell on the use of the truss. In his experience three-fourths of the cases could be cured in one year by the use of a properly fitting truss. He believed 30 per cent. of cases were hereditary.

Dr. McHarry said that as a general practitioner he saw many cases of hernia in the poorer classes, and found it impossible to get them to get them to wear a truss properly. Dr. Fielden, Mr. Fullerton, and Dr. Dempsey having spoken, Mr. Campbell replied.

THE GENERAL MEDICAL COUNCIL OF EDUCATION AND REGISTRATION.

SEVENTY-EIGHTH SESSION, 1903.

FIFTH DAY.—SATURDAY, NOVEMBER 28TH, 1903.

Sir William Turner, K.C.B., President, in the Chair.

Communications were read from the Royal College of Physicians of London and the Royal College of Surgeons of England acknowledging the receipt of certain reports from the Education and Examination Committees of the Council, in which the following reply was made:

"The Royal Colleges thank the General Medical Council for the expression of their opinion respecting the courses of study and the examinations in Chemistry, Physics, and Biology. These opinions shall receive the respectful attention of the two Royal Colleges. The Royal Colleges, however, regret that they are unable to accept the invitation of the President of the General Medical Council to appoint representatives to meet the representatives of the General Medical Council in regard to the questions of Medical Education and Examination relating to the subjects above mentioned, that have been raised in the Reports of the Education and Examination Committees of the General Medical Council."

These were received and entered upon the Minutes.

Sir Victor Horsley then moved—

"That the Council do represent to His Majesty's most Honourable Privy Council that the courses of study and examination in Chemistry, Physics, and Biology, to be gone through in order to obtain qualifications for registration from the Examining Board in England, of the Royal College of Physicians of London and the Royal College of Surgeons of England, are not such as to secure the possession by persons obtaining such qualification of the requisite knowledge and skill for the efficient practice of their profession."

He urged that it would be to the interests of the whole of the medical profession to expedite a matter that had been going on for the last five years. By the refusal of the Royal Colleges to meet the representatives of the Council he contended that they were taking up a somewhat contumacious position, and that it was only by referring the subject to the central Government that the case of those who really were the supreme authority.

Dr. Pye-Smith objected to the word "contumacious" as employed by the speaker.

Sir Victor Horsley replied that he thought the profession would understand the meaning of the term. He considered that the Council had received a direct challenge from the two Royal Colleges.

Dr. Mackay, in seconding the motion, said that the reply of the Royal Colleges, though courteous, he felt it to be the duty of the Council, if it was not satisfied that the examining bodies in question required an adequate course of study, to represent the same to the Privy Council, especially as they implied that the Council was not entitled to interfere in such matters.

Mr. Bryant desired to point out that the question of authority was not the main point at issue. He stated that the Royal Colleges distinctly said that the opinion of the Council was receiving the fullest and closest consideration, and that it would not be answered.

Dr. Norman Moore affirmed that the Royal College of Physicians possessed the greatest respect for the opinion of the Council. Referring to the use of the word "contumacious," he pointed out that the legal use of the term signified "willful disobedience of a court." But were the orders? There had been no edict, therefore the word was wholly inapplicable. He stated that authority was given to the College by its charter to determine the course of study for its students, which was confirmed by an Act of Parliament.

Mr. George Brown asked if the Medical Act of 1858 in any way repealed the Act referred to by Dr. Norman Moore.

Dr. Norman Moore, having replied in the negative, said he wished to convey that his College was considering the Report of the Council most fully.

Sir Christopher Nixon said he was in favour of placing the studies of Chemistry, Physics and Biology outside the medical curriculum. He thought it was time that the Council should determine whether it was within its rights in interfering in these matters. He agreed that it had done all in its power to improve the status of the profession.

Dr. Bruce then moved the following amendment—

"(1) That the Council acknowledges the communications set out in the Minutes of to-day from the Royal College of Physicians of London, of November 19th, and the Royal College of Surgeons of England, of November 20th. (2) That the Council is pleased to note that the opinions of the Council respecting courses of study and examination in Physics, Chemistry, and Biology are to receive the respectful attention of the two Royal Colleges. (3) That in view of the re-consideration of the courses of study and examination by the Royal Colleges, the Council resolves to defer taking any further action until the examination had been again inspected under the new regulations."

He asked how it would be if the Council failed to establish its position, and he foresaw several stumbling-blocks in the carrying out of Sir Victor Horsley's motion, to which he could not agree.

Dr. Pye-Smith, in seconding the amendment, said that he could only say that there were already certain changes which had been made by the Royal Colleges in the curriculum, but he was not in a position to describe their exact nature.

Sir Victor Horsley said he would like to see documentary evidence of such changes.

Dr. Norman Moore said that these considerations required a large amount of time and that a great deal of consultation between the two bodies was necessary. Certain principles of change were in actual progress, but as they had not yet taken a final shape, he was unable to state what these were more fully.

Dr. Pye-Smith said the profession did not desire any cause of peace. He thought that the question of jurisdiction was rather one of difference of opinion which might
easily be overcome. He referred to the excellent laboratories present in many of our public schools. He considered that all examinations had both good and bad features, and that the College of Physicians was fully aware that their examination was insufficient. He regretted himself that the Colleges had refused a conference, but the bringing of such charges was apt to cast a doubt of independence. He strongly deprecated any appeal to the Privy Council. The influence of the Council could not but be felt by all the licensing bodies, but if it were to prove its authority before a lay tribunal he feared the result would be disastrous to the public and cause irretrievable mischief.

Dr. Windle read extracts from the medical journals which gave evidence that the Royal Colleges were amending their regulations.

Mr. George Brown maintained that the General Medical Council was fully competent to supervise the course of study prescribed by the Colleges, and he did not see how it was possible to ensure that these bodies would carry out the recommendations of the Council unless they were reported.

Sir Charles Ball thought that the motion brought forward by Sir Victor Horsley would bring matters to a climax.

Dr. Little pointed out that if they went to the Privy Council they would be obliged to bring specific charges against the Royal Colleges. He thought that the best way of settling the matter would be by negotiation.

Dr. McVail thought that in the face of all this evidence it would be to the interest of the cause that Sir Victor Horsley had at heart if he were to withdraw his motion.

Sir Victor Horsley replied that he could not be satisfied with only a general explanation. He denied that the Council possessed that influence which Dr. Pye-Smith had attributed to it. He demanded that the Council should be satisfied that it would be allowed to exercise its powers of supervision. He could not see his way to withdraw his motion.

Mr. Finlay then put the amendment to the vote, which was carried by a majority of four, and, therefore, became a substantive motion. For the amendment were Dr. MacAlister, Mr. Bryant, Dr. Norman Moore, Mr. Tomes, Dr. Pye-Smith, Sir John Moore, Mr. Young, Dr. MacLachlan, Dr. Anderson, Dr. Lindsay Steven, Sir John Williams, Bart., Sir George Philipson, Dr. Windle, Dr. Finlay, Dr. Bruce, Dr. Little, and Sir Hugh Beevor, Bart. Against were Dr. McVail, Sir Patrick Heron Wylie, Sir Charles Ball, Dr. MacKay, Mr. Brown, Mr. Tichborne, Mr. Jackson, Sir Christopher Nixon, Dr. Bennett, Sir Victor Horsley, Sir William Thompson, and Sir John Tuke.

The motion was proposed as an amendment, and Sir John Tuke seconded, that the consideration of this motion be postponed. This was carried by a majority of one.

The Council then adjourned.

SIXTH DAY.—MONDAY, NOVEMBER 30TH, 1903.

A Report was read from the Examination Committee of the Final Examination of the English Joint Board, which was received and entered upon the Minutes. Its adoption was then moved by Mr. R. Bryant.

Dr. Finlay, in seconding, wished to dissociate himself from one thing mentioned, and he called attention to the diversity in the regulations of the examining bodies by which candidates could be allowed to take one subject at a time at certain boards while at others they could not do so.

Dr. Payne thought that there should be greater uniformity with regard to requiring written reports upon clinical cases at these examinations.

Mr. George Brown considered that there existed a distinct lapsus in the remarks of the bodies inspected, inasmuch as no reference was made to the Inspectors’ statement that certain portions of the examination were insufficient. He would, therefore, move as an amendment, which was seconded by Sir Victor Horsley, that the further consideration of the Report should be postponed until after the remarks of the Court of Examiners had been forwarded to the Edinburgh Council.

Dr. Lindsay Steven said that written reports of cases were required in the final examinations at Glasgow, and Sir John Tuke affirmed the same thing with regard to Edinburgh.

Dr. Norman Moore claimed that the Colleges had a right to a definite expression of opinion on the part of the Council, and that it would be discourteous not to inform them. In this view he was supported by Dr. MacAlister, Dr. Mackay, Sir Christopher Nixon, and Dr. Little.

Dr. Bruce having pointed out that a postponement of the question did not imply discourtesy, the amendment was put to the Council, and lost. The original motion was then put and carried.

The reports upon the inspection of the Final Examinations of the Irish Joint Board, the Society of Apothecaries of London, and the Apothecaries’ Hall, Dublin, were next read, received, and adopted.

The Council then retired in camera, and on the re-admission of strangers the President announced that the Council had directed the Registrar to restore to the Medical Register the name and qualifications of Charles Augustus Bynoe.

The President also stated that he had been authorised to communicate with the Local Government Board with regard to dental certification.

A report was next read upon the inspection of certain preliminary examinations, and as regards that of the Educational Institute of Scotland the improvements already effected, or about to be introduced, were considered as so satisfactory by the Education Committee that it was anticipated that during the next year it would have attained in every respect the standard desired by the Council.

With regard to the use of unprepared books in Latin and Greek in these examinations, Sir Christopher Nixon said he thought it was impossible to make uniform regulations, since at the matriculation examination of the Royal University of Ireland, which was recognised by the Council, unprepared books were not employed.

The report was then adopted.

Sir John Tuke then read a communication from the Secretary of the Apothecaries’ Hall, Dublin, stating that that body intended to resume its preliminary examination in Arts, which, in deference to the express wish of the Council, they had for many years discontinued. In view of the grave educational issues involved, the Committee recommended that the Council should not approve of the step contemplated by the Apothecaries’ Hall, Dublin.

Mr. Tichborne explained that the Apothecaries’ Hall, of Dublin, had no desire to go against the wishes of the Council in this matter, but they were forced into it because the Conjoint Bodies had instituted a similar plan.

Dr. MacAlister said that this body, by its constitution, was not qualified to hold an examination of this nature which could be received by the Council.

Sir John Moore expressed his surprise at the statement that the Apothecaries’ Hall, Dublin, was on the same footing with the Royal Colleges in respect to this matter. He saw no raison d’etre whatever for holding this examination.

Sir Christopher Nixon feared that it might be an instance of a policy of retaliation.

The report and the recommendations of the Committee were adopted.

A report was then read from the Pharmacopoeia Committee in which it was shown that the total number of copies of the Pharmacopoeia disposed of were 34,591, and of the Addendum, 664. The final instalments of the investigation on the solubilities of drugs, conducted in the research laboratories of the Pharmaceutical Society of Great Britain by Professor Greenhill, had been forwarded by the Council of that Society to the Committee. Professor Dunstan, of the Imperial Institute, had made substantial progress with the examination, begun last year, of the pharmacopoeial
tests for arsenic. In view of the laborious character of the inquiry, the Committee proposed that a second and final grant of 50 shillings should be made to Professor Dunstan to enable him to complete the work and prepare it for the next issue of the Pharmacopoeia. This report was received and approved.

Sir Douglas Muxlow was appointed a member of the Pharmacopoeia Committee in place of Dr. Atthill.

The Public Health Committee reported that they had considered a recommendation made to the Secretary of State for War by the Advisory Board for Army Medical Services that certificates issued by the sanitary officer of the Bombay command might be recognised by the Council as certificates for the D.P.H. examination under Rule 3 (e) of its Rules and Regulations for Diplomas in Public Health. The sanitary officer in question had his headquarters at Poona, a city of 120,000 inhabitants. Taking into account the precedent of Gibraltar, the Committee recommended that the Bombay command should be added to the list of recognised military districts.

Sir John Tuke objected to the consideration of such an important matter so late in the day. Dr. Windle therefore moved, and Sir Victor Horsley seconded, that it should be postponed, which motion was rejected by 13 votes to 10.

Dr. Macalister pointed out that the recommendation should distinctly state that it was desirable that the sanitary officer in Bombay should be registered as holding the D.P.H., that he should give his whole time to the work, and that the certificates should state that the candidates had had sufficient opportunities of acquiring knowledge of the working of the Public Health laws in relation to a civil population of at least 30,000.

With this addition, the original motion was carried.

On the motion of Dr. Macalister, a reply was directed to be sent to the Apothecaries’ Hall, Dublin, calling the attention of that body to the fact that the terms of the Act of 1886 required that the travelling expenses of the examiners in Surgery should be paid by the Apothecaries’ Hall, Dublin.

The report from the Students’ Registration Committee was next adopted, and the thanks of the Council were voted to Dr. Windle and Professor J. Campbell Brown for their visitation and reports upon the first medical examinations of the Licensing Corporations of the United Kingdom.

With a vote of thanks to the President for his conduct of the proceedings, the Session was brought to a close.

France.

PARIS, December 8th, 1903.

THE SERUM OF MARMORECK.

It will be remembered that some time ago the public Press revealed the existence of a certain amount of dissension existing between M. Marmoreck and his colleagues at the Pasteur Institute. Marmoreck, believing that he had discovered the serum of tuberculosis, announced his decision of communicating the results of his experiments to the Académie de Médecine. His colleagues, mindful of the discomfiture of the tuberculin of Koch, refused to lend their authority to the intended declaration, which they considered as premature. Relations were thus strained, and the resignation of M. Marmoreck was hinted at, but the difference was more or less arranged and M. Marmoreck remains at the Institute.

On the other hand, the séance of the Académie de Médecine was almost wholly taken up this week by reports from several members on the supposed value of the serum in the treatment of tuberculosis.

M. Dieulafoy said that during the months of August, September, and October of last year seven tuberculosis patients in his wards were treated by the serum of Marmoreck. Four of these were in different stages of pulmonary consumption, two suffered from tuberculous laryngitis, while one was affected with pleurisy. M. Marmoreck himself practised the injections, and as frequently as he desired. The quantity of serum injected each time was from 5 to 10 grammes. The result of the treatment was not favourable to the patients. The fever was not modified, the expectoration had considerably increased and the patients continued to get thinner in spite of good feeding. For these different reasons the failure of the treatment being proven, M. Dieulafoy felt obliged to ask M. Marmoreck to cease his injections.

M. Monod said that M. Marmoreck had tried his treatment on several of his patients suffering from local tuberculosis. They all somewhat improved under the treatment and the speaker thought that on the whole the results were rather encouraging.

M. Le Dantu had had treated by the Marmoreck serum a patient suffering from tuberculosis of the head of the tibia, while the lungs were slightly affected. Fifteen injections were made, but there being no result they were stopped. The man subsequently succumbed to the progress of the lung lesions.

M. Halloper had tried the treatment on seven of his patients suffering from various forms of cutaneous tuberculosis. Not only did it have no curative effect, but many of the patients became worse under its influence.

TREATMENT OF CHOREA.

The arsenical treatment of chorea has been from all times the recognised procedure for this curious affection, but all authors insisted on the necessity of saturating the organism with arsenic, a fact entailing not infrequently considerable gastric disturbance. According to Professor A. Gautier the same end can be obtained without risk by injections of cacodylate of soda, the organic preparation of arsenic, inoffensive, non-irritant, and non-toxic. Professor Grasset, of Montpellier, who has also adopted this preparation in the treatment of St. Vitus’ dance, considers that equally good results can be obtained by giving it by the mouth or by the stomach. Dr. Garand, of St. Etienne, has published three successful cases of children cured by injections into the rectum of 14 grains of cacodylate of soda. Intolerance and disagreeable taste were due to impurity of the drug.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 8th, 1903.

At the Society für innere Medizin, Hr. Lassar brought forward the subject of TUBERCULOSIS OF THE TESTICLE TREATED BY HETOL, and showed a case. The patient was a strongly-buit and healthy-looking man, with a tuberculosis family history, but who had always enjoyed good health himself. A long time ago he contracted gonorrhoea, which was complicated by an affection of the left epididymis. Possibly this illness in some way allowed the entrance of tuberculous infection, or the immediate cause might be an injury. Two years and a half ago he fell the distance of three feet and bruised the right testicle in the fall. For years this remained without material improvement, and led to tuberculosis of the organ, the left also becoming infected. Fistula formed, and the medical attendant proposed double castration. When the speaker first saw the patient, he did not at once support this advice, but cast about for other means of treatment. He first recommended that by hetol, and
The independence of glycocalic fermentation had been ascertained by Lépine, Jacoby, and himself. He personally found that glycocalic was a fermentative process, and he had isolated the ferment. He found the ferment also in all the organs examined—liver, spleen, and pancreas. He examined the products of glycocalic also, and determined the formation of carbonic acid. He could not find alcohol with certainty, he therefore concluded that glycocalic was an independent process, caused by a ferment that converted the sugar into carbonic acid and water, and that it was not consumed in the form of an alcoholic fermentation.

Glycoalysis in other organs had recently been confirmed by Feinschmidt, Hirsch, and others. All these authors found a glycocalic ferment in the liver, the muscles, in the kidneys, and in the blood, and Nadine Sieber especially remarked that the glycocalic ferment she had obtained from fibrin did not convert salicyl-aldehyde into salicylic acid, and that it was different from an ordinary oxidizing ferment.

More recently, Stocklasa and Czerny had believed glycocalysis to be an alcoholic fermentation. Considering the great significance of this view for the whole subject of alcohol, the speaker and Feinschmidt had gone over the ground again. They had found that although in most experiments alcohol was formed along with carbonic acid, the quantity was but small, so that one could not speak of an alcoholic fermentation. Seeing almost all the organs contained the glycocalic ferment, it was doubtful whether the part played by the pancreas in diabetes depended on the glycocalic ferment contained in it. Regarding this point, the investigations of Cohnheim and Rachel Hirsch were of special importance. They found that the glycoalysis of the liver and of muscle was rendered considerably more active by addition of pancreas, and concluded from this that the rôle played by the pancreas depended on its secretion of a substance that, like a foreign body, attacked the glycocalic ferment to the sugar molecules, or, like enterokynosis upon trypsine, thus rendering the glycocalic ferment active. This was not quite his own opinion or Brauneit's, who found a very active ferment in the white blood corpuscles that acted more rapidly and more glycocalically than the liver and muscle ferment: activated by pancreas. In three and a half hours they saw 33 per cent. of the sugar disappear. One might draw the conclusion from this that glycoalysis took place in the blood and not in the organs. This would not be correct. No glycoalysis could take place in the blood, as blood serum contained an anti-glycoalic body. The leucocytes were only the carriers of the ferment, which bore to the organ cells, especially to the muscles.

This view being correct, if pancreatic diabetes depended on the absence of the glycocalic ferment and the activating body, then the glycocalic function of the tissues must suffer in the disease. The speaker related three cases of severe diabetes in which this was the case. In conclusion, he discussed the treatment of diabetes with glycocalic ferment. Attempts hitherto made had not yielded results, but the result could, indeed, be achieved until by isolation of the ferment or of the activating substance the material could be produced in large quantities. This problem should speedily be solved. But it was further to be weighed whether the treatment of diabetes would be perfected by this. Possibly the other disturbances of tissue change that appeared with diminished combustion of sugar in pancreatic diabetes did not altogether depend on diminished glycoalysis, but were caused by other bodies that could not perform their functions owing to the disease in the pancreas.

Präulein Hirsch said she had not found a glycocalic function of the pancreas, but she had of the liver.

**Austria.**

**[FROM OUR OWN CORRESPONDENT.]**

**VIENNA, December 4th, 1908.**

**DIAGNOSTIC ERRORS ACCORDING TO MODERN OPINION.** At a meeting of the Doktorkollegium, Hovorka drew attention to the injury of so many special divisions of the body that were now treated with harm to the patient under the ægis of a specialist. He admitted the potency of special knowledge after one had a thorough comprehension of the entire organism, but special knowledge without this was positively injurious. He contended that the practitioner was the best specialist, and one whose diagnosis was the most trustworthy. A few examples would illustrate his contention. Torticollis may or may not be a local disease, but most frequently it was constitutional, probably having a rheumatic basis. It might also be rhachitic with cervico-dorsal scoliosis, or simply due to habitual inclination of the head, a cicatrice, or rupture of the spinal membrane. In this connection he reminded practitioners of Brissaud's "mental" form of torticollis, which should be borne in mind when making a differential diagnosis. He warned the practitioner against the negligence of diagnosing scoliosis at the very earliest moment when treatment can be effectively applied. Spondylitis, lumbago, &c., are never difficult to diagnose. At this point he showed two cases suffering from epileptic fits, which were diagnosed as due to calculi in the bladder. Cystotomy was performed in both cases with no relief—the cause in both cases was due to spondylitis. Errors often occur with rhachitic kyphosis and habitual scoliosis.

He also related a case of mistaken diagnosis of scoliosis for floating kidney; another of ischias scolitica for simulation, as well as others in coxa vara.

**PERFORATION OF ALVEOLI.**

Swoboda showed an infant to the members of the Gesellschaft der Aerzte with perforation of the bony structure of the alveoli in an hereditary syphilitic family. The child was eight months old; there was no real complaint, without any symptom, lesion or defect about the mouth such as difficulty of swallowing, purulent matter from the nose, &c. Inunctions of mercury speedily closed the fissure, which was 4 millimetres wide—0.145 inch. Swoboda presumed that this hereditary lesion was often present, but owing to its non-interference with the physiological action of the organ, passed over undetected.

Neurath related a similar perforation that he had met with in a case of syphilis of the larynx.

**URANOPLASTIC OPERATIONS.**

Esselberg raised the question of results obtained
from uranoplastick, or hiatus palati, operations. He maintains that the functional results from cleft palate, notwithstanding the perfection attained in the technique of the operation, is very small. The most important defect, in his opinion, is the neglect of these cases after operation, which cannot be said to be complete until the function be restored, and cannot be recovered from without careful systematic training. At this time, four cases on which he had operated eleven, twelve, thirteen, and fourteen years ago. Two of these were complete operations, and two were failures from a vocal point of view, as the whole of their conversation was passed through the nose. With proper training he is convinced this defect in the results of the operation could be overcome.

HEMIPLEGIA AND MECHANOTHERAPY.

Roth brought before the members of the Society a patient who had had an apoplectic fit four months ago, which paralysed the seventh facial, eleventh recurrent and twelfth hypoglossal, as well as the whole of the nerves of the left side of the body and left leg. In order to prevent contractions, Roth commenced eight days after the onset a passive movement several times a day. Several hours a day and during the whole night an instrument was applied to assist the patient's movement. By this early form of treatment a good result is attained, as the patient can now move about with comparative ease and steadiness. He thinks this early application of the mechanotherapy would remedy many of the deformities that follow hemiplegia. 

SPONDYLITIS SYLVHITICA.

Neumann reported the history of a case of spondylitis Sylvhithica to the Society. 

The patient was a young commissionaire, aged 35, who acquired spondylitis seven years ago, since which time he has been under personal supervision. The whole course might be described as "torpid," in spite of repeated heroic treatment. Immediately after a course the symptoms would abate in one place and recur with greater intensity in another, such as palate, pharynx, larynx, &c. Three years before his death the sound could be passed into a crater-like ulcer in the back of the pharynx till it came against the demended vertebra. Accompanied by stiffness of the neck and immobility of the head, pain over the region of the occiput and the spinous process of the neck, which extended far down the column.

In the last month of his illness the temperature began to rise gradually with the development of a purulent phlegmonous process indicating a mixed infection, which, commencing in the neck, passed along the connective tissue in the pleural cavity and finally caused death.

The post-mortem was conducted by Stoerk, who recorded perfect destruction between the third and fourth cervical vertebrae, with dislocation of the adjoining structure.

The resulting discharge was found to be loaded with a mixture of organisms which had probably obtained admission during the previous three years' destructive discharges from the osseous vertebrae.

Neumann remarked that this was an unusual case, though not unknown, as there were now thirty-six such cases on record, where the sphylicitic destruction attacked the bony structure of the neck and localised itself in the vertebrae, producing spondylitis. Withstanding the frequency of spondylitis in the soft tissues of the throat, this erratic form is comparatively rare, and must be assumed to be connected with tubercle, although not clearly demonstrated.
and dressed with a dry pad of gauze. Mr. Grimsdale said that the choice of operation in these cases varied with the fact of the condition being unilateral or bilateral. The lid could be raised either by the frontalis or by a slip from the superior rectus as after the manner of Motais. The latter method had the advantage that the movements of the lid and globe were co-ordinated almost as in the normal condition. When the frontalis was used, as in the present operation, there was no unnecessary agreement between the movements of the lid and eye. A Motais' operation was not admissible, however, in unilateral cases since the additional work put on the superior rectus prevented it raising the globe normally with its normal fellow and therefore very troublesome diplopia followed in the majority of instances. He was therefore bound to make use of the frontalis. Several operations, he pointed out, were possible, either employing an artificial tendon as was done by Mules, of Manchester, who attached the tarsal cartilage to the frontalis by means of a thin gold wire, or the use of a skin flap sewn directly to the frontalis underneath the eyebrow, as was done by Panas, of Paris. The former operation—that of Mules—he said, was simple and generally successful, but the gold wire occasionally broke on introduction or slipped after the wound was healed. Panas' operation on the other hand left an ugly puckered scar close beneath the eyebrow which was long in healing. The present operation, he remarked, was that of Hess and might be considered in some respects a modification of Panas' since a double fold of skin was drawn up and became attached more or less intimately to the frontalis; he thought it was, as seen, a simple operation, the healing was rapid and the results good and apparently permanent. The position of the lid was only normal when the gaze was directed straight forwards and any looking up or down a deformity would still be apparent since the movements of the lid would not follow those of the globe.

The patient left the hospital within a week and the parents said they were amply satisfied with the result.

The Removal of King's College Hospital.

The South London site of twelve acres known as "The Sanders' Estate," which has been presented to King's College Hospital, is at the foot of Denmark Hill, close to Camberwell Green, and in close proximity to three railway stations. The electric tram-lines also run close to, and a new line is now being laid down which will pass the doors of the new hospital, so that the situation will be easily accessible from every district of South London. It is to be hoped that the £300,000 required to carry out this scheme will be forthcoming at an early period.

Notification is given of an intended application to Parliament next Session by the president, vice-presidents, and governors of King's College Hospital to leave to bring in a Bill authorising them and the committee of management to sell, lease, and otherwise dispose of the hospital and site. The Bill will contain clauses providing inter alia, that upon any sale, letting, &c., of the chapel erected in the hospital, or any other portion of the site which shall have been consecrated as a burial ground, the chapel and any part of the site so consecrated shall vest in the purchaser, &c., freed from all disabilities and restrictions; authorising the president, &c., and the committee to make agreements with persons having estates in the lands, &c., forming part of the site for the acquisition by the former of such interests; and empowering them to purchase, lease, &c., any lands, &c., suitable or convenient for a hospital and maintain on such lands or any of them a hospital, with all buildings and appurtenances which may be deemed necessary or desirable for the purposes of such hospital, and a medical college connected therewith.

The Medical Press and Circular.

WEDNESDAY, DECEMBER 2, 1903.

THE REGULATIONS OF THE CENTRAL MIDWIVES BOARD AND IRISH MATERNITY HOSPITALS.

The President of the Obstetrical Section of the Royal Academy of Medicine in Ireland did a very substantial service to the great Irish maternity hospitals when he devoted his Inaugural Address to the all-important subject of the regulations of the Central Midwives Board. Not alone did the address itself serve to draw public attention to a matter of importance and urgency, but by giving rise to the discussion which followed, and which was taken part in by the heads of the different maternity hospitals, it led to an expression of opinion, both general and strong. Our readers do not require to be told at any great length what are the present points at issue between the Central Midwives Board and the Irish maternity hospitals.

At the time of the passing of the Midwives Act, on many occasions we urged upon the authorities of the different hospitals concerned the importance of making a firm stand and insisting upon the recognition of their certificates. This stand was not made, and, in consequence, the Act was passed in its present form. It is true it compelled those into whose hands the working of the Act was entrusted to grant the same facilities for registration for a space of two years to nurses trained in the Irish maternity hospitals as they did to all women who, at the time of the passing of the Act, practised as midwives, whether trained or untrained—a most valuable privilege! It, however, contained no mandatory clause compelling the Central Midwives Board to continue this recognition. The result of this has been that almost the first act of the newly-constituted Central Midwives Board was to draw up for the training of nurses rules which cannot be complied with in Dublin, and which, consequently, shut out every Dublin trained nurse even from admission to the examination of the Central Midwives Board. At the discussion which followed upon Dr. Alfred Smith's address, the question was
LEADING ARTICLES.

Irish midwifery teachers, in the present rigid exclusion of the Central Board from the training of nurses in English hospitals. This and one which was accorded. It is an unpleasant thing to have to confess that all important set of the training of nurses without the training of midwives by the leading members of the Board. The truth is, we have no answer to the question: what hospitals have, we learn, in the Privy Council with one who has not a midwife having a certificate to have complied with the requirements of the Board regulating the training of midwives. The attitude of the Board towards this not will enable the question to be answered. As we are unable to answer the question of the purposes of midwifery, we are unable to suppose the request. The midwife training of women who are women in the Board has not been found to be pathological. That while on the one hand a midwife is recognised by a midwife is not required for three months, during which she renders her services and who receives no other midwife. What is the task of the midwife is to present herself to the other hand, a nurse who has a midwife is again examined. Can any Board justify such an effect, or can any request of the slighted recognition? We do not think it is well to remember the time it is to be prepared for the Irish or preparing for what may be support of their right contestant. We have no doubt the Board of public and the third at the back of them all, they secure the united members of Parliaments both.

SLEEPING SICKNESS.

Of tropical medicine in the men of science and to practical colonists, has been the subject of sleeping sickness. Mysterious in origin and invariably fatal, it affected large numbers of the population in wide, though defined, areas. As nothing was known of its causation, and consequently of its possible prevention, there seemed to be no reason why other districts and regions might not be visited with the same appalling results as Uganda. Now, however, thanks to the insight and industry of Dr. Castellani and of Colonel Bruce and his colleagues of the Royal Society's Commission, the cause of the disease is sufficiently known to hold out good prospects of ultimate success in stamping it out. Immediately after the arrival of the Commission in Uganda, Colonel Bruce was informed by Dr. Castellani that in five cases of sleeping sickness he had observed trypanosomes in the cerebro-spinal fluid. This, in itself, was a clue of great importance, since trypanosomes had previously been found to be pathogenic in man, though rarely found in man. The first observation of trypanosomes in the blood of mammals was made in the case of a rat by the late Dr. Timothy Lewis in 1877. A few years later its connection with the disease "surra," occurring in horses, mules, and camels, was made out by Griffith Evans in the Punjab. In 1896, Bruce established the causation of the "fly disease," or "nagana," affecting horses in South Africa, to be due to infection with a trypanosome carried by the tsetse-fly. Later still, the presence of a trypanosome in human blood associated with the production of fever and other symptoms has been noticed in West Africa. Other pathological conditions said to be due to infection with trypanosomes are "dourine" and "caderas," diseases of horses in the Near East and South America respectively.

Following up these clues, Colonel Bruce's colleagues, Drs. Nabarro, Greig, and Wiggins, found trypanosomes in the cerebro-spinal fluid of every one of ninety-three cases examined. In no case other than sleeping sickness was the parasite discovered in the cerebro-spinal fluid. Again, in every case of the disease the parasite was found in the peripheral blood; but now an apparent difficulty arose, for it was found in many persons who showed no symptom of sleeping sickness. Further examination, however, entirely dispelled this difficulty, since trypanosomes were only found in the blood of persons residing in the diseased area, and, therefore, subject to infection. Colonel Bruce believes, and probably rightly, that these people had been infected, and are liable to develop the disease; symptoms will appear when the parasite obtains access to the cerebro-spinal fluid. A monkey inoculated with cerebro-spinal fluid containing trypanosomes developed sleeping sickness, and showed the parasite in its blood. Similar results occurred on injecting trypanosomal blood into another monkey. Having established very fairly the causal connection between the trypanosome and sleeping sickness, the Commissioners proceeded to investigate the life-history of the organism. In this they were so fortunate as to have the co-operation of no less than four hundred
and sixty officials and missionaries throughout the country. The analogy of the disease with nagana was so obvious that the indigenous biting flies were made the subject of close study. It very soon became apparent that there was one particular biting fly—*Flossina palpalis*—which geographically was accurately associated with the presence of sleeping sickness. The habitat of this insect was the wooded shores of the lake, the neighbouring islands, and a considerable stretch of the River Nile. These were precisely the regions in which sleeping sickness prevailed. Experiments made to establish the connection of *F. palpalis* with sleeping sickness are not yet conclusive, but everything points in that direction. Monkeys were infected with sleeping sickness by the flies from the lake-shore in the sleeping sickness district, and attempts are being made to infect them by flies fed on the blood of patients suffering from the disease. Colonel Bruce and his colleagues are to be congratulated alike on the scientific methods of their investigation and the brilliant success which has crowned it. The habits of the fly have still to be studied with great care, but we have no doubt that methods will be found by which its numbers can be greatly diminished. The analogous case of malaria, and the success which has attended the destruction of the breeding-places of the anopheles at Ismailia and other places, give us every promise of equally useful preventive measures against sleeping sickness.

MEDICAL JOURNALS AND LAY READERS.

The correspondence columns of the great modern newspapers reflect more or less faithfully the many phases of our complex modern life. They cover, therefore, a wide field, and furnish an abundance of interest to a multitude of readers. Their financial and editorial importance, indeed, is so testified by the amplitude of space devoted to this strongly developed feature of modern journalism that there is no need to labour the point further. The supply of topics is clearly just as inexhaustible as the shifting kaleidoscopic combinations of society. For all that, the imagination of editors from time to time shows signs of satiety, judging from the curious nature of particular subjects chosen as the shuttlecock of these ephemeral discussions. Medical matters receive a fair share of attention, a fact that is not altogether surprising when one reflects upon the vast interests directly or indirectly connected with medicine that exist among the community. At any rate, nothing seems dearer to the lay editor than a correspondence upon some new or strange method of treatment, upon vivisection, upon the policy and management of a hospital, upon medical aid societies, upon the cure of consumption, upon the causation of cancer, or upon some other more or less technical subject which the omnipresent and omniscient amateur desires to illuminate and make clear. One of the most recent of these discussions has been raised by an "indignant" correspondent, who wrote denouncing the practice of keeping reading rooms of clubs, hotels, and other places where young persons of both sexes were wont to gather in groups, under the guise of adjusting a table or of examining the position of a child woman. Possibly "Indigent" of his time in a newspaper that is proverbially try to cover every case of moral outrage, and weighted with the sense of responsibility, can find no fault in the mass of details to be found in the newspapers. In seeing the disclosure of simple facts by thinkers at home, to know that a nation is won over to the flag of common sense; that points of sexual physiology are a part of a wider and more general public interest than is ever before known; this is a danger to the mental and physical health of the younger generation, and the substitution of "persons" for "stomach" for "bell" and the use of the more robust terms is the habit of calling a spade a spade. Probably the best out-spoken descendant of this vigorous and fastidious attitude of youth is the French picture books in medical journals in all their淫秽, a generation.
Current Topics.

Holmew's Hospital.

The Press recently made the mention of St. Bartholomew's at site met with the approval of this. This statement is so far from the facts of the case that in the duty not to enter a strong and well-informed the description of the Medical Press and the alternative scheme of a modern hospital in the saving behind in the City for accidents and reasons for that advocacy unmerited and discussed in the Journal during the past year. A careful detailed answer to the alternative of decentralisation committee brushed the matter shion. Sir Henry Burdett illusion to the alternative of a medical staff coming into the light of day, and elsewhere in our columns, ention of present site chiefly at hand of a huge day popu-trongest argument advanced.

The issues involved are of importance, and the Mansion in their recommendation views of the medical staff.

Without asking for an additional sum of funds to extend and rebuild on the basis of a huge additional sum of funds to divert the stream of saving hospitals. The least that can be done is to produce amelioration of every step that may College and St. George's to move into airier and by not St. Bartholomew's?

Use for X-Rays.

If we are to believe the matter better in France, "if we are to believe the some other things than those which are ordered better in countries, and one of these for criminals. The system of collected by the Paris police with a system has been good in other countries, and improved. It is well known. M. Bertillon of the individuals was used for police purg before the London police. A few months ago much to this important mark of conviction in London of a from the principal item of correspondence shown by a dirty window at the scene of the burglary with his "signature" in the archives of the police authorities. In Paris every convicted person has to undergo such a thorough anthropometric examination that it is difficult afterwards to make any mistake as to the identity of anyone who has ever been convicted. Not content with the completeness of their knowledge concerning past and present convicts, the police are now proceeding to compile particulars of the still unconvicted. Some 16,000 radiographic plates of various pathological conditions have been collected from the various hospitals of Paris in order that as much information as possible may be at hand to aid in identifying future criminals. This assumption that every citizen may become a criminal, though not without its humorous side, is probably as true as the copy-book maxim regarding the contents of the soldier's knapsack, and at any rate its application shows a thoroughness in the methods of the Paris police from which our own officials might learn much.

Compulsory Notification of Tuberculosis.

A marked step in advance has been taken by the approval by the Select Committee of the insertion of a series of clauses dealing with the prevention of tuberculosis in the Sheffield Corporation Bill. These clauses propose to deal with tuberculosis on practically the same basis as the scheduled dangerous infectious diseases are dealt with at present under the Public Health Act. The Corporation have sought and obtained powers for compulsory disinfection of all infected articles and houses under the usual conditions as to entry, and the usual limitation as to compensation for damage. The most important provision from the point of view of the medical man, however, is that notification of tuberculosis of the lung is made compulsory, and that whilst paying the medical certificate fees the Corporation can insist on information as to cases of the disease being sent to them under the same penalties as under the Public Health Act. The granting of these powers is limited to a period of seven years, at the expiry of which time they will need to be renewed if the experiment has been satisfactory. The significance of the approval of these clauses by the Select Committee is increased by the fact that the Local Government Board sent one of their medical staff to give evidence in favour of compulsory notification, an event that shows that the hitherto established policy of the Board has been reversed. The late Sir Richard Thorne was strongly opposed to dealing with tuberculosis as with the other infectious diseases, although he was one of the most ardent advocates of stamping out tuberculosis by administrative and missionary efforts. Mr. Power, his successor, held the same views, but now that he has relaxed the stringency of the official opposition other corporations will doubtless press for similar bills. It may be well to wait and see the result of the Sheffield experiment, for hitherto voluntary notification has not had any marked influence on the death-rate; and it would be advisable to have the system thoroughly tested under voluntary effort before resorting to compulsion.
NOTES ON CURRENT TOPICS.

Old Age—a Disease.

Professor Metchnikoff will always command a respectful and interested hearing from medical men by reason of their sense of his valuable researches, his enthusiasm, and his learning. When, therefore, he sets forth with every evidence of conviction the startling theories which his new work—"The Nature of Man"—propounds, one is bound to pay grave attention to them and the facts that are urged in their support. With much earnestness he enunciates his view that old age as we know it is a pathological state, and not a physiological failure of vital activity. And what is the agency that brings about this disease? We can be hardly surprised that Professor Metchnikoff blames his own child—the phagocyte. The phagocyte, not finding sufficient micro-organisms to occupy his time as age creeps on, turns to the tissues for his pabulum, with the natural result that those tissues undergo premature degeneration. Were it not for this factor in the economy of the individual there is no valid reason why life should not be prolonged to twice three score years and ten—a hundred and forty being the exact age that Professor Metchnikoff fixes. A curious correlation of this prolongation of existence, he explains, would be the development of an instinct of death, which would rob approaching dissolution of its terrors. If we could get rid of the phagocytic influence, in fact, we should reach the end of life so naturally that we should come to look on death as the next step in existence, just as sleep succeeds a long and tiring day. Professor Metchnikoff's work is a study in "disharmonies" left and wrought in man by the process of evolution; but one wonders if the harmony between men would be increased if we were all Nestors.

Another Hospital Scandal.

While what is known as "The Granard Nursing Scandal" seems still as far as ever from a satisfactory termination, there comes news of a scandal of almost equal magnitude in the management of the Sligo Fever Hospital. In this case the entire blame seems to rest with the Managing Committee of the institution. It appears that for a long time it has been evident that the drainage of the hospital was in a very bad state, if, indeed, it could be said to be drained at all. As, however, the hospital was nearly empty, there did not appear to the Committee to be any need to proceed with haste. They were, indeed, in some difficulty, as they were engaged in a squabble on the one hand with the Sligo Corporation, and, on the other, with the ground landlord. The latter objected to a drain having been made on his lands without his consent, and to his prejudice; while the Corporation refused to allow the hospital sewage to enter the public sewers of the town. Nothing was done, and at the present time, owing to a sudden outbreak of fever, there are nearly fifty patients, suffering from typhus and typhoid, crammed into the undrained building. "It was always a scandal, but now it is a disgrace," is the judgment of Dr. McCarthy, the Local Government Board inspector. "The discharge and all the debris from round the foundation of the building are dangerous, and li doctors and nurses in constant sickness." It will hardly be of such a report as this, devising a remedy, devote acrimonious discussion or remuneration of a temporary nature. Finally, we understand, impressed on the Committee with the death occurring among them could be indicted for malfeasance to open temporary sewage institution until a permanent one is down.

Presentation to
Dr. Alexander Gordon.

A few days ago a presentation was made by his friends, who desired gratification at the result to which he was a party at which reference has been on several occasions. The subscribers, having follow feelings of intense sympathy assurance of Dr. Gordon offered their hearty congruity in which he resulting in their complete tenance of his character and integrity, and his unsullied profession to which he be reply, said that the kindne had made a deep impress this further expression of was proud to know were several years' standing—w to compensate him for it and overcome. Subsequent entertained at supper. It were proposed and respon the vice-chairman, and t

The Royal Commission

The Royal Commission. 1901 to investigate the that had affected certain England has completed that the arsenic found its certain brewing sugars, tarnished by arsenical sunitons of arsenical glucose as by the firm at fault were. The symptoms of arsenica cussed, and it is suggested a complication should be in all cases of so-called alc epidemic at Halifax, in might be contaminated exposed to the fumes of Berzelius' process of ana detecting the presence 1,000,000th of a grain
The Sore Throat Epidemic at Woking.

An interesting and valuable report has been recently issued by Dr. R. W. C. Pierce, Medical Officer of Health for Guildford and Woking. It deals with a severe and widespread sore throat epidemic that recently prevailed in Woking. The first intimation of the outbreak came early in October, when several swabs from infected throats were transmitted to the Medical Officer, but no diphtheria bacillus was detected. Towards the end of October the great increase of the epidemic, together with several deaths, led Dr. Pierce to make further investigations. The cases were severe, the glands of the neck were swollen, and in some instances abscesses formed both internally and externally. Fever and other signs of general septic infection were present. Dr. Pierce was enabled to trace the source of the infection to two local milk dealers, and from thence to a farm at Chertsey. On visiting the farm in question he found several cows suffering from suppurative mammitis. The organisms obtained from the pus in the teats were chiefly staphylococcus and streptococcus, corresponding with those obtained from Woking throats. This report furnishes overwhelming evidence, if any were needed, of the absolute necessity of stringent inspection and control of milk at every stage from the teat of the cow to the table of the consumer. Whole armies of our citizens have been destroyed in the past by milk epidemics of enteric fever, scarlatina, and diphtheria. Yet the same unscientific recklessness continues as a standing reproach to the efficiency of our modern public preventive service.

The Therapeutical Society.

Of the many societies that have sprung into existence of late years the particular one devoted to the study of therapeutics appears to demand the least amount of justification. The avowed aim of the Therapeutical Society is to furnish an opportunity for the collective investigation of remedies, new and old. In spite of the growing tendency on the part of medical men to turn less and less to the specific virtues of drugs "to be taken three times daily" there can be no gainsaying the fact, on the other hand, that now and then a valuable remedy is discovered amid the vast rubbish heap turned out every year in Germany and in other parts of the world. In the present issue of THE MEDICAL PRESS and CIRCULAR will be found two valuable original communications recently read before the Therapeutical Society. The first was by Professor R. B. Wild, of Manchester, on the "Pharmacology of the Saponins," while the second, by Dr. Stapf, of Kew Gardens, dealt with the "Botany of the Indian Aconites." Dr. Wild showed that quillia bark contains two active saponins, quillaic acid and quillaia sapotoxin, both of which are general protoplasmic poisons. After a variable period of irritation, they paralyse muscular tissues, and even in very dilute solution they cause spasm of vascular and all other contractile tissues. The action on the isolated frog's heart is marked. The
organ remains in a partially contracted state, and gives small regular beats without being fully relaxed. If a strong solution be used the heart quickly stops in a contracted state. The moral is that quillia, which is often added to a mixture for its emulsifying and suspending qualities, may be in reality a dangerous drug.

The Action of Eucalyptus Oil.

The active principle of eucalyptus oil, namely eucalyptol, acts in many ways like other essential oils. Thus, when applied externally it is rubefacient, and when taken internally it is a carminative, a stimulant and an antiseptic. But it also possesses other actions peculiar to itself. It stimulates renal excretion, and it has been credited with certain feeble antipyretic and anti-malarial properties, acting in the latter sense somewhat like cinchona. In poisonous doses its effects are more variable, and, as a matter of fact, it does not figure largely in works on toxicology. In the case of an adult, reported by Mr. Ernest Sheaf, (a) of Queensland, who took five drachms of the extract of eucalyptus, the patient was seized with involuntary muscular twitches, faintness, and tachycardia. The following day the urine became of a dark colour, but the man made a complete recovery. The recent case of Hall v. Bruce's, Limited, in which the plaintiff sued a firm of chemists on behalf of his infant son for having been supplied with eucalyptus oil instead of a cough mixture, and was awarded substantial damages, illustrates the effects of large doses of the oil. It was stated that a drachm had been administered to the baby, who was forthwith taken severely ill, but it was noticed for some months afterwards that the child suffered from irritability of the bladder and incontinence of urine. This latter symptom, so common in childhood, does not generally appear at quite such a tender age, so that the probability is that the eucalyptus was in some way connected with the loss of vesical control. The case was rather an unusual one, in that the bladder symptoms dated directly from the administration of the drug. The oil will, in some cases, act upon the kidneys in a similar manner to tar, so that it may be surmised that the incontinence was preceded by some more or less slight inflammation of the mucous membrane of the urinary tract.

A Rare Lingual Abnormality.

Cases in which the surface of the tongue presents curious, irregular marks, somewhat resembling the outlines in a map, are not very uncommon. These "geographical tongues" are sometimes the precursors of epithelioma, or they may be one of the late results of syphilis. A condition of leukoplakia may also be induced by chronic irritation within the mouth, of dental or other origin. A case is narrated by Dr. Levi Bianchini (b) in which the aspect of the tongue bore a strong resemblance to the convoluted exterior of the cerebrum. The patient, a farmer, aged 48, with good personal and family without any apparent causes, was taken by an involuntary convulsion, into a state of dementia, and form convulsions. It was an attack of a serious nature, and the tongue was noticed to be of a curious form. As regards its size, position, and general surface presented a series of elongated white bands, scored by four median furrows. These lingual peculiarities persisted, and the patient was therefore, of congenital abnormality. He himself remembered the shape of his tongue in detail before the furrows were covered by the tongue membrane, a point of some importance to distinguish them from the inconvenience of any kind which the patient might suffer from. A teratological condition appears to be the correct term for this.

Old Age and

It must have interested the College of Physicians to know the means for the prolongation of life are getting old, and if rejuvenation can be accomplished, little thought and attention seem to be devoted to this subject, and it is not known over two thousand years since Hippocrates allowed that old age was allowed to medicine. Old age was not hurried off life's stage, but crowded behind it. Poor Chaucer practised the results of his art, if we were asked whether we have been long on earth, we had to admit that "those were young." It will certainly be a specialty arising, and then consult the experts who have studied the art of prolonging life, how old their fathers and how old the population from infancy. Fellows must have listened with interest to this lecture, and must have sat in awe, guarded by the very real interest, "as the subject is a people, especially if considered in the population from infancy to old age, how old they live in future times and what is the population from infancy to old age, how old they live in future times and what is the possibility of prolongation of life in a future time.

A QUESTION OF MORALS.

To the Editor of The Medical Press and Circular.

SIR,—I see in one of the daily papers, in the column, "The Editor's Post-bag," a letter headed "Doctors and Crime"; and the same kind of question is raised in the "Medical Gazette." I submit to the readers of The Medical Press and Circular last week, and which you considered to be "a question of the utmost importance from the point of view of professional morality." When we have to do with cases of mental weakness and see influences at work that in our opinion are injurious to the patient, it would be well that we should be clear as to our legal and moral obligations, and at least be parties to what is certainly wrong.

I am, Sir, yours truly.

THE HOMICIDAL HAT-PIN.

To the Editor of The Medical Press and Circular.

SIR,—An instance of the dangerous nature of the "homicidal hat-pin" came under my notice in July, 1902, when a gentleman came to me with the history of a wound in the eye from the prod of a hat-pin. The injury had occurred one month previously, and the vitreous humour was nearly quite taken up with blood clots. Vision was only 1/26. Fortunately the weapon happened to be aseptic, and the blood mostly absorbed, raising vision to 6/6 in some six weeks' time. The wound was in the sclerotic behind the position of the crystalline lens.

I am, Sir, yours truly,

J. B. STORER, F.R.C.S.

VIVISECTION.

To the Editor of The Medical Press and Circular.

SIR,—I think there are many practitioners who are more or less averse to vivisection. I should very much like to have a distinct answer to the simple question. Did you ever learn anything of use to you from vivisection? I have been in the lecture-room in Paris and have listened and looked, and have always come away in rather a doubtful state of mind, after seeing the miserable dog on the table, and hearing the more or less theoretic eloquence of the lecturer. To go from such a lecture-room to the bedside and try and bring the one into any kind of practical relation with the other has always seemed difficult, if not impossible. Whatever interest vivisection may have for the original investigator it is another matter when it is admitted as a necessary method in the education of those who are going to practice the profession of medicine.

How curiously varied are the results of vivisection among original workers must be familiar to many.

[Edgar Union.—An election was held to appoint a medical council vacant by the death of Dr. Hayes were Dr. Robert Martin, 1 Dr. Francis T. Herron, Lough- ing that the former gentleman guardians said that Dr. Herron Medical Association whereas Dr. had no intention of becoming so. Obtained 36 votes against Dr. Herron's 23, he was declared elected. As both candidates were dispensary medical officers under the same board, it will be interesting to watch the action of that board when the election of a successor to Dr. Martin comes on. A meeting is to be held on the 14th instant to fix the salary to be offered to that successor.

Health of the City.—During the month ending November 21st, 301 cases of zymotic diseases were notified in Belfast, including 93 cases of scarlet fever, 70 typhoid, 52 erysipelas, 49 simple continued fever, 20 diphtheria, 6 membranous croup, 4 each typhus and typhoid fever, and 3 small-pox. The deaths from these diseases numbered 54, and from phthisis and diseases of the respiratory organs 220. The annual death rate from all causes was 17.9, while in the corresponding period of last year it was 21.4. Sir P. This report was published another case of small-pox has occurred, the patient being a working man lately come from England.

Correspondence.

How curiously varied are the results of vivisection among original workers must be familiar to many.
If some of your readers would honestly state what they have learnt from vivisection it would be very interesting.

I am, Sir, yours truly,

ROBERT LEE.

INQUEST AT DRUMCONDRA HOSPITAL

To the Editor of The Medical Press and Circular.

Gentlemen,—I am requested by the police to attend an inquest on the 23rd ult., at the above hospital, to give evidence. I got no subpoena, but it was put on my slate, by the police, to attend. I am always anxious to assist the police, but I would like to know, was it my duty to attend? The Doctor in charge of the case, Dr. McCullagh also attended. The Coroner, Dr. Louis Byron, for whom my profession has the greatest respect, asked the jury would myself and Dr. McCullagh be examined. The foreman, on taking a division, verbally announced that a majority of the jury wished myself and Dr. McCullagh to be examined. Consequently foreman signed an order for our fees. Dr. Wilson, one of the visiting attendants to the hospital, made a post mortem and gave evidence, and I understand he gets no fee.

I would be glad to hear from some of your readers the rules in such a case. Should Dr. Wilson get a fee?

I am, Sir, yours truly,

THOMAS P. COOR,

[The manner in which Dr. Codd was summoned to attend the inquest was undoubtedly irregular. If the patient died in the Drumcondra Hospital Dr. Wilson is not entitled to a fee.—Ed.]

REPORT OF THE MEDICAL COUNCIL OF ST. BARTHOLOMEW'S HOSPITAL WITH REGARD TO THE PROPOSED CHANGES.

To the Governors of St. Bartholomew's Hospital.

Gentlemen,—We desire to call your attention to the urgent necessity for a large increase of accommodation in the various departments of the Hospital, and the need of securing an adequate amount of space for future development. This can only be provided for by the purchase of the whole site of Christ's Hospital.

On November 2nd, 1899, a deputation from the Medical Council urged upon the Treasurer and Almoners our conviction of the necessity for the acquisition of the whole of the site of Christ's Hospital. They told us our belief that the portion of the site asked for, about an acre and a half, would be quite inadequate, and that if this opportunity of gaining the whole site were lost the proper growth of St. Bartholomew's would be hampered for all time.

On August 15th, 1899, the Medical Council had submitted, at the request of the Treasurer, a full Report on the seriously defective state of the accommodation of the Casualty, Out-patient and Special Departments, which together make up a very large part of the service of the Hospital.

We would draw your attention to this Report, which showed that the Out-patient rooms, and rooms for Special Departments, have become insufficient for the work which has to be done in them, and that, for the proper treatment and welfare of the patients, a complete reorganisation is required. The Surgery, consisting of the large room, with smaller rooms attached, accommodates every morning an Assistant Physician, an Assistant Surgeon, a Casualty Physician, a Dental Surgeon and his Dressers, five Assistant House Physicians, ten House Surgeons and the Ophthalmic House Surgeon, forty Surgeons' Dressers, Sister, Nurses, an Inquest Officer, and Porters. When filled the department holds more than 600 people, and, in spite of the promptitude with which the work is performed, the places of those who go out are at once occupied, and the room remains crowded on some mornings from 9 o'clock until nearly noon. In the afternoon the Surgery accommodates the patients sent for consultation to the Surgeons, to whom are allotted after 1.30 the small rooms used in the morning by the Casualty and House Physicians. On certain days these rooms are subsequently used by the Surgeons to the Orthopaedic and Throat Department by the House Physicians. The body of the room is of accidents and urgent cases as a waiting room and patients by the officers in charge of the Special Departments, Aural, Throat, and posses the Report shows unsuited. Vide Report.

As a receiving room it is large enough, in proportion generally and its Staff, simple because its function those also of a waiting, in addition to those of a classroom examination and treatment things can only be remitted extensive series of indefinite Special Departments, and of the whole Casualty include the provision for which I can examine and treat the patient. The Report further states that the rooms, Medical and Surgical, are small, ill-arranged, and inefficient carrying out of the patient and Special Departments sufficient.

Each department really treatment of its patients in particular apparatus. Orthopaedic are totally Ophthalmic Department, those of the Skin.

In the Medical, Surgical and the Casualty Departments, and the insufficient nurse defects of propriety in the lighting, heating, equipment, furnishing, art and skill required in the perf, are altogether defective. Savy waste of time in the patients, who are sometimes for a very long time waiting.

The work done is increased, and must continue to be done by the assistance of medical and surgical causes the want of space, accommodation and apparatus.

The Report did not call for a complete reorganisation of the Nurses' Home. The accommodation is as inconvenient as it has been of great service and consists of old houses, but the immediate prospect of improvement is good.

At least three new operating theatres are needed. Their need may be seen in the total number of major operations performed at Bartholomew's Hospital, whilst it is not possible to infer from the anaesthetics, were administered.

Isolation blocks are essential for the protection of the inmates of the Hospital. A new Mortuary is essential. There is no provision in the existing building for means of showing that bodies of the dead which are no longer of public interest.

Space is also required for Research Laboratories which are now said to be proving very essential. The wards are not connected with modern ideas of hospital construction.

ing, in which he achieved considerable success.

LITERATURE.

MATHews ON DISEASES OF THE RECTUM,
ANUS, AND SIGMOID FLEXURE. (a)

It seems a great pity that in bringing out the third
edition of this work the number of illustrations was
not more largely added to, as the present number
of pages is far too small for a book of the
kind, especially as the majority are cuts of instruments.
The chief value of this work is due to the fact that it
includes the history, symptoms, and treatment of a
large number of cases, and that many of these
are instructive and form interesting and occasionally
amusing reading. The following anecdote Dr. Mathews
tells as occuring early in his practice: — "I was sent
for to come hurriedly a distance of several miles to
see a child to which had happened some terrible acci-
dent. Upon my arrival I found the mother in great
distress. She said to me between her sobs that the
body of her child had come down and that she feared
it was in a dangerous condition. The little fellow was
lying on the bed, and I could see the prolapse before I
got to him; my first impulse—which I carried into
execution—was to pick him up by the heels and shake
him so that the prolapse might go back by gravitation.
No sooner had I done this, than the mother, appro-
aching from behind, dealt me a terrific blow on the back
of the neck and knocked me down. When I fell, with the
child under me, but when I regained myself and lifted
him up, the prolapse had disappeared. Of course she
begged my pardon, but it did not relieve the sting."

We cannot help thinking that the author takes a
rather too gloomy view of expectation in the case
for cancer. He sums up his remarks as follows: "It
will be seen, then, that the operation does not hold
forth any great inducement, and a surgeon should con-
sider well his case before undertaking it."

We must confess some surprise at the author stating
that lumbar colotomy is his favourite operation in
the majority of cases where a colotomy is demanded.

In speaking of malignant diseases of the rectum,
Dr. Mathews says: "But as we are dealing with malig-
nant tumours, or, to speak more properly, with can-
cerous tumours of the rectum, we shall not refer to
the word 'saccula.' I recognise the in-
timacy of resemblance between a sarcomatous tumour
and cancer is so close that the microscope will often
fail to decide, and I believe that it would be impossible
to distinguish between them without a reference to the
clinical facts in the case." We are at a loss to under-
stand the above, fora sarcoma is popularly a "cancer"
and the microscopic distinction between a sarcoma
and a carcinomia in the rectum should present no diffi-
culty.

MODERN BULLET WOUNDS (b)
The subject of this brochure is one of special interest
at the present date, after the uniquely novel and trying
experiences of the late South African War. The piece
for which the original essay was written is that given
griennally by the trustees of the Alexander Memorial
Fund, which latter was founded to perpetuate the
memory of Thomas Alexander, C.B., Director-General
of the Army Medical Department from 1848 to 1866.
It is of some interest to note that the subject of the
essay before us was chosen before the Boer War began.
Ordinary surgical details—"the condition of surgeons"—are omitted; and, of course, very

Judiciously. With regard to the projectile, whose efficacy forms the text of the document before us: "It is not only the bullet, however, which has been altered—the rifle and explosive have participated in the new order. By better rifling and improved explosives (acting in conjunction with diminution in the rest's resistance of the air owing to the smaller front presented by the projectile) a greater speed has been attained; also a flatter trajectory—this last being more likely to make a difference in the number wounded than to affect the character of the wound." The field thus laid open for discussion is a new and instructive one; and we recommend the writer's treatment of his fertile subject to all practical surgeons.

Medical News.

Attempted Murder of a Medical Man.

Mr. George Whittingbury White, junior resident medical officer at the Union Infirmary, Fir Vale, Sheffield, has been the victim of a murderous attack by a man named Edward North. The man complained of pain in his ear, and while Mr. White was examining him drew a knife and struck at Mr. White's head. Mr. White escaped the first blow but the second caught him in the ear. North was at once felled and secured by the attendants. The man appears to have nursed a grudge against the medical officer because he had on a previous occasion certified him as able bodied and fit for work. He had only recently been released from the gaol where he had served a sentence for burglary. Mr. White's ear has been described as a punctured wound about an inch long and three quarters of an inch deep extending backwards from the lower border of the left external auditory meatus towards the mastoid process. It is now healing well and will probably cause no permanent injury.

Society of Apothecaries of London.

The diploma of the Society was granted to the following candidates, entitling them to practice medicine, surgery, and midwifery: S. Bentley, F. M. Boocet, F. Hansen, W. B. Harris, P. S. Klots, P. J. Pagonis, F. A. Pettavel, C. H. Pring, and L. S. Shoomath.

University of London.

The pass list for the M.B. examination for internal and external students of the University of London has just been issued. In the first division the successful students were William Fraser Annand, University College; Mary Cecelia Bell, London (R.F.H.) School of Medicine for Women; Clement W. Chaplin, London Hospital; Ernest Edgar Maples, St. Bartholomew's Hospital; Agatha Parson, London (R.F.H.) School of Medicine for Women; Charles Derwent Pye-Smith, Guy's Hospital; William Arthur Rees, Middlesex Hospital; Charles Newton Sears, St. Thomas Hospital; Arthur Rendle Short, B.Sc., University Colleges, Bristol and London; Mary Townsend, London (R.F.H.) School of Medicine for Women; Hugh Watts, St. George's and Guy's Hospitals; Owen Thomas Williams, B.Sc., University College and R.I. Liverpool, and Guy Theodore Wrench, Guy's Hospital.

Death Under Chloroform.

The Leicester coroner recently conducted an inquiry into the circumstances of the death of Alfred Henry White, aged 43, of Dowlias, which occurred at Leicester Infirmary under the influence of an anesthetic. Deceased was admitted on October 28th suffering from cirrhosis of the liver, and it was arranged that he should undergo an operation. On Thursday last he was examined, and was deemed by the medical staff to be in a fit condition. Chloroform was accordingly administered, but when the second stage was reached he collapsed. Artificial respiration and stimulants were applied, but without effect. The jury returned a verdict of 'Accidental death,' and exonerated the medical staff from blame.

The Indian Medical Service.

The Secretary of State, on the recommendations of the Government of India, has approved a revision of the rates of pay and other concessions to the Indian medical service. The conditions of service under the new scheme provide for:

Rates of pay—lieutenants, Rs. 1,200 per annum; lieutenants after five years, Rs. 1,400; lieutenants after ten years, Rs. 1,600; lieutenants after three years, Rs. 1,250; lieutenants after five years, Rs. 1,500; lieutenants after ten years, Rs. 1,750; lieutenants after three years, Rs. 1,250; lieutenants after five years, Rs. 1,500; lieutenants after ten years, Rs. 1,750. (2) Soldiers' pay of lieutenants to be Rs. 1,200 per annum. (3) Lieutenants will be eligible for promotion to the rank of major after five years' service. (4) Special leave for purposes under certain conditions to be leave of absence. (5) A leave lodging allowance to lieutenants of Rs. 50 per annum. (6) The pensions now admissible to lieutenants of 17 years' and 20 years' service will be Rs. 2,000 and Rs. 2,500. (7) Extra pay of lieutenants for service in the Frontier area will be Rs. 150 per annum. (8) These changes to take effect from July 1, 1903.

School of Medicine.

The Annual Dinner of the London School of Medicine for Women was held at 429, Euston Road, on Tuesday, December 4th.

Medical Rank and Pension.

The usual monthly meeting of the Medical Rank and Pension Society was held at 429, Euston Road, on Tuesday, December 4th.

Public Vaccinator and Loc.

It is reported that Dr. Mason of Wisbech (Cambridgeshire) has been appointed as public vaccinator in accordance with the local Government's directive to vaccinate all children in three years of age at a fee of 1s. 6d. per head.

Marriages.

Deaths.

KEMPSTEAD.—On Dec. 4th, at 7 Redcliffe Villas, Surbiton, Elizabte Robinson Keensteild, aged 54, daughter of the late Richard Headlam Keensley, M.D.

MURPHY.—On Dec. 1st, at Spring Gardens Lodge, Gosport, Major Langton Philip Murphy, R.A.M.C., youngest son of the late Colonel Charles Murphy, in his 43rd year.
Original Communications.

NOTE ON THE PHYSIOLOGY OF THE UPPER RESPIRATORY TRACT.

By MAYO COLLIER, M.S.Lond., F.R.C.S.Eng.,
Senior Surgeon to the North-West London Hospital, and Ex-President of the British Laryngological Association, &c.

Physiologists assure us that the air in its passage to the lungs is somehow warmed, moistened and filtered, but how this change is effected has not been made clear.

If we survey the upper respiratory tract as a whole, we make out that its shape is peculiar, in so far as it presents from without inwards a series of marked constrictions and dilatations.

We have first the cone-shaped dilatation of the external nose, forming the vestibule.

The vestibule terminates opposite the nasal process of the upper jaw in the anterior opening of the nasal chamber, or anterior nares.

The vestibule at its junction with the nasal chamber becomes much diminished, so as to form probably the narrowest point in the whole respiratory tract.

The shape of this opening is a compressed ovoid. It is bounded by rigid and inextensible walls, and is quite incapable of expansion or alteration in size. We have an anatomical fact of some interest: that the inlet is the narrowest or most constricted part of the respiratory tract, and that this inlet is stiff and rigid, and cannot be expanded. By this evidently a limit is placed on the amount of air that can pass to the lungs via the nose. Following on this extreme constriction we have the marked but irregular dilatation of the nasal chamber. The extent of this chamber is not apparent at first sight, and it is only when we have taken into consideration the several large spaces that lead into it, that we can form any estimate of its capacity. If we take into consideration the frontal sinus, the antrum with the smaller ethmoid and sphenoid sinuses, the air capacity of the two chambers of the nose cannot fall far short of fifteen to twenty cubic inches. Following on this remarkable dilatation is an equally remarkable contraction of the posterior nares.

This opening, unlike the anterior, is variable in size, and alters considerably within narrow limits. It is crescent-shaped and varies with the size of the posterior end of the lower turbinal body. When much dilated the turbinal body can completely close this opening.

Following this second constriction is a second marked dilatation, that of the pharynx, which extends from the base of the opening of the larynx.

The capacity of this dilatation is considerable, amounting, probably to ten cubic inches. This dilata is a third constrictions, that of the larynx, and this constrictions, becomes more marked as the glottis, or "narrowed" of the trachea.

On looking at the respiratory tract and dividing it into the external respiratory tracts, we note that a natural division, but that constitutes has at its entrance a very large and important organ.

The valve guarding the opening formed by the cartilages and muscles of the lower animals this valve, and well marked, and is mammalian.

Most individuals can close the wings of the nose at will, or at practice.

Guarding the opening of the tract is a valve so perfect in is capable of completely obliterating the respiratory tract either will of the individual.

The question arises, What is the place on these successive constrictions? Can we see in their arrangement tendency to facilitate the passage of parts so and the breath of air without interference? These constrictions, with their effect and effect, and so prevent the egress of air without interference.

The act of nasal respiration is three and four seconds, but is accomplished in less time for the limited quantity only of air necessary to maintain respiration and if more is required and necessary the accessory organs must be made use of.

We thus see that nasal respiration is hurried beyond a certain point, or in the limit in the ability of the nostrils to moisten and filter air to the lungs.

The shape of the vestibule (i.e., the opening) is such that the largest quantity of air shall pass the anterior nares at.

Its rate of motion as into the posterior nares must be considerable, and spreads out in all directions from the nasal chambers.
AL PRESS. ORIGINAL COMMUNICATIONS. Dec. 16, 1909.

It ensures that the air shall not stream and so traverse the nasal ares at a slow pace and spread out in the interior of the nose, and takes of the previous warm contents shown to the pharynx at the comparrison. The constriction at prevents the nasal contents sudenly, and so allows time to mix and warm that enters the nasal flows in slowly until the tension of respiration has been equilibrated. At of respiration the air is drawn into the bronchi and

achea, larynx and pharynx will the place of the air displaced and the air in the nose will ough the narrow posterior nares. Air will flow in through to take the place of that which be pharynx.

accomplished by a series of dis- cold air from without partly the previous warm contents, the residuum becomes itself and filtered in turn.

ed half-warm air will pass on and possibly reach as far as the nose can take this place the act accomplished and the lungs are

factory Address TO THE AL STUDENTS OF COLLEGE, GALWAY. ION 1903-1904.

KINKEAD, M.D.Dub.

all not detain you by reference to ct of your studies further than to kng examinations is not the end and aim of your existence, but proceed to inquire why have you chosen medicine as your life’s career.

Not, indeed, for the ease with which a qualification to practise can be obtained; I know of no profession for which the preparation is so severe and extensive. As Mr. Tobin remarked in his Introductory Address one year at St. Vincent’s Hospital.* * * The student, if he wishes to qualify at all, is one of the hardest worked young men to be found. . . . a modern medical school is no place for an idle.

Is it from a love for science? That may attract some, for there is no branch of medical or surgical work which does not open up vistas for scientific inquiry and wide fields for original research. Have you chosen it from philanthropic motives—aided by the noble conception of curating the ills that flesh is heir to, relieving suffering and benefiting humanity? "The number of persons who-from purely secular or philanthropic reasons enter a profession is very limited. To the majority a profession is what the German call a bread and butter science—a means of livelihood; and according as the remuneration is good or there is scope for ambition, so will be the number of able men entering its ranks. Most men of talent and ambition enter the profession themselves, or have selected for them by their parents, that calling in life which holds forth the best and most numerous prizes in money or position. Therefore, I presume the majority of students have chosen medicine as a means of earning their bread, with possibly butter to it.

Now, there are one or two general principles which I wish to consider.

It is a doctor's right to give or withhold his services; his time, his knowledge, and his skill are his own to dispose of as he likes; he may make a free gift of them to the public in general or to anyone in particular; he may sell them to the best advantage he can; or he may let them decay and deteriorate by disuse.

The public does not seem to understand this, and one of the attributes attached by it to medical qualification is an excessive philanthropy—a fallacy strange to say, encouraged by the profession itself—in fact, the enormous and indiscriminate amount of charitable work done by the medical profession has had a demoralising effect, has implicit in the mind of the public the idea that it has a right to unlimited gratuitous medical aid, and has induced individuals and corporations to make demands on the time and skill of medical men that they would not dream of making on the property of any other citizen, and has led to the inadequacy of the remuneration for medical services.

When I say I am heartily tired of the constant chatter of the charity of doctors, I do not want you to mis-understand me; the command, "Thou shalt love thy neighbour as thyself," was given to all men, not to doctors alone. Medical men are bound neither more nor less than others to aid Suffering and humanity—

The afflicted ones who lie Steeped to the lips in misery, Longing and yet afraid to die; Patient, though sorely tried. Because the special knowledge you have acquired with much labour, after long years of toil, and with considerable expense, is your property, you are bound to give, and to give freely, but with discrimination, for indiscriminate charity, whether by medical services or gifts of money, is demoralising; and when you give it be of your best, the care, time and skill bestowed on the poor person whose case you undertake should be as ample as that you would afford to a millionaire; it is more essential that it should be so, for the rich can employ many doctors, your poor patient is solely dependent on you.

Having qualified and registered, you have the choice, broadly speaking, of private practice, the Army, Naval, or Indian Medical Services, or Civil or Colonial appointments, with or without private practice, of these I have only time to deal with the Irish Poor-law Service, promising, however, in all, and especially in the latter, you have before you a life of incessant mental and bodily
toil; in other occupations a man may call some portion of his time his own—it may be his Sundays, his hours of rest, or his meal times; a doctor is always on duty—his life is one of never-ending labour and exposure to danger; as regards the latter, in our own neighbourhood within the last couple of years Dr. Kean of Arran, and Dr. Conroy of Spiddal, have died, and Dr. Glyn of Turbough, happily escaped with his life, of typhus fever contracted in the discharge of dispensary duty.

What will you get for all this? In this respect I cannot do better than quote what I wrote in 1889—:

For the exercise of the highest faculties of man, as a field for the investigation of the most intricate, interesting, and ever varying problems, as affording unlimited opportunities of doing good to one’s fellows, medicine stands without a rival, and therefore has attracted, and will attract, to its banner some of the ablest, wisest, most self-denying and noblest minds of the world; but as a field for personal aggrandisement it stands on one of the lowest rounds of the ladder leading to wealth and rank. There is no other profession so absolutely indispensable to the public, yet it is the worst paid of all. There is none calling for a wider or a higher education, or that contains men of greater genius and culture, yet its social status is singularly uncertain and unequal. There is no profession that has rendered greater services to the State, or whose members in the discharge of their duties to the community are exposed to such daily dangers, or who exhibit more endurance, courage, skill, and self-denial, yet there is no profession towards which the State shows itself so niggardly in remuneration, so cheary in rewards. The church, the law, the naval, military and civil services, and the engineering trade, have rich pecuniary prizes, and are rewarded with peerages, patronage and honours; medicine has few prizes, and State appointments are poorly paid. The contrast is curious between destructive and life-saving occupations. The former, the King ‘delighteth to honour,’ but the physician or surgeon, whose genius has saved thousands, whose discoveries have driven deadly disease from our doors, whose industry has increased the existing, whose patients in the perfected, methods which have spared suffering to multitudes, is either ignored or (with one notable exception) granted the non plus ultra of a baronetcy or knighthood.

That I have not exaggerated two examples will prove. About 1877 a colliery accident occurred at Pontypridd, in Wales, by which four men and a boy were imprisoned in a heading, without light or food; they were driven from coal-damp and a flood of water. Doctors were in attendance in the pit along with the men actively engaged in the work of rescue, and were exposed to exactly the same peril, and therefore to the stimulus of bodily work to take off their minds from the depressing influence of surrounding circumstances. It is startling but true that the Albert Medal was conferred on the lay workers, and that the medical men who shared their peril, and cheered and encouraged them to persevere with their noble task, received no recognition from the State, for no comprehensible reason, except that they were medical men.

The loss of the guns at the battle of Colenso, and the gallant efforts of Roberts and Reed of the Royal Artillery to recover them in the face of almost certain death, is still fresh in our minds, and fills us with admiration.

About the same time, a deed as heroic in the face of danger as imminent was performed by two other Irishmen.

Typhus fever broke out in the Island of Arranmore, off the coast of Donegal; Dr. Smith, of Burtonport, the dispensary doctor, had daily, regardless of wind and sea, to row out to the island and attend the fever-stricken poor, savagely, the other inhabitants, being panic-striken, would not come near the habitation of the patients, and he was forced to act as nurse as well as doctor. It became necessary, in order to save their lives, that the fever patients should be removed to hospital, so grave was the panic. Dr. Brendon McCarthy, Local Government Board Inspector, volunteered brave men rowed out in a leaky boat to carry out the infection, and bore suffering from typhus to the hospital, was with difficulty baling till it sank just as it accomplished by two Irishmen was extreme—in both the ir sense of duty and honour—what the one lacked the other. Let this be a lesson.

While on Roberts and Conroy the soldier—never the Victoria Cross as promptly they had served so well, no of any kind was conferred by on Smith or McCarthy.

That the value of the service confers on the community is places, and that its pecuniary value is not altogether due itself, from a competition for ordinary private practice, is found by experience. That results chiefly from the high fees. This effective when it is the result of the sick. Hailey, doctors are begin work, like all good work, when the vendor has a voice as well as their wares are absolutely in and that if they are to get a thing, money is the only way.

Probable what has brought a combination with the medical of the Army Medical Service on the more the condition, the Royal Army favourable career to able and

tious disease to the Local Government Board, and discharge duties under the Labourers' Act, &c. He cannot go out of his district without leave and getting some doctor to take his place, for he is always on duty and at any hour of the day or night must attend on the holder of a ticket.

The amount of work, including the time spent in travelling, varies according to the population and area of the districts; in none is it light, in most it is arduous in the extreme.

The tickets issued in the year 1900 were—

For attendance at the dispensaries 447,213
For attendance at the patients' homes 191,778

giving an average for each medical officer of 530 and 200 respectively.

You are now in a position to form some idea of the demands of duty on the dispensary doctor, but I doubt if anything but experience could make you fully realise the hardship and slavery of the life: long drives, tramps on foot over moors and mountains, by day and by night, on week-days and Sundays, summer and winter, in driving rain and drifting snow, with weary waiting, often in wet clothes, in miserable cabins or foul rooms where the poor unhappily are forced to dwell.

What will you get for it? I have worked out some figures for you from the Local Government Report for 1900. The lowest salary I have found is £2914s. 10d. per annum out of the wages of a day-burner; the next rate is £165, which insufficient salary is given for exile to the Island of Bofin. The average salary is £108 12s.; the average vaccination fees work out at 9s. 6d.; and what are called temporary guardians who get £1 1s. 6d. per annum; the average payment of the dispensary doctor is £130 12s. per annum, out of which he must pay rent, taxes, and the expenses of working his district. Let us compare this with the payment of bank clerks, who are not by any means an over-paid class of men.

A bank clerk does not require an expensive professional education, he enters the bank at seventeen or eighteen years of age and begins earning at once; and his earnings twenty-three or twenty-eight years of age are in receipt of at least £130; his hours of work are not excessive, his time is his own once he leaves the bank's door; his Sundays are days of rest, he can sleep at night without fear of disturbance; besides official holidays he gets vacation each year, his pay increases, he is certain of promotion, is sure of a pension.

The doctor receives no increase of salary, there is no promotion, he cannot calculate on a pension, and out of his expenses he must pay the interest on the capital expended on his education should be deducted.

The bank clerk is pecuniarily better off, and has not a tenth part of the work and none of the risks which fall to the lot of the dispensary doctor.

It is true that the dispensary doctor is allowed to engage in private practice; there are, however, many districts in which the practice, like Mr. Bob Sawyer's, is one in name only, and where there is any worth having the public and private work is not only a heavy tax on the most robust constitution, but too often advantage is taken of his official position to cut down his fees or extort gratuitous advice.

It has been stated that in most districts the dispensary doctor would be better off if he got no salary but was paid ordinary mileage for the distance travelled in the discharge of his duties. Do you comprehend what this means? That the post-car owner is better paid at sixpence per mile than the man who, having acquired a learned profession, renders valuable services to the community?

I have said that when worn out with work, prematurely aged by narrow means and constant exposure, he cannot calculate on a pension.

It is true that the guardians have power to grant him, by way of superannuation, not more than two-thirds of his salary.

As, however, the entire pension must be paid out of the rates, the guardians rarely exercise this power, and that only in cases of extreme necessity, the old age dependent on the charity of relatives or friends, or of seeking the shelter of the workhouse, or of strug-

Dec. 16, 1903.

"The medical man who enters the Local Government Board's service as a union or dispensary medical officer does not do so from motives of charity, or with the object of contributing to a work of philanthropy by the gift of his time, his knowledge, and his work. He enters it in consideration of a salary and as a means of livelihood. His salary should be fair remuneration for the duties to be discharged, the responsibilities involved and the benefits accruing to the public. On the contrary, the salaries paid are totally inadequate. If it were not melancholy the contrast would be amusing. On the one hand men of experience, absolutely indispensable, and who could command their own terms, strenuously striving for most laborious, risky, and ill-requited work; on the other, boards of guardians, many of whom are not in the least educated, and who are not infrequently ignorant of the duties and responsibilities of their position, secure the services of officers, deeming they are conferring favours by their votes, and doubting whether the pitiables they offer are not too much."

The Local Government Board and the guardians are not to blame, it is their duty to appoint legally-qualified medical practitioners; in the name of common sense why should they pay those same legally-qualified practitioners sixpence more than to the services of the officials who, in the discharge of their duties, are less skilled than the medical officers who are their equals and get respectively twice their salaries, and who, in some cases, are in positions of great responsibility?

The blame rests entirely on the medical profession itself—doctors are indispensable; their services could not be done without for a single day; they have a monopoly, it is for them to fix the price of their work and they must be paid."

For my own part, I believe, and I expressed that conviction in the admirable report on the Irish dispensary system made by Sir William Thomson to the British Medical Journal, and published in 1892, that the real remedy for the unsatisfactory condition of the Poor Law Medical Service is to make it a part of the civil service, which should discharge all the civil medical duties of the country; in which the medical officers should be appointed by examination, receive adequate salaries, promotion and pensions, and should where it was possible devote their entire time to the treatment of the sick poor, prevention of disease, and the discharge of the other duties devolving on such a service.

At present, however, the moderate demands of the Poor-law medical officers hold the field.

Gentlemen, it largely depends on you whether these reasonable terms shall be granted. If you, the coming men, are wise, I say: if you realise that you cannot be done without, that you must be secured at any price, if you only appreciate your value, that in any other position you would be better off than in the Poor-law Service under the conditions which now obtain, and if you abstain from competing for vacancies, within a very short time it must be reorganised.

Bear in mind that reform of the Army Medical Service was not won by a general resigning, but by newly-qualified men refusing to fill vacancies. What your predecessors effected for the Army you can secure for the Irish Poor-law Service, to the lasting benefit of the public and of yourselves.

I feel bound to tell the teachers in other schools, to advise you not to enter the Poor-law Medical Service. Not only from a pecuniary but from a pro-
to some extent, the liability to congestive attacks. But the operation is often a failure. In enlargement due to irregular glandular over-growth, if palliative measures fail there is no alternative but removal. This can be effected either by inducing atrophy or by operating on the enlargement itself. The former method, having been doomed too much, is now falling into somewhat undeserved discredit. The fear of mental disturbances, and the strong sentimental objection to the operation, combined with the success attending the removal of enlargement, have caused the procedure to fall into the background. An enlargement can be removed through a perineal or a suprapubic opening. If the bladder is very small and rigid, and the prostate very hard and dense, the former incision is indicated. Under all other conditions the prostate is best approached through the bladder. The operation was performed by McGill fourteen years ago, and remains the same in all essential details. In 1892, Mr. Moulin pointed out that the whole vesical mass must be removed, and the exploration extended down the whole length of the prostatic urethra. This is the operation which is now generally performed. A certain amount of confusion has been caused by an erroneous description of what is called the capsule of the gland. But Shattock and Wallace have shown that the covering of the enucleated masses is a pathological product. Before performing the operation, if the muscular coating of the bladder has been ruined already by catheterisation and cystitis, the patient must be warned that the removal of the gland cannot restore it.

A CASE OF

PUERPERAL PHLEBITIS TREATED BY BEER-YEAST.

G. E., a married woman, age 34, was delivered of her second child after a protracted labour by the aid of the forceps. On the third day she complained of headache and general malaise, and in the course of the afternoon she had a slight rigor, when the temperature rose to 103° F. For some days the temperature rose daily to about the same extent, with the usual accompaniment of shivering and headache.

Exploration of the uterus failed to reveal any evidence of retained membrane, placenta or clots inside the uterus, and the organ was neither fixed nor painful. The uterine fluids were scanty but not offensive. Involution appeared to be following its usual course, although the lochia had ceased earlier than normal.

On the tenth day after delivery, the patient had a severe rigor in the afternoon, when the temperature rose to 106° F., and there was a less severe rigor later in the day. The rigors continued to occur once or twice every day, and were only slightly modified by the administration of antipyretics. In spite of these alarming symptoms the patient's general condition in the pyretic intervals was remarkably good. She took her food and slept well as a rule. She complained, however, of pain and a sensation of weight in the left calf, which was moderately swollen. The vein could be felt as an indurated cord in Scarpa’s triangle, where pressure caused pain.

This state of things continued for six weeks, when I was asked to see her. Her general state was fairly satisfactory, but there was a hectic
flush, and she was stated to have lost weight considerably during the last fortnight. The fundus uteri could be made out with some difficulty on deep palpation behind the pubes, the os uteri was properly contracted, only admitting the tip of the finger, and the uterus was movable. There was no vaginal discharge, and there had never been any fever, according to the nurse's account. No tenderness on abdominal palpation.

The patient complained of pain and stiffness in the calf of the left leg, which was slightly swollen and harder than the other. It was somewhat tender on pressure.

This state had persisted in spite of the administration of large doses of antipyrine and saline and the fact that she was on a diet, with only small quantities of food allowed. There was no evidence of consolidation or effusion in the-vesicles, associated with vaginal douches of one in a thousand perchloride of mercury. I advised a tentative injection of antistreptococcic serum, but this was objected to by the practitioner in attendance. As an alternative, I suggested the administration of beer-yeast in the form of a dry preparation known as leuvirine. A tablespoonful of the powder was given in milk four times a day. Within three days the maximum daily temperature had fallen to 103° F., and on the fourth day the afternoon temperature was only one degree above normal. During the next three days it remained normal. At this juncture the support of the nurse was withdrawn, and as the patient lived in a town many miles distant from London, the treatment was suspended for three days. Within fifteen hours of the cessation of the yeast the rigor recurred, and were repeated every day until the fresh supply arrived and the treatment could be resumed. Then the temperature again returned to normal, and in the course of a few days the patient was allowed to get up. The treatment was continued for ten days more in gradually diminished doses, by which time recovery was complete.

The interest of the case lies in the fact that the patient had been suffering from daily high temperatures for close upon six weeks, with severe rigors, associated with evidence of phlebitis of moderate intensity in the left leg. No treatment had any influence on the condition until leuvirine was administered, whereupon the temperature dropped.

That the effect was due to the treatment and not to any fortuitous coincidence may be inferred from the fact that on the treatment being temporarily suspended the fever returned, only to subside on resumption.

I may point out that the efficacy of beer-yeast in the treatment of streptococcal infections such as furunculosis and carbuncle is generally recognised, and it is surprising that its effects should not have been tried in other affections in which it is probable this organism plays a part.

**Special Articles.**

**BRITISH SANATORIA FOR CONSUMPTION.—XXIV.**

*[BY OUR SPECIAL MEDICAL COMMISSIONER.]*

**KELLING OPEN-AIR SANATORIUM, HOLT, NORFOLK.**

Among the various institutions seeking to provide efficient hygienic treatment for the consumptive poor, Kelling Open-air Sanatorium must be accorded a foremost place. Its establishment is in great measure due to the energy and ability of Dr. Burton-Fanning, of Norwich, and his cousin, Mr. W. J. Fanning, the originators of the now well-known Mundesley Sanatorium. But they have been enthusiastic. There are numerous influential Vice-Presidents, and a thoroughly representative Council directs affairs. Dr. Burton-Fanning is the Hon. consulting physician, and Mr. W. J. Fanning the resident medical officer. There are also medical referees in various districts. Mr. Edward Gurney Buxton is the honorary treasurer, and Dr. H. W. McConnel the honorary secretary.

The property has been generously bequeathed by a local friend, and is vested in trustees. A special building fund has been established. Certain beds are already endowed. Annual subscriptions, it is expected, will help towards general maintenance.

The weekly cost of each patient is reckoned at 3s. Only early cases, or those who are likely to receive definite advantage from a residence in the sanatorium, can be admitted. Each patient is expected to contribute according to his means. If a patient be unable to afford anything he may be admitted to a bed already paid for. A general rule provides that "no patient be admitted unless the money for his support be already in hand." In every case the cost of the patient must be arranged for either by the promise of a free nomination from a donor of a bed—or of money from the friends of the patient, or from the General Maintenance Fund. A subscription of £78 per annum entitles the subscriber to a nominal bed for a year; £2,500 will endow a bed permanently.

There is nothing particularly noteworthy about the site. The sanatorium is situated about a mile east of Holt and eight miles from Cromer. It is by no means extravagant, but is fairly protected. There are about thirty-five acres of ground. The original house, quaint and old fashioned, provides accommodation for the staff and nine patients. Ingeniously designed open-air pavilions are now in course of erection. A number of plain but excellent day shelters are at present in use. Those responsible for the conduct of this sanatorium have sought to secure the maximum of efficiency with the minimum of expense.

Mr. W. J. Fanning and the Building Committee have spent much time and thought in the designing of appropriate sleeping accommodation for comparatively poor patients. They have sought to obtain as near an approach to sleeping in the open air as possible, a facility of service, and therefore economy in maintenance; and saving in cost of construction.

We have carefully inspected the admirable bungalows and pavilions, the products of their scientifically directed experiments, and commend them to the serious consideration of all those responsible for the erection of institutions for the phthisical poor. At Kelling the irreducible minimum compatible with efficiency seems to have been attained. "The unit may be said to consist of a two-bedded cubicle. It measures 10 feet by 11 feet, and the height of the ceiling is 7 feet from the floor. Both above and below the ceiling there is ventilation for the roof and the upper part of the cubicle respectively. The double windows, 4 feet wide by 6 feet high, are horizontally divided at 4 feet 6 inches from the floor, the upper parts only being glazed. A wide three-foot eave protects the upper parts of the windows from rain and weather. Hinging cupboards and shelves are provided for the patients' clothes. There is five feet between the beds, four feet of which is occupied by window. The walls, ceiling, and partitions are varnished, and all external woodwork treated with tar-lime.** A building consisting of two sanatoria providing four beds, can be supplied ready for erection at a cost of £60.

The new pavilions, which at the time of our visit were nearing completion, are striking examples of what may be accomplished simply, cheaply and efficiently when directed by experience and judgment.
We were particularly glad to find that rational efforts were being made to encourage patients to continue some degree of work in the gardens or about the grounds.

The sexes are kept apart. A number of the women are dealt with in a house some distance from the sanatorium proper.

Careful notes are kept of every case. Much care is taken to ensure a good dietary. Large quantities of fats are given, chiefly in the form of butter; cod-liver oil is not generally administered, but little use is made of drugs.

The charts in general use have been excellently designed. The usual chart, in addition to the ordinary features, provides for the registration of expectoration, total gain in weight, rest in room and shelter, and exercise in walking or by working.

Considerable use is made of weekly average charts. On every hand there are evidences of energy, thoroughness, and good judgment.

The resident medical officer resides in his own house, which has been recently built and is in the sanatorium grounds.

Holst is easily reached from Norwich, and by arrangement a carriage meets any train.

Application forms, medical certificates, and all information respecting the admission of patients may be obtained from the Honorary Secretary, Dr. H. W. McConnell, Matlock Hall, Norwich.

University of Oxford.

An examination for a Radcliffe travelling fellowship, of the annual value of £200, and tenable for three years, will be held in Hilary term, 1904, commencing on Tuesday, March 1st. Candidates must have passed all the examinations required by the University for the degree of Bachelor of Arts and for the degree of Bachelor of Medicine. They must also have been placed in the first class in one, at least, of the public examinations of the University, or have obtained some prize or scholarship within the University unattached to any college or hall, and open to general competition among the members of the University. The successful candidate must before election declare that he intends to devote himself during the period of his tenure of the fellowship to the study of medical science and to travel abroad with a view to that study. The Regius professor of medicine and the examiners shall, two months before the expiration of the second year after the election of each fellow, present a report of the work done by him to the electors, who may, if they think the report unsatisfactory, declare the fellowship forfeited. The examination will occupy three days.

Papers will be set in physiology, pathology, and preventive medicine, and a subject will be proposed for an essay. There will also be a practical examination in pathology. Intending candidates should send their names, addresses, and qualifications to "The Radcliffe Examiners, University Museum," on or before Tuesday, February 9th, 1904.

Small-pox at Liverpool.

For the first time for 18 months the medical officer of health (Dr. E. W. Hope) was able to report to the city council that there was not a single case of small-pox remaining in any of the city hospitals. The epidemic had been on the decline for some months, and for the last four or five weeks only some half-dozen cases were in hospital until the last patient left on November 23rd. Scarlet fever, on the other hand, is prevalent, and there were no less than 391 cases under treatment in hospital on December 3rd. The general death-rate of the city for the past week was 22'2 per 1,000 of the inhabitants, as against 25'8 per 1,000 during the corresponding week of last year.

Cases of Peripheral Neuritis at Salford.

In connection with two cases of peripheral neuritis which occurred in Salford last week, Dr. Tattersall, the medical officer of health for the borough, has again the matter up and has had samples taken at the houses at which the two women purchased their beer and stout. These, on being carefully analysed, were found to be practically free from arsenic.
Mr. Maylard replied that it was more frequent now in Scotland than formerly, and the reason for considering that his case was of pyloric origin was the extreme regularity of the pyloric opening, and the fact that unlike other cases he thought people in good social position were more likely to give way to excesses in youth than in old age. He was not possible to obtain a reliable post-mortem examination.

Mr. Moylan, in replying, stated that he had been consulting the text of a book recently published in London and the cases operated upon by him to those about 25 per cent. As far as he could judge the cases were somewhat earlier in London. That much suffering was avoided by timely operation he was convinced.

ROYAL ACADEMY OF MEDICINE
SECTION OF PATHOLOGY
MEETING HELD THURSDAY, DECEMBER

The President, H. C. Earl, in the chair.

ETIOLOGY OF LEUKEMIA

Dr. T. G. Moorhead read a preliminary note on some investigations which he had been engaged in in the etiology of leukemia. He said that a number of extracts from glands obtained from a case of lymphatic leukemia had been made, and from all of these the injection of one of these extracts in the spleen of a normal animal produced severe changes in the bone marrow and of several groups of lymph nodes. The red blood corpuscles were also observed in the blood. Injections of a similar extract from normal human lymph nodes did not produce any change in the hemopoietic tissue. An extract from the morbid glands caused a fall in blood pressure, while the injection of extracts from normal glands had no such effect. He further noted that the morbid glands of the morbid glands contained some specific substance (not as yet identified) that might prove to be the cause of the disease.

Professor McWeeney asked whether Dr. Moorhead had used glands from myelogenous leukemia, and said that, inasmuch as the chemotactically active substance was different, owing to the difference in the chemotactically active substance, this was a matter of much importance. He said that the acidophils in the experimental animal required the presence of an acidophile with the object of nuclei. Classes of leucocytes were chemotactic, and he concluded by congratulating the author on his original and important contribution.

The Secretary (Professor W. Moorhead) said that the papers would probably be read at the next meeting, and Professor Scott joined in the discussion. He thought that the various forms of leukemia were all the same, but that the principle of cellular differentiation fairly extended from the one to the other very cellular condition, which were also associated with some common condition which might be of use for Dr. Moorhead.

Professor O'Sullivan believed that the papers would not account for the cellular leukemia. He hoped that the opportunity of these papers would be of use for Dr. Moorhead.

Drs. Travers Smith and Parsons, and the President
also spoke, and Dr. Moorhead replied.

DR. W. S. HAUGHTON showed tumour and section
removed from pectoral skin. This tumour clinically
resembled a simple inflammation, but under the micro-
scope revealed itself as sarcoma of deeper layers of skin,
containing giant-cells, small round cells and some
spindle-cells.

CANCER OF RECTUM.

Dr. HAUGHTON also showed a rectum, pelvic colon,
and part of iliac colon removed for carcinoma received
by the double method of laparotomy and pansacral
incision six weeks ago. Patient going on well. The
interest in the surgical method lay in the examination of
liver and pelvic and mesenteric glands before re-
moval, as well as mechanical points of technique, such
as arrest of hemorrhage from supra-hemorrhoidal
and middle sacral arteries and length of iliac meso-colon
for anastomosis to anus which was carried out. The
section showed well the structure of tumour to be a tyl-
pical adenocarcinoma of rectum extending around
the lumen of gut for more than three inches in length,
without infiltration of perirectal tissues or glands, a
point much to be appreciated by patient and surgeon.

ABSCESS OF THE BRAIN.

DR. ALFRED PARSONS showed specimens removed
from a man, 51, who was admitted to the Royal
City of Dublin Hospital on September 22nd, suffering
from Jacksonian epilepsy. The patient, who had been
previously in good health, with the exception of a
chronic cough, was suddenly seized with a convulsion,
and was carried into hospital during the attack. He
had in all some seven or eight attacks on the day of
admission. It was noticed that the lower half of the
left side of his face and the left arm from the elbow
down were paralysed. He had, however, no loss of
cower in his left leg, but the reflexes were exaggerated.
The paralysis gradually increased till he had com-
plete left hemiplegia with greatly increased deep reflexes.
He suffered also from violent paroxysms of coughing,
accompanied by the most forbid expecoration, which
poured out from mouth and nose. Physical examina-
tion revealed the presence of bronchietasis in the
lower lobe of the left lung. On September 29th, Mr.
Benson found the eyes perfectly normal, but three days
later detected the presence of definite double optic
neuritis. The headache became violent, the patient
shouting out, “Oh, my head, my head,” and saying
the pain was like a chisel going through the back of
his head. As there was no ear disease present, a
diagnosis of intracranial abscess near the Rolandic
area, secondary to chronic pulmonary suppuration,
was made, and Mr. Johnston was asked to trephine
the patient over the arm centre, and explore for an
abscess. This he did, but found no pus. At the
autopsy the left lung was found to consist of numerous
bronchietatic cavities filled with pus, and on examining the
brain after hardening, there was a large abscess filled with greenish pus lying
directly underneath the arm centre, not more than half
an inch from the cortex. The needle used in exploring
must have entered the abscess cavity, but before doing
had probably become plugged with brain tissue.

CANCER OF BREAST WITH SECONDARY GROWTHS IN
OVARIANS.

DR. J. T. WIGHAM showed a cancer of breast and
various internal organs secondarily affected, with sec-
tions. The cancer was of the ordinary type of scirrhus,
and was well marked, the interest in the case lying in the
route by which the disease had spread to the internal
organs. The breast was removed surgically, and some
months afterwards the patient showed signs of
secondary growths internally, and rapidly died.

As the post-mortem was not made until some three
months after the operation, the connection between
the breast and the pleura could not be established with
any certainty, but beyond that it was obvious that the
greater part of the internal organs affected had formed
secondary growths by direct continuity. Cancer
urethra, has never been removed in the way it will be. Partial removal of the prostate, performed now, was McGill's operation—and too dangerous to be a routine practice. It is justifiable in certain extreme cases.

Mr. P. J. Freyer, who exhibited specimens of an operation performed by him. He had removed entire in their cases the prostate, had much faith in vesicostomy, though it was a difficult operation. Any benefit among used lasting. Castration he had always seen from. He believed that both prostatectomy and vesicostomy were dead and buried—in this country.

Mr. Moulin had watched the progress which this operation had made up to his (Mr. Freyer's) operation. He was surprised that Mr. Moulin had gone to his (Mr. Freyer's) operation. He was aware that there was no such thing as a cure of cases of vesicostomy, but that was placed before the profession. In the last two and a half years. He attended by more completely successful operations, reducing the mortality, considering the age of the patients, was very small. It had not been observed in connection with prostatic enlargements. It had failed to regain the flow of natural micturition. It is absurd to refer to an operation as similar to his. No specimens of a prostate, resembling those exhibited, were placed in a museum before the date was placed before the profession. In Shattuck's view, the prostate was removed with the prostate. This question of merely academic interest, while attended with a small complete and permanent cure of all.

Mr. Herring said that the only treatment for this condition was interferent micturition. He did not agree with the markedly progressive, or that history necessarily follow the use of instruments. The symptoms do not arise from the contamination of the urine by microscopic organisms. If the symptoms are purely, if ever, increased by use of a sterile catheter. Mr. Herring: impossible for a patient to keep it clean. If properly taught, and the method of sterilisation of instruments is used, the patient is able to keep it clean. In cases already infected, it is necessary to use doses of micro-organisms as necessary. The repeated administration keeps up the inflammation, and this can be assisted materially in producing the symptoms which are so frequently seen.

Mr. J. G. Paroed considered very aged men with tolerant bladders the treatment of choice. At the expulsive power of the bladder, this after complete removal of the prostate where catheter life had lasted sixteen years. As regards age, Mr. Paroed believed that it was impossible. A proper class of those who have hard muscles for living, or are old and are able to procure assistance. Again, in those cases of prostatic enlargement, which do not appear to be due to aseptic catheterism. Operative cases might be classed as:—(1) Those of expediency and urgency. Cases of expediency are:—tively young men, with progressive enlargement of the prostate. In the majority of cases, these become complete; hemorrhage in and attacks of sepsis cause damage of operation in the two classepared.

Mr. P. L. Daniel said that obstruction as at present and not based on sound patho

classes can hardly be com-
d that the treatment of prosta-
resent carried out is unsound, pathology. Most symptoms
are due to secondary contamination by micro-organisms introduced from without. Symptoms due to prosta-
tatic disease per se are those of slight difficulty and frequency of micturition; all other symptoms being
due to cystitis, generally caused by dirty catheters, occasionally arising from the posterior urethritis, where micro-organisms have remained after an attack of gonorrhoea. Adenoma of the prostate differs from all other adenomatous growths in developing in the later years of life. Mr. Daniel pointed out that this growth probably arises from a pre-existent posterior urethritis. Treatment must therefore be directed first and foremost to the prevention of a posterior urethritis, or to its cure. Secondly, to the prevention of chronic cystitis caused by dirty instruments. An instrument invented by Mr. Herring renders catheterism practically safe. The use of such catheters in the early stage of prostatic difficulty will relieve the few symptoms really dependent on the prostatic condition, so that serious surgical interference will never be needed.

Dr. Horace Manders said that in his experience elderly men reduced to the constant use of the catheter do not show such universal tendency to skin and disseminated sepsis. He had found that certain drugs, like sulphonamide, help to prevent sepsis. He thought that male nurses ought to be more impressed with the importance of sterilisation, and he did not agree that sterilisation by boiling is essential. The careful and scientific use of the catheter has prolonged many valuable lives, but a large number of cases can be benefited only by a total removal of the prostate.

Mr. Mansell-Moulin replied on the whole discussion.

LIVERPOOL MEDICAL INSTITUTION.
MEETING HELD THURSDAY, DECEMBER 3RD, 1903.

W. Macfie Campbell, Esq., M.D., in the Chair.

Dr. F. W. Bailey read a note on the history of the stethoscope and showed an example of Laennec’s instrument.

Dr. K. Grossmann gave a communication on the occurrence of double focus in the human lens, as found by him in five patients during the last two years. The lens is divided by a sharp line into two areas of different refraction, in four out of the five cases symmetrical. The nature of this hitherto undescribed condition and the methods employed in examining it were described and illustrated by a number of diagrams and lantern slides; two of the patients were shown, a male, aged 20, and a female, aged 45.

Dr. Grossmann also demonstrated a patient in whose left eye the ocular conjunctiva was the seat of a number of large papillomata without any catarrhal or other discharge.

Mr. G. P. Newbolt read notes on osteotomy of the upper end of the femur, illustrating his remarks by lantern slides. He laid stress upon the following points — (1) All cases of marked tuberculous disease of the hip should be treated on an adductor frame in order to avoid the adductor deformity almost invariably present; (2) in all cases of bony ankylosis or of short, strong fibrous union with deformity, osteotomy of the upper end of the femur should be performed; (3) Acland’s operation of sawing through the neck of the femur, when present, is to be recommended; when absent, transstrochanteric osteotomy may be done. Gant’s operation, infratrochanteric osteotomy, is not so good, though it avoids sawing through a big mass of bone; (4) open incision with removal of the upper end of the bone is sometimes necessary, tenotomy or rupture of the adductors is often needed in addition. Septic sinuses about the hip offer no bar to osteotomy in their neighbourhood.

Dr. J. C. M. Given reported a case of byoscin poisoning.

Dr. Chas. A. Hill read a note upon enlargement of the thyroid at puberty. Two cases were narrated in which pressure symptoms arose. Both improved under the exhibition of thyroglobulin.
animals. The illness was no doubt angina.

Hr. Hoffmann raised the question of disease was not a septic process. Mastitis was in causal relationship known; the same was true of many as erythema and purpura. Some taken for granted.

Hr. Mosse said that many cases of ran their course with the same kind of

German law courts as interesting A man was accused of having an and infecting her, knowing that he was at the time suffering from a contagious disorder — namely, syphilis and gonorrhoea. The woman contracted the disease, and was taken to hospital, where it was said she would take five years to get her cured, as tertaries had already appeared. The judgment given was to the effect that whoever, knowing that he is suffering from a contagious disorder, has sexual intercourse, giving the disease to the other party, is guilty of the offence of infecting bodily injury according to § 230 of the Legal Punishment Book. The culprit in this case was convicted, and sentenced to five months' imprisonment. Serve him right!

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 12th, 1903.

ALCOHOLIC NEURITIS.

At the Gesellschaft der Aerzte, Zappert showed a young girl, aged 44, with alcoholic neuritis. According to the history the child was fairly healthy up to the middle of last year, although there must have been a certain amount of rachitis present. About the end of July last year the child was running about and was happy, when quite suddenly, and without anything to account for the change, it became weak and languid, till finally it could not walk. After this, the arms became weak, accompanied with pain on movement, as well as in the legs. About the end of August a careful examination of the cerebral nerves, fundus of the eye, intelligence, power of speech, &c., was made without discovering any deviation from the normal. The weakness in the extremities was not confined to particular groups as might have been expected. Neither were there atrophy, tremor, nor ataxia in arms or legs. Tendon reflex was absent in both arms and legs, and Romberg's symptom undoubtedly present. One very peculiar symptom of pain at the roots of the nerves and along the muscles of the paretic extremities was present, which gave rise to more than a clue to the alcoholic nature of the case. This pain was more pronounced in the region of the arms.

On closer inquiry it was discovered that the child had been prescribed half a litre of beer every night, which had been faithfully administered since the previous Christmas, with the result described.

By perfect abstinence and free use of the faradic current the whole morbid picture soon disappeared, although the unsteady gait and patellar reflex still exist.

PRESSURE IN RIGHT AURICLE.

Gaertner then gave a long description of his experiments on the pressure in the right auricle of man. If the arm be raised high above the head, which will produce anaemia, and the tonometer applied to the finger, it will be found that the instrument will show the disappearance of the anemic state, and give an arterial pressure in the capillaries corresponding to the motive force. In a great number of the experiments, however, this form of estimating the auricular pressure is not quite accurate owing to the length of the arm, which exhausts a quantity of the motive force in resistance or in driving the blood forward. This difference of level in measuring the blood pressure is no innovation, as it has long been practised in measuring the venous resistance. The arteries, however, are not comparable, as the contractile wall of the artery may destroy a large amount of the cardiac force before the haemastic wave reaches the instrument. An example will show this difference at once. If a leg or arm be raised to the level of the third or fifth rib it will be found equal to
secured in the wound, the upper to the upper angle, and the ileum. A gauze plug was also placed in brought out by the side of the ileum that the complication of this large of which was unexpected before a case a difficult one to treat. The was so extensive that no surgeon, excision under ordinary circumst treatment would have been a 3 between the ileum and the asew was decided to do this at a later. It was quite evident that excision of that she could endure at that of he thought, was interesting, as its malignant disease in that part of the extent of sloughing of an intestinal wall, which could take or general evidence of its occur it was situated beyond the point therefore, not subjected to press bowel, had, he said, much to do with events.

CHELSEA HOSPITAL F
ABDOMINAL HYSTERECTOMY

ARTHUR GILES operated on a a patient of Dr. Gordon Hall. S she had been curetted for dystrorrhagia, with temporary im present time she complained of m iliatic region, weight in the lower and troublesome frequency of m found that she had a fibroid tum a tumour was felt occupying and pelvis; it appeared to be about Examination with the sound the cavity was deflected to the rig peared to occupy the left corna of the body of the uterus downw It was evidently of such a size a true pelvis in such a way as to caus Operation was therefore advised by the patient, on the ground that she was incapacitated duties. On opening the abd found to be held down by the pres sure; when it was raised the tumour was found arising at fundus on the left side; the left from the tumour. The broad in such a way as to leave the behind, whilst the situation necessitated their removal uterine arteries were clamped tumour removed about the left lower part of the uterus being wedge. This gave good ant over the stump. A forceps vical canal to facilitate drain had been tied the peritoneal tother over the stump in abdominal wound was closed it said that the indications for c sure of the tumour and the dis The tumour being subperitoneal uterine cavity, there had been tion. The tumour was a solid a median origin over the fun the left cornu and the attach tube, it would have been a vectomy, but as it was, thi The position of the tumour
LEADING ARTICLES.

Dr. Battle said that, in cases of the malignant disease, the proper anastomosis of the colon, and it was if possible, as the bowel was all important part of the operation. The case, he advised, was a very difficult one, and there was no doubt that the operation was more successful than usual. The cases in which hysterectomy was easiest were those in which the body of the uterus was involved, for then the tumour enlarged and rose into the abdomen it stretched the cervix in such a way that the field of operation became readily accessible. In a case such as this the manipulation required in dealing with the stump had to be carried out on the floor of the pelvis, in much the same way as if the operator had to deal with a normal uterus. It was, perhaps, not generally realized that the removal of a very large tumour was really an easier matter than the removal of a uterus of the normal size. He pointed out that if the uterus was cut out wedge-wise from the cervix the flaps could be approximated much more readily than if it were cut straight across.

The further carrying out of this principle in such a way as to remove nearly all the core of the cervix constituted Mr. Bland-Sutton’s method of panhysterectomy.

The patient made an uninterrupted recovery.

DR. WOMEN.

For Myoma.—Dr. R. A. woman, aged 30, five years previously from menstrual troubles and myomectomy. Dr. Hull noted: On examination of the uterus, pressing it, the size of a cocoa-nut showed that the uterine was displaced. The tumour appeared from performing her abdomen the tumour was the pelvis by atmospheric up out of the pelvis the almost entirely from the left tube appeared to arise and ligaments were divided the right ovary and tube division of the left appendages with the tumour. The papillated, and the uterus and level of the internal, the ring cut out in the form of an anterior and posterior flaps was passed down the cervix, and after the vessels were tied the edges were brought together in the usual way. The abdomen closed in three layers. Dr. Giles for operating were; the cerebral disability produced thereby, eutaneous and not involving the ad been no excess of menstruation a solitary one, and if it had been he fundus instead of implicating attachment of the left Fallopian seen a very suitable case for myomectomy, this was out of the question, uterine made the operation more difficult than usual.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 16, 1903.

ST. BARTHOLOMEW’S HOSPITAL.

The principles involved in the various proposals to reconstruct the ancient hospital of St. Bartholomew’s are of such importance as to demand the most vigilant scrutiny and consideration. Those principles do not merely concern the interests of a famous medical charity, but on their proper definition will also largely depend the future policy of such institutions in all parts of the United Kingdom. The Mansion House Committee appointed to consider alternative reconstruction schemes issued a report, published in our issue of December 9th. That document has received little public commendation on the one hand, while on the other it has been met with a continued and ever-growing chorus of criticism. One of the main contentions against the Mansion House Committee Report—namely, that it was opposed by the Medical Council of the Hospital—has been finally settled by the production of a Council Report unanimously in favour of a
Mr. Herbert Spencer

Almost the last of that noted band of men in the nineteenth century, undertook to make a new law, not only of biology, but also of things entire," has left us. Dr. Tyndall, Spencer, all are gone, and of the association with the early promulgation of evolution none still remain, with the exception of Mr. Russell Wallace. Not that it is pretended that the doctrine of evolution in new, in one form or other it appears in philosophy of note from Thales down. On the one hand, Mr. Spencer's application to the widest spheres possible—biology, psychology, ethics—and, on the other, the doctrine of natural selection. It is often true that Spencer's work is merely the extension of the fields of the laws Darwin found to hold domain, but nothing can be further from the truth. Not only in its inception but in its present form Spencer's earlier work is prior to Darwin's "Principles of Biology," appeared some time ago, the "Origin of Species." In his subject he was still more in his standpoint, Mr. Spencer from the other champions of evolution mentioned. They were all primarily, and merely, men of science. Mr. Spencer was science at all, but a philosopher. He had a wide knowledge for his domain, and science was of many fields of interest for him. It is perhaps at any rate this is not the place to appreciate his contributions to the sum of knowledge, but there is grave reason to doubt whether he grasped its real problems. He dealt with connected laws holding sway in knowledge, but not with questions of the conditions of its possessor, his intellect, which, in spite of all obstacles, he finished the gigantic undertaking set itself at his own expense, issued work after work, publishers and the public alike refused to accept his contributions, and five-and-twenty years ago his thought dominated the speculation of the world. The completion of his system of synthetic philosophy, he set the arena of letters, but many will respect (whether they agree or not with his conclusions) the courage and the brave protest against England's attitude towards the South African Republics. For many years a martyr to chronic dyspepsia, and it is said that he has left an autobiography in which his life has been recorded in considerable detail. By the
the general theme men who exercise heroically good nure ready to others, there is the men unfitted for us, This received the those who hold arrangements for daily exer-

His great scheme he seldom entered I remember with him or not his attitude toward many years he was it is said that he his sufferings are. By the death of Mr. Herbert Spencer the world has lost one of those intellectual giants the influence of whose life work is destined to sway the destinies of mankind for all succeeding time.

Notes on Current Topics.

The Prevention of Consumption in Cork.

The Cork branch of the National Association for the Prevention of Tuberculosis is to be congratulated on the energy it has shown in promoting the establishment of a local sanatorium. The branch has, as one may judge from the Cork Press, not only roused a great deal of public interest in the proposed scheme, but has gained the sympathetic attention of the various local boards with whom the responsibility lies of taking measures for the health of the community, as well as of caring for the poor in their respective jurisdictions. The County Council and the Cork Rural District Council have, we understand, expressed their willingness to co-operate in the maintenance of a sanatorium, but for some hidden reason the Cork Corporation has not yet taken any step. A suitable site has been offered in the neighbourhood of Cork by Mr. Barter, the proprietor of the St. Anne's Hydro, at Blarney, a gentleman of public spirit—but the offer must be given a definite answer in the course of the next few weeks. Under the circumstances, it is to be hoped that no time will be lost, but that the various public bodies concerned will proceed to action with all speed. The Local Government Board has intimated that money may be borrowed from the Board of Works at the low rate of three and a half per cent., so that little courage is needed to go on with the scheme.

Compulsory Tooth Extraction in a School.

A curious case has recently been heard before the Yorkshire Nisi Prius Court by Mr. Justice Grantham. It seems that the Vicar of Helmsley, in his zeal for the welfare of the children in the village school, secured the services of a dentist, who came and inspected the mouths of the scholars. One of the latter, a girl, thirteen years of age, was placed in a chair, and, in spite of vigorous struggles and remonstrances, a tooth was extracted. Other evidence showed that the tooth in question had been previously prepared for "filling," and that both the gum and the cheek were injured. The parents of the child not unnaturally entered a strong protest against their child having been submitted to an operation of the kind without their consent. A local newspaper the Malton Gazette, commenting adversely upon the incident, spoke of the dentist concerned, a Mr. Recordon, of York, as a "tool of the vicar," the Rev. C. N. Gray. The name of the dentist was not mentioned in the newspaper notice, but Mr. Recordon brought an action for libel, and was awarded £250 damages. Candidly speaking, it is not altogether easy to understand the grounds on which Mr. Justice Grantham charged the jury. "Because a child behaved stupidly," he said, "and cried and went away with her hands to her mouth these aspersions
the filaria into the human subject. Mosquito, and, more recently, D. a former pupil, had shown the as sleeping sickness and a variety. Moreover, the latter organism had found in the blood of a patient with bite from a species of tsetse fly i germ of sleeping sickness, symptomatic patient ultimately developed and died. This latter discovery, made placed beyond doubt the causal co-trypanosoma with the disease. Like many others, was sorely in its he it was hoped that Sir Francis Lov with as much success on his second did on the first. Sir William Cl and Sir Frederick Young second thanks to Sir Patrick Manson for address, after which the hospital were open for inspection by visit

The Value of "First Aid"

It is customary for ambulance a lecturers to cite instances of accident might have been readily averted by of a little simple amateur surgeon perhaps, of a policeman who in bleeding to death from a stab in the who saves her life by twisting a bit the upper arm. If they roamed tilted over, however, it would be hard to illustrate than that reported recent village in Kincardineshire. While young farm servant accidentally b which bled so profusely that he died The accident is a curious one, as the great difficulty in staying the hem a severed tongue. Perhaps one of arteries were partially severed, or the man belonged to that class of persons profusely and dangerously from the In any case, anyone possessed of amount of "first aid" knowledge contrived to apply pressure to until competent medical assistan It is hard to imagine any bitten w tongue that could not be stitched arrest hemorrhage with the aid of needle and sewing cotton. In the "bleeder," medical science has now certain means of checking the hæmorrhage use of a drug that represents one brilliant of modern therapeutic disco

Medicinal Men and Marriage.

If statistics are to be believed the average
marriage age of members of the medical profession
has, during the past few generations, grown later
and later. The usual explanation is that the condi-
tions of existence render competent professional
income every year more difficult of attainment.
In Paris, however, medical men appear, willy-nilly,
to be looked upon as prizes in the matrimonial
market. According to the French correspondent
of the evergreen Referees an inquiry into the
attractive journalistic inquiry, "What is woman's
favourite profession for a man?" has called forth.
a most unexpected answer. Prima facie one
might have supposed that lovely woman would
have chosen the law, or the church, or the Army,
or the Navy, or literature, or art, or one or
other of the somewhat motley group of callings
that are usually included under the elastic title of
"professions." But no, we learn that when put to
the vote by a well-known French lady's paper
neither the scientist, the banker, the musician, nor
the explorer had a single vote, but the favourite of
all, by an enormous majority, was the doctor! The
soldier came next, then, in order, the sailor, the
engineer, and, lagging far behind, the literary man.

The "Tabloid"
The important action by
Burroughs, 4Wellcome and Co.
Thompson and Capper, homoeopathic chemists, of Manchester, Liverpool and elsewhere, was concluded by judgment delivered on Monday last, December 14th. The trial occupied the attention of Mr. Justice Byrne's court for seven days. The issue arose out of an action by Messrs. Burroughs Wellcome and Co. to restrain the defendants from supplying goods other than those of plaintiffs when "Tabloid" was specified in orders or in prescriptions. The defendants replied by an action to remove the marks "Tabloid" and "Tabloids" from the register. Mr. Justice Byrne decided in favour of the plaintiffs on all counts.

Obituary.

Mr. McLEOD of HAW

With much regret we announce
McLeod, of Hawick, on December
and painful illness.
Mr. McLeod took the L.R.C.S.
long ago as 1849, and soon after
the district of Hawick, where at the tu
was by far the oldest practitioner.
It is interesting to note that his fir
thither was an outbreak of chole
Mr. McLeod, who was widely and un
died in his 77th year, and leaves be
as well as a son and a daughter.

Medical News

Catholic University School of Medicine

On Saturday evening the fou
of the students of the Cathol
MEDICAL NEWS.

The arrangements are complete for the Belfast Annual Medical Dinner to be held on the 1st of December, at the Royal Hotel. The dinner will be followed by a meeting at the Hotel, when the following resolutions will be thrashed out:

1. That the Belfast Medical School is inadequate to the needs of the city.

2. That the Belfast Medical School should be amalgamated with the University of Dublin.

3. That the Belfast Medical School should be endowed with a fund of £10,000.

The meeting will be presided over by Sir John Dillon, M.P., and will be attended by many of the most prominent medical men of the country.

Ireland Medical School was held. Sir Christopher Nixon presided. Mr. John Dillon, M.P., in proposing the health of the Medical School and its professors, said he found that in the various schools of Dublin and Belfast in the year 1902 the Catholic University School of Medicine registered 72 students, Trinity College, Dublin, 45; the College of Surgeons, 35 and Queen's College, Belfast, 55. He then proceeded to refer at length to the University question. What he looked forward to was a university that would be characteristic of Ireland in its democracy, in its freedom to all the people, in its devotion to science, for which the Irish people had always been celebrated, which would be a great scientific institution, and would be characteristic of Ireland in regard to unity within its walls, devotion to science in the broad and most unfettered freedom, combined with that devotion to the spiritual life which had been equally characteristic of Ireland. Sir Christopher Nixon, in replying, hoped the United Irish party would make the settlement of the University question the front platform in its propaganda. Professor MacWeeny proposed the health of the past and present students. Dr. Cox and Mr. Boyd Barrett responded. The Chairman proposed the toast of "Our Visitors." Very Rev. Dr. Mannix, President of Maynooth College, in replying, called attention to the report of the Royal Commission, which, if acted upon, would leave Ireland without university education. Mr. T. L. O'Shaugnessy, C.R., in responding, said he hoped whatever was right, and whatever was just, and whatever produced equality in Ireland would be done. The toast of "The Chairman" concluded the proceedings.

Consulting Surgeon to Jervis Street Hospital.

At the meeting of the Managing Committee of this hospital on the 10th inst, it was moved by George C. Stapleton, Esq., seconded by Wm. Anderson, Esq., J.P., "That in consideration of Dr. Austin Meldon's unflagging services to the hospital the committee appoint him Honorary Consulting Surgeon to the hospital." The medical staff had previously unanimously adopted the following resolution: -- "That we, the medical staff, unanimously recommend the Managing Committee to appoint as consulting surgeon Dr. Austin Meldon, D.L., who was for so many years a member of the staff of the hospital." Dr. Meldon has been connected with Jervis Street Hospital for many years, for thirty-three of which he filled the post of visiting surgeon. The Managing Committee, in thus recognising his long services to the hospital, have conferred on him the highest honour in their power, and one which its recipient has well merited.

Extension of the Metropolitan Asylums Board's Ambulance Service.

The Metropolitan Asylums Board on November 28th decided to extend the operation of its ambulance service so as to include the transport of medical, surgical, and mental cases for which application might from time to time be made by any authority or person with the Metropolis. Such extension shall not be held to include the removal of cases of street accident or of patients to and from the several lunatic asylums under the control of the London County Council, unless by special sanction of the ambulance committee, or, on emergency, of the chairman of that Council or the clerk to the board. It was also decided that upon the necessary legal authority being obtained for the mangers from the Local Government Board the work should be immediately undertaken and a charge of 7. 6d. made in respect of each removal, and in addition a mileage of 10. 6d. beyond the boundary of the metropolis.

The Recent Attempted Murder of a Medical Man at Fir Vale.

Mr. Justice Darling has tried and sentenced the man accused of the attempted murder of Mr. George Whittenbury White, at the Fir Vale Workhouse Infirmary, Sheffield. On the conviction of the prisoner by a jury of attempt to murder, the learned judge sentenced him to penal servitude for life. The punishment thus rapidly meted out seems somewhat unduly severe, notwithstanding the seriousness of the crime.
FORTY YEARS OF PROFESSIONAL LIFE

By THOMAS RICHMOND, L.R.C.P.,
L.F.P.S.Glas.

If any apology be required for detailing recollections of a professional life extending over a period of forty years, it may be found in the fact that these recollections embrace as they did the ever-memorable years of Lord Lister, then Professor of Surgery in the University, and Surgeon to the Royal Infirmary, laying the foundations of the antiseptic system of surgery. His attention was first directed to the problem of hospital gangrene and pyemia at a time when there had been an outbreak of hospital gangrene in one of the best equipped hospitals in the country. After this he left London for Edinburgh, where he became house surgeon to the late Mr. Sydenham's daughter. He married a few years later.

In 1860 he was appointed to the Chair of Surgery in Glasgow University, as successor to Dr. Lawrie. I have vivid memories of those mornings in the Royal Infirmary, when he would visit the bedside of a patient upon whom he had performed an operation. His was the most painstaking manner of working, spending considerable time in observing the patient's movements and responses to treatment. He was a man of few words, but always the smile of recognition, and to his students was a most considerate teacher. He had charge of No. 25 Ward, on the first floor, as well as the old building. In 1864 Lister commenced experiments in the Glasgow Royal Infirmary, which led to such brilliant results. It was then (1867) before he gave the world the antiseptic system of surgery, and following the issue of the Glasgow Medical Journal and the British Medical Journal, I am indebted to Dr. Edington for articles on the subject. As a result, I was able to introduce the antiseptic system of surgery in Glasgow, and during the next few years, these efforts were all in vain.

of his knowledge. This was
ration. Though he did what
in Glasgow to combat de-
s were all in vain till Pasteur's
researches opened a new way—not the exclusion of
oxygen, which was hopeless, but combating the
microbes."

As colleagues, Lister had in the Royal Infirmary
Emeritus Professor George Buchanan, the late Dr.
James Morton, and Dr. William Lyne on the surgical
side; and on the medical side the much revered Sir
William Gairdner, the late Professor Leishman, and the
late Dr. Scott Orr. Among his colleagues several were
opposed to his methods, and constantly compared
results in the wards with those of Lister. All the
same, pyaemia and hospital gangrene continued to
prevail—diseases that are seldom seen at the present
day. It was no uncommon experience in those days
for students to make their visit to the Infirmary, and
not a ward in which they had been a day or two
closed, and all the patients removed to other wards on
account of a death from pyaemia. From an article on
"Hospitals" in one of the new volumes of the recently
issued "Encyclopedia Britannica" I quote the
following:—"Listerism means devoted and con-
tinuous attention to the details of cleanliness, and its
effect is well illustrated by the fact that the adoption
of the aseptic or Listerian treatment of wounds had
reduced to 4.3 per cent. in 1880, in Germany, a morta-
tality of 41.6 per cent. in 1868, and a mortality in 1872,
according to Sir John Ericsson, of 37.8 per cent. in
the larger metropolitan hospitals, and of 25.7 per cent.
in University College Hospital. According to Schade's
Antiseptic Statistics, that has been further reduced to
2.9 per cent. in all uncomplicated amputations for
disease or injury, and is still failing. With the
enormous saving of life following such marvelous
results, as indicated in the quotation I have just made,
is it to be wondered at that Lord Lister should have
had honours showered upon him from many countries
of the world, and well may he be styled the "grand old
man of surgery"?

During my student days, sanitary science was in its
infancy. Sir W. T. Gairdner was the first medical
officer of health in Glasgow, with the late Dr. James
Dunlop, who was police surgeon for the Southern
district of the city. The Sanitary Chambers were then
situated in a large shop in College Street, and the
Sanitary staff consisted of Drs. Gairdner and Dunlop,
with Mr. George McKay as sanitary inspector, and who
at present is chief sanitary inspector in Perth. I am
obliged to Dr. Chalmers, medical officer of health, for
the following particulars regarding the sanitary staff
at present under his control. The indoor clerical staff
consists of thirty members. There are seven district
inspectors, twenty-six nuisance inspectors, fifteen
epidemic inspectors, six female inspectors, six night
inspectors of ticketed houses, and a few subordinates;
and this list is exclusive of the chiefs of various de-
partments. From an address delivered by Dr. J. B.
Russell, when a presentation was made to him from
the sanitary staff, on the occasion of his appointment
as medical member of the Local Government Board for
Scotland, I quote the following, which indicates some
of the difficulties under which the sanitary staff
laboured in those early days of its existence. He says:
"Those were the days when the master of works and
to some strange place, but I shall content myself with the austere example of his inebriates. I am shown to have experienced great changes at home, and have brought up to such suffering. I shall never forget the appearance which came to my house one summer morning just as we had been drinking. He prevented him going out. However, he managed clothes, and how he did it, I cannot tell, but there was a cap, trousers, and jacket on, with a mind to what was "vice-versa," where is the place of his son. This quotation on the subject I contributed to The Times January, 1901. After 1901, for criminal inebriates, a class of non-criminal drink were provision has yet been long to this class with the restraint could they be proportioned of such cases be for a considerable the retreat in the immediate vicinity, to which medical patients without delay, a situation would be on a grade of the poor as theession, in dealing with a seriously handicapped subject on the short period of three weeks—where the case and in one instance where the case taken place. Experience weeks' treatment in the effects temporary improvement unsatisfactory. We have undergone the short period of a week or two of the supplicant, were staggering about the district. A lengthened period of these cases is, being so, some plan might be utilised. The literary man his pen, the artist his pencil, this way the labour of the put to a profitable use, and largely if not altogether so ago a rich woman was on the London magistrate for the…... The magistrate stated the inebriate home he was unable to die. Again, a lady sought several thousand pounds from her husband. Within seven days for drunkenness. So easily be multiplied, and the need urgent for the establishment of a new class of inebriate. There appears to be in this a need to engage the serious attention of the same time leaving plenty of room for private enterprise, which would be the humane end of a drunkard from an undutifully the result. Perhaps I may crave you to make a few of which have been made in the case of those years of which I have

your indulgence to take a s of the numerous advances in medicine and surgery during have been reminiscent. The
triumphs of surgery have been very remarkable indeed. The wildest flight of imagination could never in my student days have thought for a moment of such daring and brilliant work as that executed on the brain and spinal cord by Sir Victor Horsley and our own townsman, Sir William McEwan, whose of- wonde-er osteotomies it may truly and literally be said that "the crooked are made straight." Could even the most optimistic among us in the forty days have dreamt of a brilliant surgeon like Sir Frederick Treves having such a wonderful succession of recoveries in operating in cases of appendicitis? Compound fractures in my early days went often disastrously wrong; now they are no special source of anxiety to the surgeon. The surgeon may even step in now, and at least relieve the worn-out old man, weary of life, suffering from enlarged prostate, by the operation of enucleation. The Roentgen rays have come to the rescue of the surgeon in many ways, as, for instance, in locating exactly the position of a splinter or needle embedded somewhere in the flesh. In the field of therapeutics much ex-

cellent work has been done. Rheumatism many years ago was an unsatisfactory disease to treat; now we can at least give speedy relief to the intense pain in acute cases by means of the salicylate. Temperature can be lowered quickly and pain relieved speedily by means of pheneicin, antipyrin, and such-like. Nitrite of amyl very soon relieves the agony in angina pectoris. The father of Dr. Weir Mitchell pointed out the resemblance between the symptoms of poisoning by snake venom and febrile fevers, and the further research on the subject by Professor Fraser, of Edinburgh, and others has led to the treatment of various diseases, including diphtheria, by means of antitoxic sera. About the year 1873 Sir Lauder Brunton experimented in cases of diabetes with raw organs. Some years later Brown-Séquard proposed testicular juice as a general tonic, and later still came the treatment of tuberculous glands, first advocated by Dr. Murray, of Newcastle, and others. In obstet-

rics much progress has been made, and our own Professor Murdoch Cameron has made a very useful contribution in this important department by his series of successful Caesarean operations.

In medicine proper, along with pathology, much real and substantial progress has been made during the period we are speaking of. Our knowledge of nervous diseases is now much more accurate. We have the localisation of function of the various parts of the brain and spinal cord, and our knowledge of diseases produced by micro-organisms is constantly extending, and with that knowledge a more satisfactory way treating diseases is a method less empirical and much more rational. We have just to think for a moment of the research work of Pasteur, of the investigations of Koch into tuberculosis, and the valuable work of many others engaged in research, to realise the immense value to humanity at large of the investigation into the hidden things of Nature by men who devote their lives to such self-sacrificing work. I cannot close this hasty sketch without mentioning the name of Major Ronald Ross, who has, along with others, by his investigations in connection with that great scourge, malaria, been the means already of saving the lives of millions of human beings. Among the names of those who will be handed down to posterity most surely there will be those of Lister and Ross as real benefactors of the human race. In conclusion, gentlemen, a certain writer has said that "Man is not pre-ordained to be the victim of sin and corruption, but to be made happy through his perfections. If he firmly wills it, he can attain this perfection in all its relations of life. He may know beforehand that, when he feels sorrow and is in nothing in himself which is not as it ought to be. The sorrow and suffering are, in themselves his certain guides to happiness." That, gentlemen, is the material out fabric with which we, as medical men, are called upon to deal, and the responsibility is ours to endeavour to the very best of our ability to help to put right that "something in himself which is not as it ought to be." I would say that genius and talent always count for something, but even to the average man who
Further thought and former cases occurred was in perfect health, surgical and nursing uly little discharge f were so regularly empl tract, and especially th in a surgically clean co found that the widely-s were very common amo the uterine discharges where the patient's cleanness, in fact, was its absence. In short, discharge from the uter have been torn, as on wounds bathed with this will separately heal. It case of a surgical asept no assistance in keeping but would devote all her together in order to rej had caused.

It therefore seemed the method of preventing im incised cervical lips was from the other whilst the I first attempted to effect passed through the tip o higher up on the anterior being passed through the p vaginal wall, so that when drag apart. But, after softened, the lips fell toget ordinary manner; and so in some years practised, the simple, surgical, and was effective.

I had not previously been done by anyone else, but I years at The Hospital for that it has proved equally s

The patient being anesthet position, the vagina is wi The posterior wall of the weighted speculum, a double anterior lip of the ov, and ... sounds up to No. 16 or 16½ is then passed half-way up the say, in many of these cases to three-quarters of an inch that extent on each side; the anterior lip is drawn for needle threaded with strong g left side of the anterior lip close incision, and then across and point on the right side. The short, and a similar stitch between the former and the anterior lip is sponged clean upper, and then the lower, of course, is that the anterior drawn together—the raw su pletely; whilst the posterior Two or three wool plugs are th the cervix to check hemorrh in about sixteen hours, and the posterior lip is glazed over wi In about a week, it is covered extending up to the angle of the catgut in the anterior lip and, as a general rule, the wound the same time it is becoming g membrane. At the end of te stitches and remove them, as flattens out and lies nearly in with this difference—that both being covered with mucous a adhere together; and on pass that the cervix is widely paten
to find that the discharge, and at the end of a fortnight the patient is able to resume her home life.

For the purposes of this paper, I have looked up my notes of all the hospital and private cases I could remember for whom I have performed this operation. They amount altogether to eighty-seven cases. In every case my notes show that the first period after the operation was practically free from pain. In twenty-eight of the cases, I have a note of the patient at the end of two years, and in every one of these cases the relief had been permanent for that time. In another thirty-three cases, my notes only extend to an average of eleven months after operation, and in each of these the relief was equally definite. Of the remaining cases, in ten I can only find a note for three or four months after the operation, but in those again the relief so far had been permanent. In eight cases, varying from four months to two years, some amount of menstrual pain had returned, but in each case to a much less degree than had been formerly experienced. In the remaining eight cases, I have no note after the first month; but, as I have asked every patient for whom I have done this operation to write to me if she had any return of her previous symptoms, and as I have not heard at all from these eight cases, I think I am almost justified in thinking that they have also been permanently relieved; and that therefore I am well within the mark in estimating that of the patients with dysmenorrhoea from conical cervix for whom I have performed this operation, in 91 per cent. the relief from pain has been complete and permanent.

With regard to sterility, I find that out of the eighty-seven cases forty-one were sterile, having been married for periods varying from two to eleven years. I have heard, so far, from twenty-four of these cases, in eighteen of whom pregnancy has resulted after an average sterility of five and a half years. On the whole, therefore, I think I am justified in saying that, in these cases with conical cervix, both the dysmenorrhoea and the sterility are directly due to the contraction and lengthening of the cervical canal, and consequently to mechanical obstruction; that the latter can be completely removed by incision of the cervix, provided that the incision can be kept permanently patent; and that, by the method I have described, which, I submit, is surgically sound, such patience can be secured; and finally, that the actual results in practice are sufficiently good to warrant a more extended trial of the operation.

REPORTS ON A

DUCT CANCER IN ISOLATED

AXILLARY GLAND,

AND OTHER CASES. (a)

By H. MACNAUGHTON-JONES, M.D.

In the final report on the case of isolated duct carcinoma in the axillary gland, a section of the growth was shown with the epidiastroscope. The report was furnished by Dr. Cuthbert Lockyer, Previous sections had not exhibited any malignant characteristics. The breast was then cut into several sections, and from these six different portions were examined, with the following further results:— (1) Some of the ducts are atrophied, and their epithelium is shrunken and degenerated. (2) There are numerous small cysts, produced by involution changes in the ducts. Some of these are filled with epithelial débris. (3) Fibrous processes lined by epithelium project into some of the above cysts. None of them are branched, but they constitute an early stage of intractable papillomata. (4) The epithelium in some of the dilated ducts has proliferated and is arranged in layers, several coils in thickness. This indicates an early carcinomatous change, and accounts for the secondary deposit of cancer found in the enlarged left axillary gland.

Dr. Macnaughton-Jones said that this explained what otherwise would have been a pathological mystery. It also proved that superficial examinations of

cess emphysemas of the up to cause prominence of condition, does not lead to the skin, and can readily
the anterior wall emphysem is generally asso
 discharge (which can be lide meatus), and does not the cheek. The diagnosis

can always be cleared up by puncturing the antrum, preferably through the nose, and washing out the cavity. Transillumination will not be of much assistance in the differential diagnosis. The real difficulty in these cases of malignant disease of the superior maxilla is not so much in diagnosis as in prognosis, that is, in deciding whether an operation holds out good prospects of a cure. This is best settled by carefully investigating the amount of extension of the growth. Given that the general condition of the patient does not contra-indicate operation, it may be said in general terms that success can hardly be expected in cases where (a) the skin of the cheek is much affected; (b) the glands of the neck are enlarged; or (c) there is extension backwards into the naso-pharynx. Also, if there is extension above the zygoma the operation is one of greater severity. In the case before us, the skin of the cheek is infiltrated, and there is some extension above the zygoma. There is, however, no extension into the naso-pharynx into the mouth or into the nose (the outer wall is merely pushed inwards without fungation). The glands of the neck are not enlarged and the patient is in good condition to stand an operation which the extension above the zygoma suggests will be a severe one. There is one point more to consider. In the case before us there is undoubtedly implication of the orbital plate of the maxilla. It will be necessary to remove the orbit plate, and this, by depriving the eye of support, may lead to downward displacement of the eye, with at least diplopia and possibly ulceration and disorganisation.

A week later the superior maxilla was excised, the growth being apparently entirely removed. There was a certain amount of extension under the skin of the cheek and behind the external angular process, but it was found possible to make a clean sweep of it. The orbital plate was removed.

After the operation, the patient had an uninterrupted convalescence. From the first she had no difficulty in taking fluid nourishment, and readily assisted by frequently irrigating the cavity. The superficial and deep parts of the wound healed aseptically, and since the operation the patient has had no pain to speak of. It has been found necessary, however, to remove the left eye, which became ulcerated three weeks after the operation.

BRITISH SANATORIA FOR CONSUMPTION.—XXV.

[BY OUR OWN MEDICAL COMMISSIONER.]

NORDRACH-UPON-MENDIP SANATORIUM.

Through the enterprise and far-seeing wisdom of Dr. Rowland Thurnam Nordrach-upon-Mendip was opened as a sanatorium for phthisical cases in the beginning of 1899, and at a time, it is well to remember, when but little was known in this country of the details of open-air treatment and the systematic conduct of a thoroughly hygienic management of consumption, such as that conducted by Dr. Otto Walther at Nordrach in the Black Forest.

The charms of the Mendips have been made known to many through the delicate and delightful stories of Somersetshire life by Mrs. Walter Raymond, but it is mostly due to Dr. Thurnam that their reputation has been established as a very desirable health station.

The Mendip Hills, consisting chiefly of limestone and sandstone, form a somewhat isolated but elevated and picturesque moorland. The country is somewhat undulating; there are copses of beech and firs, and the hills present striking gaps or clefts, and from the high ground extensive views, rich in many charms, are obtained.

The district presents plentiful opportunities for health-giving exercises, the air is invigorating, and the country is calculated to exercise a beneficial psychological effect on many minds.

The sanatorium originally consisted of a house which
much frequented by visitors who appreciate a
cuisine, and the attention ensured by the presence
the proprietors on the premises. A few hundred
the town is the Hôtel Bein-Séjour, the popu-
nearer of which has necessitated extensive addi-
tion in course of erection. It is admirably situa-
ted at the angle of the circuitous road
commands a full view of the splendid panorama of
town and harbour. To complete the list of
hotels should be made of the Hôtel Oriental and the
Hotel.

The great thing in choosing rooms is to secu-
sunny aspect. It is often worth while to put up ir
town on arrival in order to make sure of obtain-
s suitable apartments at Mustapha, and in such case
traveller cannot do better than go to the Hôtel
Régence, which commands a view of the Place 
République, close to the quays. It is centrally situ-
ed and comfortable, and the prices are a good deal
than in Mustapha.

The season nominally begins at the end of Oct
but the rush does not, as a rule, take place until a
the middle of December. In my next communi-
I propose to dwell more particularly on the ther-
peutical aspects of the climate of Algiers, the joy
hither being an indispensable preliminary to
consideration.

Transactions of Societies.

BRITISH GYNAECOLOGICAL SOCIETY.
MEETING HELD THURSDAY, DECEMBER 10TH, 19

DR. HEYWOOD SMITH, President, in the Ch

EXHIBITS.

DR. MACNAUGHTON-JONES showed the modifi-
of Bossi’s dilator, by Tress, comparing it with t
strument he had exhibited a few years since in
Society, and pointing out its lightness, greater e
application, &c. Having reported on and use
dilator for the first time in this country, he was a
apologise for exhibiting this improvement on th
he had then shown. The lacerations of the o
recorded by some authorities abroad could no
thing were due to too rapid dilatation and
employment of the dilator in unsuitable cases.

DR. MACNAUGHTON-JONES, jan., said that h
used this improved form of Bossi’s instrumen
tertipara in whom it had been necessary to
 premature labour between the seventh and
month, on account of a large fibroid. The di
difficulty in securing sufficient dilatation for th
As he was able to pass his finger easily into
he introduced the instrument with the caps on,
spent half an hour in dilating the cervix. The
ition was performed at seven o’clock, and th
was born at eleven. No laceration occurred.

DR. G. R. HODGSON pointed out that lacer-
cervix was especially likely to happen w
amount of fibrous tissue in the part had been in
by processes of chronic inflammation. Under
situations the laceration was not to be attr
any fault inherent in the instrument.

DR. MACNAUGHTON-JONES exhibited with the
scope sections of isolated duct cancer in an
 gland, and other cases, which will be found on
889.

DR. G. R. HODGSON remarked that the co
arcotic ovaries was always thickened. Tho
thickening must in the first instance arise fr
 gestion, it was remarkable that the congesti
not always followed by cirrhosis. This mig
to the fact that in some instances the capsule
ovary gave to the increased blood pressure, o
others it did not do so. The question, theref
whether, when great suffering resulted from a
ovaries incision of the capsule might not rel
distress.

DR. J. J. MACAN said that several spec
diseased ovaries had lately been exhibited
appreciate a good Society, which had been attended with very similar clinical symptoms, and which closely resembled one another in appearance, but some had been described as cirrhotic and others as sclerotic. Unless there was an essential difference between the two conditions which it was desirable to emphasize, it seemed to him that it would be better, especially in regard to the reports of the proceedings, to use one term rather than two. He believed that every abnormal increase in the fibrous tissue of an internal origin was liable to be followed by contraction.

Dr. MacNaughton-Jones said that the different specimens which he had seen sections by the epidiascope were clear views, not taken from what he regarded as true "cirrhotic" ovaries. In the latter there was distinct concretion of the capsule and cicatrization with shrinking of the tunica and connective tissue in the stroma, with obliteration of the follicles. Occasionally there were small pus cavities. Of course, such hardening of the ovary involved the process of sclerosis. In the sections shown by him the ovaries were rather hypertrophied than reduced in size, but there was a process of sclerosis proceeding throughout the stroma, and involving all the structures from the capsule inward. The practical point was that such ovaries caused great suffering, and, clinically, were often regarded as free from disease.

The President said that the question was one that might well be discussed at some future meeting, as it was desirable to have a clearer understanding upon it.

Dr. Bedford Fenwick showed his specimen and remarked—the specimen which I now show is, in several respects, of much practical interest. It consists of a uterus containing fibroid growths, three of which have projected into its cavity. I showed it last Tuesday at the Hospital for Women, Soho Square, from a patient, aged 50, married at twenty-two, who has had eight children, the last having been born eight years ago. The catamenia began at the age of twelve; since she was thirty years of age the losses have been more profuse; for the last six years she has noticed an increasing swelling of the abdomen. She was told that she had a tumour, but that this would get quite well and disappear at the change of life. For the last four years the swelling has much increased, and the losses have been extreme, at times exhausting her completely. But still the same cheerful and hopeful account was given to her. For the last two years she has had almost constant loss, and for the last few months great increasing abdominal pain. Finally, having arrived at the age of fifty, and finding her hopes of cure still deferred, she came to the hospital, and was immediately ordered into the wards. The uterus was enlarged nearly to the level of the umbilicus, with outgrowths filling the pelvis. It was nodular and apparently fixed. She was very blanched, her heart's action quick and irritable; she was extremely wasted, and seemed, in fact, to be in the last stage of exhaustion. Her first cardiac sound at the apex was fairly good—clear and distinct—and I therefore determined to operate.

Incidentally, I should be glad if this opportunity to say that I am largely guided now in the performance of any abdominal operation for the removal of a tumour by the conditions of the first heart sound, for this simple reason, that when it is clear and sharp there is rarely much, if any, fatty degeneration of the ventricular wall, and, as I have on several occasions pointed out, it is that particular degeneration of the heart which is most often associated with long-standing abdominal tumours which cause the sudden death known to occur in these cases, and which brings about the collapse of the patient after laparotomy has been performed. That this is a good practical working rule I think I am entitled to claim, because during the last nineteen months I have not lost a single case after an abdominal operation, either in hospital or private practice.

Returning to this patient: on opening the abdomen, I found the uterus fixed in the pelvis, densely adherent behind to coils of intestine; with this large cystic
Dec. 23, 1903.

Lips of the cervix, which at first, an inch long, gradually contracted months later, he had frequently felt as an ordinary cervical lip, but with pain. The explanation of this was obvious, inasmuch as the blood was materially interfered with by condition. Finally, he ventured to the advantages of the operation he had simplicity and its success. It took to perform, and then the patient till the tenth day, when the stitches. On the other hand, the relief from pain cases, and the cure of the ster per cent, were results which, so far treatment of the kind had obtained he could at least plead that it like success.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.
MEETING HELD DECEMBER 4

DR. SEYMOUR TAYLOR, the President

Mr. F. G. LLOYD read a paper on APPENDICITIS.
The anatomy of the appendix was fully discussed, as the different varieties of the malady their differential diagnosis, were fully dealing with the treatment of the of expressed a leaning towards conservative the conditions calling for surgical inter with the methods of procedure which most useful. A series of cases which the author's observation with the conclusion drawn from a study of the various conclusions the paper. The discussion was postponed to a future meeting of the Society.

A paper on BOLDNESS IN THE TREATMENT OF HEART FAILURE was read by Dr. ALEXANDER MORISON, which attention was specially directed to instances of grave cardiac failure occurring in adults or in those in the prime of life, was no evidence of vascular degeneration of reserve force was commensurate with it. In these, the tincture of digitalis bined tinctures of digitalis and strophanthidin recommended in doses of 15, 20, 25, or 30 intervals of four hours, until a definite produced upon the action, force and capacity and failing heart. This might require administration of the drug until 200 or 300 grains have been taken. Before beginning this method, however, it was necessary to prepare certain particulars for the action of the surcharged venous system should suitcases by venesection (which referred to leeching) to four or five ounces, limbs drained by Southey's tubes or by fluid effusion in chest or abdomen made possible. It was admitted that this method by reason of the closeness of the supervision necessary was more adapted than private practice, but with the assistance of nurses these difficulties might be overcome by a method efficiently carried out in the home. That there was a certain element of rapidity in obtaining cardiac control admitted, but provided that only suitable selected, and sufficient skilled supervision were exercised, this risk was by no means over, the only alternative was in the major to stand aside and watch the patient slowly die, or to play with remedies in an irrational manner, and in the famous he

is fully detailed and the assessed. The symptoms malady, together with the are fully described. In the affection Mr. Lloyd observed, and stated as interference, together which he had found which had come under the conclusions to be presented conditions and discussion on this paper was the Society.

OF HEART DISEASE

MORISON. The cases to y directed were those of type occurring in young of life, in whom there degenerations and whose ated with their development of digitalis, or the combined croup, were 20, 24, or 30 minutes at a definite effect was prond capacity of the dilated it require the continuous tit 1500 or 30 minutes had this method of treatment, to prepare the patient in action of the remedy. m should be relieved in i (which the author pre ena, the anasaraous tubes or by incision, and lumen removed as far as that this method of treatment was adapted to hospital the assistance of good at he overcome and the put in the patient's own tain element of risk in this cardiac control was also o only suitable cases were ed supervision and control by no means great. More as in the majority of cases patient slowly or suddenly lies in an inspective and the fatuous hope that the light, in some inexplicable a course which was neither sowing in the educated

Nauheim, expressed agree ment with the views of the author of this paper as they were in accord with his own observation and experience. At the same time he deprecated the use of digitalis and its congeners in cases in which the action of the drug was not called for. A careful consideration of the conditions of the individual case was important in all instances of disorder of the heart, and this held good not only in the matter of medicines, but in the matter of reference to physical therapeutics. The use of the carbonic acid bath was an instance in point, and harm might easily be done to patients who were not carefully watched. He attached great importance to sparing the heart, and was in the habit of interposing after the second, third, or fourth day of bathing a bath-free day. Dr. Lilienstein also referred to the importance of mechanical treatment of heart cases (such as massage and active and passive gymnastics) which had at Bad Nauheim been developed into a perfect system in connection with the baths. He agreed with Dr. Morison's remarks as to the value of blood-letting in suitable cases, and had seen good results in many instances, especially in cases of aortic disease with raised blood pressure.

The President considered that the tendency of modern medicine in the treatment of cardiac failure was summed up in the word boldness. The Nauheim bath, the graduated exercise, the increasing muscular efforts, all introduced within recent years, pointed to the same conclusion. Probably had those methods of treatment which had been so ably advocated by Dr. Morison been suggested in the immediately preceding of practitioners they would have been received with opposition, if not with ridicule. But modern clinical experience was altering our views of treatment. In the great majority of cases of heart failure not only was there a want of balance between the two sides, or between two cavities of the heart, but there were results of this, and so far as he was able to read the phenomena of heart failure, congestions of various organs and parts constituted, in great measure, the enemy which had to be attacked. Therefore he resorted to venesection in many instances, and to leeching frequently, but trusted more to the former than to the latter method. Nor did he overlook the advantage which sleep afforded in these cases, and frequently prescribed opium or morphia, providing the kidneys were free from organic disease. There was, however, no "golden rule" in the treatment of such cases, and the peculiarities and idiosyncrasies of the individual had to be taken into account as well as the visceral malady in formulating any line of treatment.

Mr. R. W. Lloyd, referring to an allusion to the work of the anaesthetist in Dr. Morison's paper, pointed out that there were differences between the methods of the physician and the anaesthetist in the matter of heart control. One of the forms of treatment was associated with the administration of drugs in liquid form to cases of heart disease accompanied by loss of control, while the latter administered a drug in the form of vapour, very gradually, continuously watching its effect and being ready and able to vary the amount given or withdraw it entirely on the appearance of signs of any loss of control of the heart.

Dr. Nevill Wood agreed with Dr. Morison that in a limited number of cases large doses of digitalis after suitable preparation of the patient would produce results that might be described as startling, but in another class of cases equally extraordinary results could be obtained by the use of almost infinitesimal doses. He, therefore, preferred to advocate precision rather than boldness in cardiac therapeutics.

Mr. W. P. Mallam quoted a case of aortic regurgitation accompanied by extreme cardiac pain and distress in which complete relief followed blood letting to the extent of eight ounces. So much was the patient impressed by the efficacy of the treatment that on a subsequent occasion he begged for a repetition of the venesection.

Dr. Alexander Morison, in his reply, reiterated the necessity for careful selection of cases for submission to the rapid method of controlling the heart, but said that these would be found to be of frequent occurrence in subjects under forty. He also explained his preference for venesection over leeching, as a preparatory or therapeutic measure, on account of its more sudden or rapid
Used as compresses, the inflammation diminishes well as the itching. When, however, the eczema is a complication, this latter should be treated. In pityriasis of the scalp, the former is indicated along with the general internal treat

**Syphilis.**

The treatment of syphilis has undergone no change in the last few years. The use of mercury or iodide of potassium, and frequent injection, has been abandoned for the use of the hypodermic syringe, to the benefit of the patient and the chemist. The method now employed in the secondary stage of the disease, consisting in daily injections of soluble salts. Some employ weekly injections, others daily injections. The advantage of the latter is well recognized. Of the injection, says Peyronneau, the best is that of mercury alone, in doses of 0.0001 gram per day, and continued daily for a month; it is then repeated. The four centigrammes by injection; this salt is one of the best for this purpose. The binicotine of mercury is excellent, and for various reasons, it is impossible for the patient to come every day to the consultations in such cases. The weekly injections of ca substitute.

**Appendicitis.**

Professor Robin believes that appendicitis is very frequent and that medical treatment is not always successful. According to hyperasthenic dyspepsia, the greater number of cases of appendicitis is accompanied by constipation and cecal pain. In the beginning, appendicitis would then react upon the mucous membrane of the affected portion of the intestine, and it is advisable to prescribe Castor oil or calomel followed by irritates intestine should be prescribed, while the the cæcum might be treated by mercury or calomel followed by irritates intestine should be prescribed, while the cæcum might be treated by mercury. The use of a diphtheric ointment or injections of morphia.

If this treatment is carried out with care, says M. Robin, surgical interference will be unnecessary.

---

**Germany.**

*From our own Correspondent.*

Breslau, December

On the 25th ult. a discussion took place at the Society on Dr. Abel's paper on the vaginal route in gynaecological cases. Dr. Bröse declared himself an adherent of the vaginal route since 1894, and had had a death in six cases. In spite of the classical ovariotomy still held its place, ovarian tumours were better removed by this method. In cases of malignant ovarian tumours, the above was decidedly the better. In my opinion there are limits beyond which the end cannot be attained from the vagina.
In retroflexion he had seen good results from the Adams-Alexander operation. Vaginal celiotomy was of great value in extra-uterine gravidity, in cases not too far advanced in pelvic abscesses and bilateral tumours of the adnexa. The statistics in comparing the results after the two operations were not in place, as only the severe cases were reserved for the upper route.

Hr. Th. Landau pointed out that vaginal celiotomy could never replace laparotomy, which came into consideration only in diseases of the female genital organs and it was not adequate where there were complications with the veriform appendix, intestines, uterus, &c.

If a tumour was thus walled, it could be removed per vaginam regardless of size, of thickness of walls, or adhesion, and if there was danger that its contents might escape into the peritoneal cavity during the extraction, abdominal section was indicated. In ectopic gestation, on account of complete toilette, the upper way should usually be preferred. In the case of inflammatory tumours the vaginal route had its limits.

Hr. Koblanc was of opinion that improvement in the technique of laparotomy had led many who at one time had adopted the vaginal route to return to the former. In any case a careful diagnosis should be made beforehand, and if complications were present, the upper route should be selected.

Hr. Schaefer considered Pfannenstiel and Hestner's suprasymphysary section to be a decided advance, as air did not get to the intestines, ruptures were avoided, and a scarcely visible cicatrix resulted.

Hr. Mullerheim considers malignant degeneration of myomata to be very rare, and myomata should only be operated on when there was much hemorrhage, pressure on neighbouring organs, in pain, or if rapid growth was noticed.

Hr. Duhlens believed that all gynecological tumours could be removed per vaginam; nevertheless laparotomy could not be dispensed with. It would be used in about 25 per cent. of the operative cases.

In case of need, if when the vaginal operation had been commenced it was seen that it would not serve, the wound could be simply closed and the mass attacked from above. Myomata should only be operated on when they caused distress, but patients who had them and went to a gynecologist always had distress. He thought enucleation was the most dangerous of all myomata operations, as great cavities were left in the uterine walls. These should be drained, and the peritoneum carefully closed over them.

Hr. Abel, in reply, said that the vaginal route must still be the one of choice. If a malignant tumour was found, the opening made below should be closed and the operation carried out from above. The danger of hemorrhage rendered this indispensable. The use of laparotomy should be much restricted.

At the sitting of December 2nd, Hr. Grawitz showed a man, set. 41, a lead-worker, who had peculiar muscular contractions. The twitchings were such that only a few bundles of muscles contracted at one time (paroxysmal twichings), and that the contractions gradually passed off. Electrical excitability was intact; further faradic current [slightly exaggerated. Sensibility was normal, the reflexes were in part heightened; walking was rendered difficult, and also the use of the hands. The disease was very rare, and had been called myoarthryia. It was a pure neurosis that did not lead to degeneration in the cord. The prognosis was unfavourable, or, at least, uncertain.

Hr. Gutmann showed a child, set. 14, with Tuberculosis of the Conjunctiv.

On the left lower eyelid was an ulcer, and around it yellow nodules. There were also diseased glands in...

and under treatment for a week or two before pro-
ceeding to operative measures. After three weeks’
treatment, the patient getting no better, Mr. JESSETT
decided to operate. There was complete absence
jaundice, and plenty of
The diagnosis arrived at was that she had gall-stones,
probably one of which was encysted. At the opera-
tion a very free incision was made about two fingers’
breadth below the margin of the false ribs, extending
from the middle line downwards and outwards for a
distance of about six inches. On exploring the gall-
bladder it was found to be considerably
A sandbag was now placed under the patient’s body;
this had the effect of bringing the liver and gall-bladder
very much more prominently into view. Some gauze
was packed round the gall-bladder, and a free incision
made into the exposed part. A considerable quantity
of brownish tenacious fluid escaped, and the gall-bladder
itself was wiped carefully off a piece of gauze.
On introducing the finger, gall-stones were at once
apparent. By means of the scoop fourteen of these
stones of considerable size were removed. On ex-
amining the duct leading from the gall-bladder to the
common duct another stone was felt impacted. A
needle was passed into it with the hope of being able
to break it up and push it back into the gall-bladder.
This being found impossible the lower end of the duct
was drawn out through the wound, and an assistant
holding this firmly out and upwards, a very good view
of the duct was obtained. An incision was made over
the stone with a narrow bistoury, and the calculus
removed. A few catgut sutures were introduced to
close the incision into the duct, and the liver was
allowed to drop back into its place. A drainage-tube
was introduced into the gall bladder and conveyed out
through the parietal wound; this last was closed by
three layers of sutures, the opening in the gall-bladder
being fixed to the wound. Mr. JESSETT said the interest
of the case was the ill-defined character of the symptoms
existing in a very fat woman, and, further, the
method of withdrawing the liver itself through the
opening in the abdominal parietes enabling the surgeon
to have a thoroughly good view of the gall-duets, and
so enabling him to remove a calculus which was
encysted in the bile-duct without any great difficulty.

The patient made a very good recovery.

Royal College of Surgeons of Edinburgh.

At a meeting of the College held on December 15th,
the following candidates, having passed the requisite
examinations, were admitted Fellows of the College:—
Sydney Herbert Allen, L.R.C.S.E., Melbourne, Aus-
tralia; Arthur Alison Bradburne, L.R.C.S.E., Buxton,
Arthur-Bernard Cridland, M.R.C.S.Eng., L.R.C.P. Lond,
Wolverhampton; Daniel Randolph Gonsalves, L.
R.C.S.E., Ootacamund, India; William Colin Mac-
kenzie, M.D., B.S., Melbourne; John Macmillan,
M.B., C.M., D.Sc., F.R.C.P.E., Edinburgh; James
Hutcheson, Postell, L.R.C.S.E., Victoria, Australia;
Richard Staward, L.R.C.S.E., Springfield, Glasgow;
and Harry Findlater Wilkin, L.R.C.S.E., Wickham-
brook, near Newmarket. At the same meeting Dr.
Peter Hume Maclaren and Dr. James Ritchie were
elected representatives of the College on the Board of
the Royal Infirmary for the ensuing year; and Mr.
Henry Wade, M.B., F.R.C.S.E., was elected Consul-
vor of the Museum.

Society of Apothecaries of London.

The following candidates having passed the neces-
sary examination have received the diploma of the
Society, entitling them to practise medicine, surgery,
and midwifery:—A. E. Bird, W. H. Bush, E. M. Cox,
G. C. M. Davies, A. H. Falkner, H. J. Gater, C. R-
Hannon, W. Lovell, S. Northwood, F. Robinson,
S. H. Ryan, L. C. A. Savatard, and D. A. Stepney.
On the other hand, it induces premature scientific publication of views and theories, not only hampers true scientific workers, but baseless hopes of alleviation in the minds of sufferers, to be replaced later by bitter appointment. In the investigation of the of cancer there has, of course, been a great of misapplied ingenuity. There is hark article of food, for instance, which has not time or other fallen under the ban of some or less acute theoriser. A recent exam this is the silly article by a medical man current number of the Empire Review, in it is maintained that the alleged increase of in Ireland is due to the consumption of bacon. It is very doubtful whether there considerable increase of the disease in and as the writer does not bring forward but assumptions and dogmatic statements in favour of his thesis, it occurs to us that the whole theory is merely an argument in of protection against imported meat. rate, since he believes the same causes cancer and physical deterioration, his may be neglected, for, whatever may be in England, there is certainly no physical generacy among the peasantry of Ireland come back to more serious investigators, seems to be just now a tendency to turn away the parasitic theory, and to examine more what may best be called predisposing conditions. Cancer presents so many analogies with the discovery twenty years a specific cause for the one at once held out similar success in the case of the other organisms—bacteria, protozoa, yeasts—has maintained at different times as cause disease, but it may now be said definitely specific parasite of cancer has yet been est It is natural that investigation along these having failed, attention should now be directed towards the other factors which are concerned in the production of cancer. Using the intrinsic causes, Mr. Morris draws in particular to two main theories, that of and that of Cohnheim. The former that the beginning of neoplastic growth a loss of balance between epithelial and c tissue elements. This theory in itself cient, since it would rather explain epithelial increase than a local growth however, in conjunction with the hypothesis local irritation as a necessary condition, covers most of the facts. Mr. Morris, is rather in favour of Cohnheim's doctrine "tumour germ," as explaining best the facts, and, at the same time, giving further inquiry. This theory, as stated by him, is that the point of origin of all neop group of cells of embryonic nature, which are either those "which preserve in organisms their embryonic anatomical or which have acquired them again weakening of their chemical and ph activity." Like Thiersch's, this hyp not complete in itself, but requires the

Mr. Morris draws attention n theories, that of Thiersch m. The former suggests neoepithelial growth is due to en epithelial and connective theory in itself is insufi
rather explain a general an a local growth; taken, ion with the hypothesis of neoplastic condition, the theory acts. Mr. Morris, however, f Cohheim's doctrine of a explaining best the known same time, giving light for theory, as stated by Durante, origin of all neoplasms is a chronic nature. These cells which preserve in the adult chronic anatomical characters, quired them again through chemical and physiological hierisch's, this hypothesis is if, but requires the assumption of some exciting cause to rouse the "tumour germ" to active growth. Apart from either of these theories there are, of course, many other lines of inquiry being followed up. The question of the role of the blood supply in the distribution of metastases requires much further study, though it has long been a subject of observation. On the other hand, the relation of new growths to nerve supply has received far less attention than it deserves, and Mr. Lenthal Cheattle's recent investigations show a remarkable definiteness of relation between nerve areas and the incidence of rodent ulcer. The only conclusion to be drawn from the present state of our knowledge of cancer is that, although we see no immediate prospect of discovery of its cause, yet every new fact throws some light forward, and at no time were so many new facts being discovered.

MATERNITY CONFERENCES.

The causes and prevention of infantile mortality is a subject which has received, not before it was time, much attention of late from medical men and others who are interested in those vital matters which directly influence the physical prosperity of the human race. The lamentable ignorance of the most elementary facts about the rearing of children, and, in many cases, the almost complete indifference affected by parents towards the health of their offspring, are only too evident when mothers of the poorer class come with their infants to the out-patient departments of hospitals and dispensaries for advice, which is often but imperfectly understood and perfunctorily carried out. The English nation is not the only one whose vitality is thus menaced, for it has been recently stated that in France a very high pro
portion of infants are annually sacrificed in this manner. A contemporary affirms that, with a view of combating the frightful ignorance there met with, the Prefect of the Seine has established in each of the twenty arrondissements of Paris a system of "conferences in maternity," intended for the benefit of women of the working classes whereby they can receive suitable instruction in the rearing and feeding of infants. Many well-known physicians and scientists have promised to co-operate with the local authorities in the teaching arrangements necessary for the carrying out of the scheme. It would be well if a similar plan could be adopted in this country, especially in our great cities, where the evils resulting from want of knowledge are most prevalent. There are already signs that the various municipal bodies and corporations are alive to this worm at the root of our physical prosperity, and it is not unreasonable to suppose that if they were approached in the right way they would give all the encouragement in their power to an enterprise which could not but react favourably upon the social life and vitality of the nation. The details of organisation required to set the movement upon a sound basis need, of course, the most careful consideration, for, above all things, such lectures and demonstrations as are proposed

Vegetarianism in Infancy.

From the anatomical point of view it has been abundantly proved that a mixed diet is one best adapted to the organs and processes of digestion and absorption of the human race. No one will deny that there are times when it may be advisable to abstain from flesh foods, and many dyspeptics are benefited by eschewing nitrogenous foods of animal origin, but to be permanently deprived thereof seems an unnecessary form of asceticism which is devoid of any sound physiological basis. We have no wish to enter into a controversy regarding the “pros” and “cons” of vegetarianism beyond the simple statement that, as a system, it does not seem applicable to the needs of human life. The address recently delivered before the Childhood Society by Mr. A. B. Kingsford, in which he stated that attempts to rear children successfully upon a purely vegetable diet were doomed to failure, has already evoked numerous comments in the daily Press from devotees of the vegetarian cult. It stands to reason that the growing frame of a young infant requires animal fats and proteins which can only be supplied with difficulty from the vegetable kingdom. Could we but see pure milk and fat properly administered to the tender nursing instead of the pernicious farinaceous substitutes with which they are only too often fed, we should probably be able to eliminate rickets from our midst. As Mr. Kingsford very rightly pointed out to his audience, there is nothing which can really take the place of the child’s natural food, but, failing that, recourse must be had to a pure artificial pabulum which shall contain the needful proximate principles, and this can only be obtained from the animal world. A certain proportion of vegetable food enters into the diet at a somewhat later stage of the child’s existence.

The Hygiene of the Handkerchief.

The proper business of a convention of the National Women’s Christian Temperance Union, held a few weeks ago at Cincinnati, was entirely upset by a sudden and unexpected debate on the hygiene of the handkerchief. It appears that on one of the speakers being welcomed with the customary flutter of handkerchiefs, a very practical delegate, Miss Brehm, of Illinois, there and then proposed a resolution directing the delegates present to keep their handkerchiefs in their pockets, except when in necessary use. She backed up her resolution by the argument that the wide distribution of colds she noticed among those present could be easily accounted for by the prevalence of such an unhygienic habit. Her proposition seems to have caused a considerable sensation, and roused much opposition, but nevertheless, was carried by a large majority. Seriously, the handkerchief, when used as freely as it is in America for other than its proper purpose, is a grave sanitary danger. There is no doubt that most nasal catarrhs are of infective origin, and it is contrary to all principles of asepsis to allow germs of disease, when they have been incubated.
but several further important points have also come under the scope of the present investigation, namely, the veracity of the reports of the Roumanian custom officers that it cannot evade its obligations with the other countries into which it is bound. Another important piece of information is that rats on board ship are being affected with cholera, and that the most important conclusion drawn from this is the unanimous recommendation of the national Sanitary Office of Paris, to which office all reports of cases should be sent by the customs officials of the various countries. The office would provide impartial information on the state of cholera in the least possible time, and would, it is hoped, take the necessary action to prevent the disease from spreading.

The Dangers of Sewage Consumption

While fully appreciating the importance and sense of responsibility of the various bodies and their officers of recent years in helping to prevent the spread of cholera, it is not enough that all should remain content with the present state of matters. The problem of ensuring the purity of the streets and the general public health is a matter of urgent necessity, and it is to be hoped that the proposals for the regular examination of sewage samples will be taken up with the utmost seriousness. The samples mentioned in the report of the Hackney Sanitary Committee have been taken from the barrows of the street-hands, and have been examined bacteriologically. It is found that of seventeen samples sewage was found, some of which contained traces of cholera. The samples came from separated sources, Surrey, West End, and some from the streets of London. It is evident that the sewage is not being properly dealt with. The question of the disposal of sewage is one of the greatest importance, and it is to be hoped that the authorities will take it seriously.

the greater watchful lity displayed by local cent years, one cannot amount of work there in hand. Nor can all utely by them. The themselves, and till they go of articles of food ground for a criminal alway remain a care that will take its e and suffering. It is that it should be possible mon watercress in the r. King Warry's recent nitary Committee. Dr. 1 to suspect watercress upt in his district, as aters suffered 4,6 times aters. Taking samples street-hawkers he had logically. In every one sewage-organisms were ame from five widely be, West Ham, Spital Jarden, and Shoreditch. Warry examined himself, y were found " to be fed age." Ought it not to condign punishment the he tradesmen concerned rh our contemporary the cleansing such cress with danger whatever can be remove much of the filth, but it has never yet been credited with germicidal properties, and till it has these in a marked degree it will be well not to partake of watercress, washed or unwashed, that has been reared in a bath of alvine dejections.

Euthanasia.
To nearly every physician there occasionally comes the question in the treatment of some painful and incurable disease—why prolong the suffering? Is it right or kind by artificial means to try to keep the patient alive when each added moment is only an added pang to bear? Would it not be better by cessation of active treatment and application of gentle narcotics to allow the sufferer to slip quietly, easily, and quickly out of the world? The physician has to decide such questions for himself with his own conscience, and he does not usually make any one the wiser for his decision. Some excitement, however, has recently been caused in New York by a clergyman, the Rev. Mr. Wright, publicly urging the propriety of euthanasia in case of persons afflicted with incurable disease. He safeguarded his proposals by various conditions, e.g., the consent of the patient and his family, and the decision of a jury of parsons and doctors. It is probable that Mr. Wright is surprised at the indignation his suggestion has stirred up, for in many civilised and uncivilised communities what he suggests takes place as a matter of course. The ancient Greeks, for example, with that rigorous application of reason which characterised their attitude in relation to all the affairs of life, thought suicide not only justifiable, but even a matter of duty. It is true, however, that the general feeling of Christians is against such a course of action, though the ethical basis of the feeling is not so clear. In spite of this, in some cases, notably in hydrophobia, it may be said that to a certain modified extent euthanasia is sometimes attained by the merciful administration of narcotic drugs. But we believe that a genera movement on the lines suggested by Mr. Wright is both impossible and dangerous.

Increase of Drug Habits.
In a recent interview with a London journalist a distinguished neurologist is reported to have said that in his opinion one of the chief causes of degeneration in the human race is indulgence in opium, or the drug habit. Apparently the degeneration of the human race is taken for granted, or it may be that it is so obvious a fact that there is no need to establish it. Our authority went on to state that Britain numberd her victims to the drug habit by thousands, and that the habit is commonest among ladies. Whether these words be somewhat sensational or not, no physician to whom it has ever chanced to treat a victim of the habit can regard the matter other than as most serious. In the ranks of our own profession also, there are we fear an undue proportion who are ruining their lives by the continuance of this stimulation. In America even more than in these countries the growth of the habit is such as to

CORRESPONDENCE.

You are always so fair to opponents that I feel I may thank you, Sir, in advance for so far trespassing upon your courtesy.

I am, Sir, yours truly,

EDWARD BERDOE, M.R.C.S., L.R.C.P.
London, December 17th, 1903.

DUMPING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—When I was reading the report in the Daily Telegraph of to-day (December 17th) of Mr. Chamberlain at Leeds," the following sentence (page 9, last column) rather struck me:—"Again he threw out a definition of dumping in one of his admirably crystallised sentences. What is dumping? It is buying in a market, it is selling below cost in order to get the trade."

It seems to me that a good deal of our hospital work is nothing but dumping. A very large amount of the hospital work is given for nothing, "in order to get the trade." The Charity Organisation Society has some knowledge of this, but has not been able to stop it, and they won't till the public and the profession wake up, particularly the general practitioners, as workmen generally are doing to the evil.

I am, Sir, yours truly,

QUEEN'S.

ANÆSTHOL AS AN ANÆSTHETIC.

To the Editor of The Medical Press and Circular.

Sir,—You refer in the Medical Press and Circular of October 28th, 1903, on page 475, in a brief abstract to my article published in the Journal of the American Medical Association, entitled "The Improvement of General Anaesthesia on Basis of Schleich's Principles, with Special Reference to Anaesthol," in which you state that "Anaesthol is of value in minor surgery only."

I am not prepared to quote the following from my full paper:—"I used anaesthol for the first time, October 15th, 1898, in an internal operation for appendicitis. ... Since that time I have used anaesthol almost exclusively in all operations requiring general anaesthesia, in hospital as well as private practice, that is, for a period of nearly four years. The only exceptions were such operations on the face, where I deemed pure chloroform preferable."

Further on in my article, Dr. W. C. Guth, of New York, an expert anaesthetist, the gentleman who has conducted the anaesthesia in the greater number of my private patients, outside of the hospitals, for the last eleven years, sums up his experience and says, on the basis of 200 cases of general anaesthesia conducted with anaesthol:—"For an operation of the major type, when complete muscular relaxation is to be maintained throughout, 60 grammes of anaesthol will be consumed in the course of an hour, or about 1 gramme a minute, if administered drop by drop." And further:—"Is a patient under the influence of anaesthol . . . complete muscular relaxation is established and maintained. Anaesthol combines the good effects of chloroform and ether and has its advantages over both," &c., &c.

In conclusion, in my original article I thus expressed myself:—"Believing Schleich's principle of improving general anaesthesia on a physical rather than chemical basis, to be correct. I consider anaesthol—produced as it is in true conformity with this principle—to be the least dangerous of all anaesthetics thus far known as they are employed for regular narcosis in the daily work of the surgeon."

As much as your abstract states that anaesthol is of value as an anaesthetic in minor surgery only, I trust you will oblige me by having this correction appear in your esteemed journal.

Very truly yours,

WILLY MEYER, M.D.

New York,
December 10th, 1903.
We welcome the introduction of this and believe that its merits will make it popular.

"Banamine" Flour is obtainable from facturers, Messrs. Josh. Appleby and of Liverpool, Bootle, Blackburn, England.

**NEW MEDICINE BC**

An enjoyable vocal and instragramme was then provided, after which it separated.

Wholesale Poisoning in Germany

It has been announced on good authorities that the last few days about fifty persons have been poisoned in Chemnitz, some of them seriously. The poison appears to be arsenic. An official inquiry is being held.

King's College Hospital Removal

The Drapers' Company have voted £600 towards King's College Hospital Removal. The decision is made upon the balance of the three hundred pounds required being raised by voluntary contributions within the year. Towards this sum the Daily Telegraph and Mr. Harry Lloyd, Chronicle, have each promised five hundred pounds.

Small-pox at Skipton

A further outbreak of small-pox is Skipton. The affected persons, who reside at Yard, are a man and his sister, together with a lodger. They have been removed to the hospital at Winterburn, and the rest of the family were isolated. At present it is not known how the outbreak was contracted.

An epidemic of cholera is raging at Kesh of Bagdad. Between the 9th and the 12th there were 216 cases and 176 deaths.

It has been officially stated that during the week there were twenty-one deaths in Erit from bubonic plague and twenty-five.

There are seventy-four cases under treatment.

Among other decisions arrived at by County Council at its meeting on 27th
it was resolved to exercise its powers under the Midwives Act 1902. The General Purposes Committee was instructed to make a report on the administration of the Act. This announcement is of considerable importance as regards the future administration of an Act that is fraught with good and evil. It has, moreover, a considerable bearing upon the welfare of the medical profession.

The Royal London Ophthalmic Hospital Guild has announced that a Centenary Festival will be held in the next spring to celebrate the completion of the hundredth year of the hospital's work. This guild is an association of friends of the old Moorfields Hospital who desire to promote its financial and social interests and add to the comfort of patients.

The Shropshire Scottish Graduates' Club held its first annual dinner on November 30th at Shrewsbury, under the presidency of Surgeon-Lieutenant Colonel Curton, V.D., M.D. It has been decided that the club, which is to be open to undergraduates, as well as graduates, of all faculties, shall hold its annual dinner on each recurring St. Andrew's Day. The honorary secretary is Mr. J. Hamilton, of Shrewsbury School.

The numerous attempts of medical men to protect their interests by a business-like organisation are reported from time to time with monotonous regularity. The latest comes from Pittsburg, Pennsylvania, where a number of medical practitioners have formed themselves into a Physicians' Protective Association. A black list of non-paying patients has been made out, and a schedule of fees established on a somewhat higher scale than formerly.

The executors of the will of the late Mr. Robert Munn have paid to the Victoria Hospital for Burnley and District £8,006, being the residuary estate of the testator bequeathed by him to the hospital.

The medical officer of health of the Cape Colony states that for the week ending November 21st only one case of plague was discovered in the Colony, that of a native male found dead on November 15th in King William's Town. Plague-infected rats were found at East London, Knysna, Lady Grey Bridge, and on board a ship in Cape Town harbour. As regards the Mauritius, a telegram from the Acting Governor received at the Colonial Office on December 11th states that for the week ending December 10th there were seventy-six cases of plague and forty-six deaths from the disease.

At the Congress of the Royal Institute of Public Health to be held at Folkestone, July 22nd to the 27th, next year, there will be a Section for Child Study and School Hygiene. Dr. George Gowers has been appointed London Secretary, and Dr. Percy Lewis local secretary. Gentlemen desirous of contributing papers should communicate with the local secretary. Those anxious to attend the Congress, who are not members of the Institute, can do so by taking a delegate's ticket, price £1 1s.

PASS LISTS.

The following medical and surgical degrees were conferred on December 10th:—Bachelor of Medicine and Bachelor of Surgery—R. T. Worthington, Trinity; H. L. Harnett, St. John's; and H. Pincnes, Sidney.

Bachelor of Medicine—R. B. Hetherington-Smith and H. H. Weir, Trinity; and J. E. Payne, Peterhouse.

Bachelor of Surgery—A. R. Brailey, Downing; Dr. D. MacAlister, Dr. J. H. Drysdale, and Mr. T. Strange.

The examinations for Part I. and Mr. D'Arcy Power and Mr. C. W. Mansell Moulin additional examiners for Part II. of the third M.B. examination.

Trinity College, Dublin—Michaelmas Term.

THE TREATISE
CHRONIC DISEASES

By CHARLES J. MACALISTER

Physician to the Liverpool Royal Infirmary for Incubiles, and to the Own

Many patients with incurable diseases are manifestly suffering more from the neglect of medical care than from any actual disease itself. In the external world, the main part of the disease is often more apparent than real, with the exception of localised cases. The nurse becomes the main care giver, often taking the place of the hands that once nourished the sufferer. In the medical world, a correct diet is often more important than the actual disease.

For instance, the matter is often more important than the disease itself. I have recently had an example of this. Two cases of chronic disease in young girls, who were incurable. I have referred to in a previous illustration of the points. One of these girls came under my care on 12th, 1894; she was 19, and had been to the beginning of 1895, when she was transferred to the Royal Infirmary for nine months. She was transferred there, for six months, to the old symptoms, which had been described as incurable. She was transferred there, for six months, to the old symptoms, which had been described as incurable.

She was transferred to the Royal Infirmary for nine months. She was transferred there, for six months, to the old symptoms, which had been described as incurable. She was transferred there, for six months, to the old symptoms, which had been described as incurable.

em both elsewhere, and, as some of you may recollect, I wish to elucidate my case. I have been the patient of the same 8 years, and my care on September 1, 1898, was not without success. I treated for ten months, although all disorders had disappeared from the face and trunk, there remained considerable swelling of the abdomen and of the lower extremities; the albumin had diminished. But she was in a fair condition, with the object of stirring up her lymphatics, I ordered that drug concerning which the text-book warns us so carefully in Bright's disease. I refer to mercury, which was rubbed into the abdomen night and morning, and the effect was magical, for within a fortnight the swellings had gone from the legs and abdomen, and two weeks later not a trace of oedema remained anywhere.

The abdomen then measured 28.5 in. respectively; the left ankle 10.5 in., the left thigh 15 in., the left calf 10.5 in., the left knee 15 in.; and the girl looked and felt a great deal better.

Sad to say, this girl, after exactly three years of comparative health, died of a uremic attack, the result, I feel sure, of her inability to limit her food requirements. Her renal inadequacy was much more marked than in the case of the former patient, and she never could be allowed the same amount of nitrogenous food.

I have during the last two years had a similar case to these in a little girl, whose dropsy and uraemia, after long persistence, disappeared in the most satisfactory way, but after all my pains and her patience she contracted diphtheria and died.

Looking back upon these cases, I cannot help feeling some satisfaction that the treatment of long-continued dropsy and chronic uraemia may be followed by good results, and that careful attention to the dietary and eliminative processes of the patients after the

been elaborated and extended in a recent paper by Woods Hutchinson. Evidence for or against this theory is difficult to obtain from the human subject, and it is therefore advisable to have recourse to the study of the comparative pathology of the disease. In this direction we may make a study of the disease, either as it has occurred naturally or as it has been experimentally induced. The former is much to be preferred. The author's communication consists mainly in an account of the post-mortem appearances in a case of gout naturally acquired in a fowl, with a brief statement of the manner in which the observed facts are interpreted. Reference will also be made to some results obtained in an experimental research on the disease.

(A) Gout in a fowl in which the disease had run its natural course. The clinical record shows that the fowl was observed to be out of sorts for a few days, its comb became dusky, and it was found dead. (A few days later a fowl of the same brood showed similar symptoms and died.)

A post-mortem examination showed:—(a) The synovia in some points of the colonic consistency of cream; it readily gave the murexide reaction; (b) a deposit of urate of soda, &c., in some extra-vascular tissues, mainly round the smaller joints; (c) recent pericarditis; (d) widespread thrombosis, notably in the liver and heart; (e) pronounced congestion of the liver and kidneys; (f) areas of “necrosis” in the kidneys. The bone marrow was not available for examination. A microscopic examination revealed other morbid conditions, notably: (g) catarrh in the intestine, especially in the ileum duodenum and large intestine; (h) the pancreatic ducts filled by catarrhal products derived from their lining membrane; (i) the spleen was congested, the endothelial cells of the sinuses were proliferated, and there was a marked increase in the number of granular leucocytes; (j) tubular changes in the kidneys, mainly involving the granular leucocytes.

The gouty deposit in the tissues, the changes in the synovia, the venous thrombosis, the terminal pericarditis, and the areas of “necrosis” in the kidney are in perfect harmony with those appearances in the human subject. Particular interest centres in the condition of the intestinal tract, pancreas and kidneys. The post-mortem appearances are characteristic of a bacterial infection. The changes in the blood have special interest in connection with the changes in the blood in acute gout recently described (Chalmers Watson—Bain). Have the changes in the pancreatic duct any significance re gouty glycosuria in man? The author emphasises the necessity of further examination in the comparative pathology of the disease, and more especially of tissues obtained sufficiently fresh to allow of an adequate bacteriological investigation.

(B) Allusion to some results—clinical and pathological—obtained in a research comprising the feeding of fowls on a diet of meat and water for a period of from 3 to 15 months (illustrated). See paper by Kionka Archiv für Exper. Path. and Pharmacol., 1900. Special attention is directed to the bone marrow.

Some Theoretical Considerations.—There is some evidence in favour of the view that the special attention directed to the “purin bodies” as important etiological factors in gout will be productive of as little advance in our knowledge
of cerebro-spinal fluid effusions, and to effuss into joints. In these cases, the fluid may be prevented by centrifuging, or the process until the fluid has been effected in a few minutes, small glass spheres. If fluid that has not coagulated process of coagulation is say how far the cells are done immediately of these fluids coagula may be prevented by solution, or the process until the fluid has been equally mixed with the small glass films are made. This is the mixture on slides or covers in the air. For the cases doubtful cases it is better to be done in the cells and allows the cells to be a subsequent counting. With the dried film stains that the details of the defect can be obviated by after centrifuging by non this up with the deposit if necessary, repeating the forming the deposit come containing little albumen minus fluid by normal necessary, and should be present of glycine is done by alcohol and ether method, as in the case of b.

The stains chiefly used are methylene blue and eosin, or other of its modification: as recommended by Pappe of Ehrlich.

The triacid stain is not of the case of blood films, biles are often altered so as up stains. It will be remost labile part of the cell, tions, when they are badly fixed.

It is often of advantage, to use two or more staining done as in blood films.

The cells that may occur in cancer cells, are—Red blood cells; mononuclear cells, and endothelial cells.

Of these, red corpuscles show their percentage of the total cells occurred were so very vary conclusion can be drawn for our purpose they may be
利亚 and peritoneal tunica vaginalis and peritoneum, the results obtained through generally accepted formulas are not those of fluid from the

The lymphocytes, polymorphonuclear neutrophile cells and endothelial cells are all of importance.

The recognition of the different varieties of cells in blood films is very easy, but in films made from effusions it is often very difficult. This difference is due to the fact that, while in blood we meet generally with no degenerate cells, in serous effusions some of the cells undergo such changes as render them liable to be mistaken for cells of a different class. It is necessary to describe some of the more important degenerative forms, as obviously failure to recognize their existence may make important differences in the results obtained. Indeed, it is probable that some of the discordant results obtained may be thus accounted for.

The polymorphonuclear neutrophile cells are liable to undergo two changes, in both cases with the result that they appear mononuclear:

1. The different segments of the nucleus may swell, and may come to lie so close together that the nucleus appears to be a single rounded mass. On careful focusing, however, a space can be made out separating the different segments.

2. The nucleus may break up into rounded fragments. This division is followed by division of the protoplasm, so that each portion of the nucleus becomes surrounded by a layer of protoplasm.

Ehrlich first described these bodies in an exuatio puerperalis seminalis, and called them "pseudo-lymphocytes." He described them as "about as large as a small lymphocyte, having a rounded nucleus which stains deeply, and a narrow layer of protoplasm containing neutrophile granules." He considered them rare, but Wolff has found them not uncommon in pleural effusions. When the neutrophile granules can be stained in these two degenerate forms of neutrophile cell no difficulty in their recognition can arise, but when, as is frequently the case, staining cannot be accomplished, their recognition is a matter of difficulty, and hence their distinction from lymphocytes needs special care.

The following points will assist in distinguishing pseudo-lymphocytes from lymphocytes:

1. Neutrophile granules may be found in them.

2. Their zone of protoplasm is generally wider than that of lymphocytes.

3. They are naturally more common in effusions of a polymorphonuclear character. This would probably prevent a mistake occurring, as only a few of them are likely to be mistaken for lymphocytes by anyone of experience.

4. When stained with methyl-green pyronin their protoplasm only takes on a light rose colour, while that of polymorphonuclear cells stains a deep red.

The changes in endothelial cells are of less importance than those in polymorphonuclear phagocytes. Their nuclei may swell and come to lie excentrically, and they may resemble large mononuclear cells of the blood, but are always too large to be mistaken for lymphocytes.

I shall now reter in more detail to the results obtained in different effusions, and I shall first speak of effusions into the pleural cavity, as in these the results have been most consistent. In primary tuberculosis effusions, Widal and Ravaut found lymphocytes almost exclusively amongst nucleated cells, while others or less considerable number of red corpuscles. Occasionally they found a few cells which were either large mononuclear or altered endothelial cells. They never found large flakes of endothelium, but they considered it not improbable that these might be found at a very early stage of the affection. Polynuclear leukocytes were always less than 10 per cent.

Wolff, Barjon and Cade found that the cells vary greatly, such variation depending on the time, after the commencement of the attack, at which the fluid was taken.

It may be stated that polymorphonuclear cells are always present in the early stages—about 10 days—of pleural effusions of a tuberculous nature. The earlier the case, and the more acute the onset, the more polymorphonuclear they are. Their cytological formue may therefore be of an acute infectious effusion, and before having faith in Widal and Ravaut's cytological law it is necessary to know the date of onset. During the first ten days

t with the views of those who believe their cytology, as have been recorded, is accompanied with polyneuroidosis in non-tuberculous cases. Polyneuroidosis has been seen in the saphenous veins and to come to cytochemical. The differential method with meningomyelitis and meningomyelitis in many cases, is quite constant in meningomyelitis, and in any other affections of the spinal cord. It may also serve even in a very early stage of the disease. Further research, and investigations for practical use, will establish the fact that tuberculosis is really characterised by this new disease.

The results of cytology can only be properly understood by those who have been influenced by the observations of the late Dr. Johnstone. There are many points which call for further work and on the part of the medical profession, general support that to take its place of clinical diagnosis.

Tuberculosis of Consumption.

By AL. COMMISSIONER.]

UM, BOURNEMOUTH. Additional Sanatorium for the Chest, at Bournemouth; for the reception of patients suffering from consumption. Structurally among modern sanatoriums, many disabilities exist as far as possible, hygienically, old-fashioned. It is ugly, substantial, and old-fashioned, and, by architectural feature, tractiveness. The sanatorium is a well-known and well-protected one, but the site has an extensive sort, and many medical station for tuberculous cases. Its serious disadvantages are its unconcealed position and the small building from the south-west. A small chapel is used as promenades, are on the south. The dining-rooms, although far from complying with modern requirements, are well lit and fairly well ventilated. The wards vary in size, some having beds for five patients, others for three, and a few are single bedded.

Improvements are being made. The old sash windows have been replaced by double casement windows with fanlights. In order to improve ventilation, and procure more light for the corridor, one window has been fitted up with openings under the ceiling in the party walls, two feet square, with two feet between each aperture. Curtains can be drawn along rods afford to patients a certain amount of privacy for dressing. There are open fire-places. Apertures have been made in the lower parts of the doors. Evidently much pains are being taken to procure as near an approximation to open-air methods as the antiquated character of the building will allow.

The sexes are kept strictly separate, as certainly seems most desirable in such an institution.

The grounds are well adapted for resting in the open air, but are too limited for the taking of much systematic exercise. The proximity of the Mount Dore Hotel, which adjoins the sanatorium and various private residences, makes it impossible to employ bungalows or night shelters. There are, however, four fixed and three revolving day shelters, with other conveniences, all lighted by electricity, which are of much service in wet and windy weather. Suitable cases are allowed exercise on the sea front or in the sheltered public gardens.

There an accommodation for 65 patients, an equal number of each sex. An extension is contemplated which will provide space for six or eight additional beds and furnish better accommodation for the working staff.

The objects of the institution as defined by the original trust deed of 1855 are "to afford a temporary asylum for in-patients afflicted with chest diseases, who (1) being convalescent; may yet require further medical treatment and change of air to establish their health; or who (2) may be labouring under such an incipient form of disease as to afford reasonable hope of their obtaining benefit from a temporary residence in a dry and salubrious climate." No male under seventeen, or female under sixteen, years of age, is eligible for admission.

Admission is obtained only by a nomination (letter of recommendation) from an annual subscriber of three guineas, a life governor (constituted by a donation of £100) or from a donor of £5.

On a patient's case being approved by the medical authorities, his or her name is entered upon the books for admission in the order in which the nomination is received, due notice being given to the patient when the time for his or her admission arrives.

Patients make a weekly payment of seven shillings and sixpence, which covers all expenses except washing, and are entitled to remain in the sanatorium as long as may be considered desirable by the physicians. Should it, however, be deemed necessary for the patient to remain in the institution a longer period than twelve weeks, a second nomination must be obtained.

Among the 29 commandments, or, as they are called, "Rules and Regulations for Patients," reference to the following may not be without interest:

"As members of a well-ordered community, patients shall attend the daily morning and evening prayers; also Divine Service on Sunday morning and evening, except when they have a certificate of leave to attend a Nonconformist place of worship. Patients on their first arrival at the institution will be required to declare to what religious denomination they belong. Non-conformists may be visited at reasonable times by ministers of their own persuasion, and on Sunday mornings they will be permitted to attend their respective places of worship, on receiving a separate permission in writing, on each occasion, from the medical officer. The hours, as at present appointed, for daily morning and evening prayers, are at 9 a.m. and 7.30 p.m.; for Divine Service on Sundays,

terill: (1) Fracture through seventh cervical, dividing
cord. (2) Stricture of bowel from tuberculous peri-
tonitis. (3) Specimens from cases of ectopic gestation,
(4) Prostate removed from man, et. 75. (5) Chondro-
sarcoma of leg.

By Mr. Catichart: (1) Plate of teeth swallowed
and vomiting again. (2) Remarkable chart from a
case of burn.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
SECTION OF SURGERY.

MEETING HELD FRIDAY, DECEMBER 11TH, 1903.

The President, Sir Lambert Ormsby, in the Chair.

The following living exhibits were shown:—Mr.
R. F. Tobin.—(1) Cases of excision of knee-joint. (2)
Case of hypertrophy of prostate radically cured.
Mr. D. Kennedy.—(1) Two cases of talipes after opera-
tion. (2) Relapsed case after operation.

The following card specimens were shown:—Mr.
R. C. B. Maunsell.—(1) Aneurysm of abdominal
aorta treated by the Moore-Corradi method. (2) En-
larged prostate (5 oz.) removed from patient, et. 75.
Mr. D. Kennedy.—(1) Skiagraph of fracture of lower
end of humerus. (2) Skiagraph of extreme curvature
of tibia in infant, et. 9 months.

Sir Thomas Myles read notes of a case in which
he had removed a large
pyloric tumour and nearehalf the stomach and
first stage of duodenum.
The patient was a woman, et. 32, weighing only 50 lb.
Tumour situated at right side of middle line, supposed
to be a distended gall-bladder, as there was a history
of two previous attacks of jaundice and colic. Incision
in mid-line showed a large tumour of pyloric area.
Operation carried out as follows:—Duodenum clamped
and divided, distal end closed with purse-string sutures;
stomach clamped about centre, divided, and proximal
end closed by double row of sutures. Vessels care-
fully ligatured along upper and lower curvatures to
point of division. Tumour area carefully separated
from bile-duct and portal vein; found adherent to
pancreas; had to be stripped from it, leaving raw
pancreatic surface. Great omentum removed enti-
tirely, and jejenum brought up to stump of stomach
posteriorly, but in front of left end of colon, and fixed
by means of a Murphy's button. Operation occupied
two hours and ten minutes; was followed by great
shock, lasting nearly thirty hours. Eventually com-
plete recovery.

Sir Thomas Myles then gave short account of fifty-
one cases of operation for stricture of the stomach.
In four pyloroplasty had been performed, with one
death, in forty-seven gastro-enterostomy without a
single death. Operation had been undertaken for
malignant and fibrous stricture of the pylorus, and
for simple atonic dilatation with persistent vomiting.
More than half were done with simple sutures, balance
with Murphy's buttons, the last fourteen in series had
been done with the button. Sir Thomas Myles urged
the advisability of gastro-enterostomy in atonic dilata-
and in intractable non-malignant ulceration of

Mr. R. Charles B. Maunsell read a paper entitled
the surgical treatment of abdominal aneurysm.
He dealt fully, but concisely, with the modern literature
of the subject, illustrating his remarks by means of
drawings, tables and dissected specimen. He then
related the history of a case which he had treated by
the Moore-Corradi method, introducing six yards of
silver wire, and passing a current of 65 ma. for thirty-
five minutes. The patient was considerably relieved
but died on the forty-seventh day from hæmatemesis,
cases, the motility of the joint was poor. In general one should not aim for but for firm support from ankylosis the limb could not be avoided, but o
The social condition of the patient to be taken into consideration in the conservative treatment lasted from to recovery was more rapid from operative treatment the first care of the general condition and to improvement. Children did best at the statistics of Leroux dealt with the He had 61 recoveries, 19 improvements were stationary, and 63 per cent. seven to ten years 65% per cent. well fit for work.
The injection of soft soap had no adjuvant. It served to improve
dition.
As regarded local treatment, the part of the joint was the first care. ceased at once. Then came the surgeon immobilised and the patient apparatus for walking, so that he in the open air. This could be supported. In France camphor napl came much used. Ten to fifteen injective inures. Landerer recommended Before commencing treatment of straightened out, but not forcible Abscesses did not preclude ambulation.
Bier's stasis was now modified. was now employed only for one abscesses and fistulae healed rema In four to eight weeks even serious of the ankle-joint healed. Many cases of operative measures had adva during recent years. In earlier days resection cases died. Now the per cent. The functional results and recurrence readily took place, ended fatally. Operation should minimum, and only carried on threatened life.

Lang said the case presented was nothing more than

one of cutaneous epithelioma of the nose. Paget’s

disease properly described was a circumscribed chronic

epithelial dermatitis.

Eiselberg related the results of his former assistant,

who devoted a considerable amount of his time to

the subject in order to differentiate this disease from

any other form of cancer. The conclusion he arrived

at was that the pathological change present in Paget’s

disease was an indisputable form of cancer, indi-

istinguishable from epithelioma elsewhere.

Matzner rally by saying that the histological

examination of Paget’s disease revealed two characters

peculiar to itself, and therefore was a perfectly distinct

disease that might occur anywhere in the body. First,

the morbid change was found between the epithelial

layer and the cutis vera as a wedge infiltration whose

plasma gave genuine proof of its malignancy. The

second distinguishing character has frequently been

referred to—viz., the tendency of the flat cells to

harden, which confirms the clinical observation of a

leucoplasia becoming in time a dry hard cicatri-

trial-looking growth, more particularly when occurring

on a mucoid surface.

Holzheuck again exhibited the sections he had

shown the members on a previous occasion, where

the disease presumably commenced at the axilla, and

thence extended across the chest and down the arm.

He thought these sections conclusively proved all that

had been advanced concerning the disease as capable

taking its origin anywhere on the body.

ECTRODACTYLUS.

Lorenz next brought forward two brothers, 22

and 24 respectively, with abortive toes or digits.

The palm of the hand was somewhat defective, while

the terminal part appeared as one finger, resembling

the little finger. The foot was cloven, or split into two

toes—a large and small one.

Notwithstanding this defect or malformation, the

patients were able to perform the most complicated

duties, even to the striking of matches. According

the family history, the mother and four other

brothers were so formed. Two other brothers who

died young were similarly malformed.

BONE TRANSPLANTATION.

Wagner showed a patient on whom he had operated

with success on the frontal bone. The patient ten

months ago received a violent blow on the forehead

with an iron ball, which destroyed a portion of the

frontal bone, through which the brain protruded after

the wound was healed over. The defect in the bone

would be about the size of a five-snitting piece, through

which the brain jutted forward to a great extent when

coughing. Every pulsation could be plainly felt by

the observer, and even seen when carefully examined.

He took a lamella of bone from the tibia and applied

it to the raw edges in the cranial opening, which

shortly healed and closed the bony opening completely.

ill be not only greatly
more substratum of cold
d what is this nobleness
the nobility of birth, of
not be even the nobility
ility arising from a sense
over sickness, a power

over sick people. For we are masters in the sick-
room; not in virtue of commission or patent, but
in virtue of our knowledge, and in virtue of the
trust reposed in us, and we are impelled by our
honour to stoop to help the afflicted to the utter-
most and to the last. If we are conscious of our
nobility, we shall not be lightly touched by the
sneers, the rebuffs, the malignity of others. We
shall be able to excuse them on the same ground
that the inflexible Cato excused those who fell
short of his own lofty standards of conduct—as
he pointed out with pity that they were not Catos,
and therefore not amenable to so high a tribunal
of honour as himself. "Nobility," said the learned
Bacon, "extinguisheth the passion Envy from
others towards them; Because they are in posses-
sion of honour." The honour of our profession is
a peculiar and priceless possession, a trusty guide
to conduct and a sacred heritage; "it answers
faith in things divine." And if the honour of our
nobility makes demands on us in our external
dealings, how much more so in our internal de-
dealings the one with the other! The relation of
the medical man to his fellow medical man is an
anomalous one; he is at the same time his colleague
and his rival, co-operating in his profession and
antagonising in his business. It is almost im-
possible but that occasions should arise when
"jealousy with rankling tooth" should "inly
gnaw the secret heart" when the success of one
exceeds the other, and almost equally so that
misunderstanding should occur. But these need
not endure. We are all working for the same end;
we are all actuated by the same honour; we are
all bound by the same obligations of nobility. If
we feel thus, however outside misrepresentation or
even malice may seek to divide us, we "shall
brothers be for a' that." Let us keep our nobility
untarnished, high above the people we serve,
knowing that it is something which they cannot
attain to and cannot perhaps understand, but
something that is to us very real, and something
producing very tangible results. We cannot take
a better watchword for the New Year than the old,
trite, but evergreen motto, "Noblesse oblige."

PROPOSED UNIVERSITY FOR SHEFFIELD.

The rapid development of higher education in the
United Kingdom is being registered from time to
time in emphatic form by the foundation of new
universities. The latest movement of this
kind it is our pleasure to record was inaugurated
at the meeting of the Midland Medical Union held
at Chesterfield on Tuesday, December 8th, when
a resolution was adopted cordially supporting the
movement for a university for Sheffield. At the
annual dinner the same evening Mr. Simeon Snell,
who is one of the honorary secretaries of the
university movement, was called upon to speak
about that project. In doing so he acknowledged
the cordial assistance which was being rendered by
the outlying districts. He announced the inter-
esting fact that Chesterfield had been particularly
conspicuous for its friendly attitude and by its
promises of financial support. The reason for
their friendliness was not far to seek, inasmuch as
bearing out the considerations of two brochures, "The Failure of Hospital," by Dr. Dean Monro, Influence of Hospital Isolation by Dr. Killick Millard. Two are, first, that the influences of the rise and fall in scarlet fever are widespread and little known, contact is only one of a set of factors to this end; and, second, machinery for eliminating this is either faulty in itself or knowledge, or both. Scarlet fever first recognised has shown, like diseases, a wide variation in prevalence, and its present wide distribution and low rate it had assumed before isolation. But not only is there no partial restriction of the incidence of the disease, it should surely have manifested itself here this, but there is a still more marked aggregation, namely, that where cases together, with hospital and care, have brought it. It is a commonplace of it that outbreaks are those for which the patient is so difficult to guard against means inconsiderable patients will always be exposed and measles, to say nothing of other diseases. Moreover, from the infection of criterion, and every carefully managed, patients who go home disease for which they are Three questions suggest themselves: they were introduced into the system inherent in it. Are the enormous savings justified, or could they have been? These are grave matters of demand for consultation, and a representative body is sought for by Dr. Killick Millard and others. We have support, for when the laity the question of local professional is not likely to be damaged prestige.

Notes

Payment

We are pleased to announce a new scale of charges which includes your cases which have been attended by your Secretary, and we believe the scale is the one that Dorington's C...
Legal and medical witnesses .... 1 gn.
Ditto (two or more cases) .... 2 gn.
Ditto (over three miles) .... 2 gn.
Solicitor for prosecution .... 6s. 8d.
Expert witnesses .... 1 gn.
(Expert analyses, medical examinations, plans, &c., extra at discretion of Court.)
Interpreters .... 1 gn.
Ordinary witnesses, maximum .... 7s.
Ordinary witnesses, if detained all night .... 5s.
(These allowances are double the old rates, but the maximum is not always to be given.)
Children, servants, and unemployed .... 1s.
Labourers .... 3s.
Artisans and mechanics .... 5s.
Others .... 3s.
Night allowance .... 5s.
(Only half these allowances to be paid if detention is under four hours.)

It may interest medical readers to note that first-class fare is not to be allowed "unless there is reasonable ground for supposing that the witness ordinarily travels first-class." The increase in the case not only of medical but also of ordinary witnesses does a great deal towards the removal of a long-standing grievance against the administration of criminal justice in the United Kingdom. It is to be hoped that many other much-needed reforms will follow, such as the establishment of advisory expert boards instead of the present loose system of opposing expert evidence, and the granting of free prosecution in criminal cases.

The Contamination of Milk.
The laws to which human society is subject are, in principle, very similar to those which govern the lower world of Nature. This parallelium is well exemplified by the fact that for a privilege enjoyed by any living creature some risk must be undergone, some liability incurred, or some penalty imposed. For the gratification of his palate by the ingestion of a choice morsel the beast of prey has to traverse, perchance, immense distances under conditions which must lay him open to the attacks of an adversary stronger than he. Likewise man, who at the first stage of his existence is dependent upon milk for his sustenance, is exposed to considerable danger in the consumption of that necessary article of food, owing to the presence in it of the ubiquitous disease germ which may prove for him to be only too powerful an opponent. At least, so it would seem from the perusal of the very interesting report by Dr. George Newman, Medical Officer of Health for Finsbury, upon the milk-supply of that borough. As there is no reason to suppose that the supply of milk for Finsbury differs materially from that of other parts of the Metropolis there is only one conclusion to draw from the report, and that is that a grave danger exists in our midst from the consumption of contaminated milk. A large proportion of milk is derived from country farms, and as a considerable number of these are situated at a greater distance than one hundred miles from London most of the milk is already twelve hours old by the time it arrives at the milk-shop. The chances, therefore, of bacterial
and colleges are very insistent privileges, and thus oppose the practitioners for proportional representation of the body of the entitle them to an overwhelming majority if this ought to be secured to the commerce tax is levied. Till this demand is one obvious reply to the request and one which the bodies concerned It is to be hoped that there will be a continuation of the object-lesson of the past in domestic politics. Another is that which we shall call attention to is that if medical men are entitled to a yearly fee to the General Medical Council, they will be entitled to demand for competition against the unfair competition of practice to which they are subjected.

The Teaching of Gynaecology of Childbirth

We learn from a competent examiner in gynaecology and the Royal University of Ireland that representation to the Senate of the effect that, in their opinion, students should return to the practical work to furnish evidence of clinical instruction in gynaecology and childbirth. Although these present time to unduly unduly courses that must be attended appears to us that to free oneself from the necessity of receiving instruction on subjects, while at the same time passing an examination subjects are of importance clinically. If they are not taught them to his curriculum of the practitioner some knowledge is essential, but for the attempt that cannot be obtained it can be gleaned in the profession.

We presume the University has freed the student from clinical instruction of children with the extent an overwhelming question arises, where subjects could have been taught appears to us that to set up at the expense of the University for examination purposes, to omit the short course would—to some extent—take away from him how to apply the gynaecological policy, and is akin to staring to the well.

Hospital Medicine

The lot of the medical surgeon to a large extent an easy one, as for the large amount of work they called upon them to do into the deaths
at as regards their

falls and Inquests.
 honorary physician or
ual charity is by no means
of such a post demand
end attention. Were
oder inquirer’s inquiries
nder their care the
burden, would speedily become intolerable. Fortunately in the case of in-patients the evidence of
resident medical officers is accepted by juries in all but important criminal cases. The hardship of
the honorary out-patient physician or surgeon being
required to attend inquests would be a thousand
times greater. It is the habit of many of the
poorer classes to put off seeking medical advice to
the last moment of an illness, when a single visit is
paid to a medical man or to a dispensary or hospital.
In too many cases a death certificate is granted on
the strength of that single interview, and the
unpleasantness of the official inquiry into
the cause of death is thereby avoided. In the
case of a child, aged ten weeks, who died the day
after a visit to the Queen’s Jubilee Hospital,
London, the Fulham coroner held an inquest. It
was ascertained that the child’s case had been
diagnosed as “bronchitis.” The assistant phy-
sician declined to attend the inquest, and the jury
stated their opinion that he had acted
courteously both to the coroner and to themselves
in adopting that course. From independent medi-
cal testimony it was shown that death was due
to broncho-pneumonia. The jury added a rider
to their verdict to the effect that they con-
idered “the doctor at the Jubilee Hospital might
have given more attention to the case.” Anyone
 acquainted with the exigencies of out-patient
practice must see the hopelessness of devoting
detailed care to each one of the patients that
crowd the waiting rooms of our hospitals. If any
enure were needed in the Fulham case it would
have been more aptly bestowed on the mother
who so unwisely exposed an infant, sick and of
tender age, to the risk of such a visit.

The Continental Traffic in Old Horses.
For many year past public attention has been
directed from time to time to the large traffic that
goes on with continental purchasers of our worn-
out horses. It is an open secret that these animals
are bought for human food in the shape of sau-
sages and other meat preparations. With the use
of horseflesh as food we are not concerned, it is a
mater of sentiment to be settled entirely by the
individual judgment and it is quite possible or
even probable that the inhabitants of the United
Kingdom are depriving themselves of a valuable
food supply simply and solely through the exercise
of a logically indefensible prejudice. The fact
remains, however, that our refusal affords the
Belgium buyer his opportunity. The only way in
which this curious traffic can be controlled is by
putting into action the laws against cruelty to
animals, and against the spread of contagious
diseases among the lower animals. A host of
persons have been punished for cruelty in deporting
lame and broken-down horses. It is doubtful
whether the veterinary inspection of exported
animals under such circumstances has been hitherto
properly carried out. Only last week one man was
fined in the Southwark Police Court £3 and £1 1s.
costs, and another £5 and £2 2s. costs; one for
having in his possession a glandered horse and the
other for leading the animal through the streets.
the huntsmen the meeting was set in motion in the Lord Mayor to come for food. Dr. Colling was fever in the city to a trade as "Gann's" in Thames Street. An application to the City submitted to the Chief Them contaminated by consumption. The application so as to peak of the main stock directed that his view to the vendors interest. Company, with a view to sale of the incriminating Fishmongers' Companys' simple way of earning so long will the public assertions. A plan particular mark was noticed some time since trade languishes and risks of a wholly avowed. No responsible medical conditions advise his

The Lurking Plague

The modern crusade is concerned with a fact only by his secrecy shows that much of tubercle bacillus is soil of the most interest medical historian while of the disease between animals. The habits house and in street a wide field of inquiry question of immunity demands patient and. There can be no query in this particular instance individuals, so much of mankind practice of the disease. For that all of us, especially be repeatedly exposed. As a matter of fact root, as it were, only been lowered by previously diseased up our minds to other specific bacteria we banish this scourge report of the medical. In chester we learn were registered during Notification of the 102 were Public Health Office. Of the cases regi
were in the common lodging houses of the city. The amount of infection that must lurk in these numerous centres, known and unknown, must be simply enormous, when one takes into consideration the extremely chronic nature of phthisis. Some day the principles of common-sense prevention will be rigorously applied to the control of consumption.

"Dirty Dick" as Temperance Reformer.

Reform that comes from within the walls is far more likely to be quick and effectual than that which is adopted perforce from opponents without the walls. On that ground the application of a sound principle may be welcomed even though it hail from an unexpected quarter. In London, as most men know, there is an ancient hostelry, established in 1745, and known by the historic name of "Dirty Dick's." Under the conditions of the will of the original owner, Nathaniel Bentley, who was of eccentric habits, the shop was left in the enjoyment of dense festoons of cobwebs until they were disturbed in 1870, when a part of the tavern premises became so dangerous that it was rebuilt. The liquor sold at "D.D.'s," as it is familiarly known, is only of the best, for originally, and presumably in the present day, only a small margin of profit was permitted. This central fact of good liquor alone being supplied to customers is in itself an undoubted aid to temperance. It is a well-known fact that bad liquor is accountable for much mad and riotous drunkeness, as well as for a large proportion of the damage done to the internal organs of its consumers. But the greatest temperance effort of Nathaniel Bentley stands recorded to all time in the rule—the golden rule—that no person is to be served twice, and no person at all if he be the least intoxicated. Were this law to be applied universally in the United Kingdom we venture to think it would do more to rid our population of the terrible evils of drink than all that temperance reformers have effected for a century. Let any vicar of a country parish think what it would mean if he could persuade the local publican and the local squire to treat this matter with the sound eccentricity of old Nathaniel Bentley.

The proof of porridge, like that of beef and plum pudding, lies in the eating thereof. That direct and practical test has been applied for centuries by two dominant races, and each appears satisfied with the result. The Scotch point to their ancestral triumphs of mind and body which they ascribe mainly, so far as can be gathered, to the powers begotten and sustained by "parritch," eked out and rounded off, as it were, by a "wee drappie o' mountain dew." The Englishman, on the other hand, refers to the enduring monuments erected by his forbears in intellectual, military, naval, and commercial fields, and proudly, if somewhat curtly, intimates that the whole of that stupendous structure rests on a basis of beef, beer, and plum pudding. Where lies the truth between these apparently conflicting national assumptions?

Obituary.

Mr. BERTHOM THOMAS READ.

We regret to announce the death of Mr. Bertram Thomas Read, a medical practitioner of Odham, at the early age of forty-two years. Mr. Read was fulfilling his usual duties when he was taken seriously ill. The symptoms developed into a severe attack of perforative appendicitis and peritonitis, and he passed away about half past six on December 12th, after undergoing an operation. Mr. Read studied at University College, and in 1887 took the M.R.C.S. and L.R.C.P. of London. He settled in Odham in 1898, and was appointed to the post of medical officer to the Odham District of the Hartley Wintney Union.

DR. WILLIAM HENRY KEMPSTER.

The death is announced of Dr. William Henry Kempster, who held several public appointments in Battersea, and was surgeon to the V Division of Metropolitan Police; he died at Chesterfield, North Side, Clapham Common, in his seventieth year. In 1881 he qualified M.B. Durham, as M.R.C.S.Lond. in the same year, and as D.P.H.Lond. in 1889.

Central Midwives Board.

At a meeting of the Central Midwives Board, Dr. F. H. Champsseyns in the chair, held on December 17th, the following business was transacted:—

1. The report of the Standing Committee as to the principles on which the Board should act in dealing with applications for recognition under Section C. of the Rules as approved institutions, or as approved teachers, was considered, amended, and adopted.

2. In accordance with the recommendations of the Committee the Board resolved:—(1) To accept the signature to Form V. of registered medical practitioners who are (a) past or present holders of appointments to lying-in institutions or maternity charities, or (b) past or present examiners in midwifery to any examining board for a medical qualification, or (c) lecturers on midwifery to institutions where pupil midwives or students of medicine are instructed. (2) To consider individually, and on their own merits, applications from registered medical practitioners not coming within the above categories. (3) To postpone for the present all applications from teachers in Poor Law institutions in view of the fact that almost all midwives exercising their calling in such institutions are (at the express instance of the Local Government Board) specifically exempted from the operation of Section E. of the Rules.

3. The following applications for recognition as approved institutions under Section C. of the Rules were granted: Queen Charlotte’s Lying-in Hospital; Liverpool Ladies’ Charity and Lying-in Hospital; Manchester Southern and Maternity Hospital; British Lying-in Hospital, Newcastle-on-Tyne Lying-in Hospital; General Lying-in Hospital, York Road, Lambeth; Glasgow Maternity Hospital; Dundee Maternity Hospital; District Nursing Association, St. James Square, Cheltenham; Maternity Charity and District Nurses’ Home, Piaestow.

4. The Board resolved that a slip be appended to Form III. of certificate of attendance on cases) as follows: “Note.—Although a case of labour may be used for the instruction of more than one pupil, the case can only be counted to the credit of the one pupil to whom the actual delivery is entrusted.”

5. After consideration of applications for certificates the names of 270 women were placed under Section 2 of the Act, and ordered for entry on the roll. Of this total, 55 claimed as holding the certificates of the Obstetrical Society of London; 5 that of the Rotunda Hospital, Dublin; 1 that of the Coombe Lying-in Hospital, Dublin; 1 that of the Liverpool Lying-in Hospital; 8 that of St. Mary’s Hospital, Manchester; 2 that of the Salvation Army Maternity Home, and 186 were admitted as having been in bond fide practice for one year prior to July 31st, 1902.
